Dr. Robert Smith (Harmonics, p. 220 and 271), calculated about the middle of the laſt century, that the tenor clef C note, upon the organ in Trinity college, Cambridge, made $232\frac{1}{2}$ complete vibrations in 1″, or 2322 in 10″, which, he ſays, was above half a mean-tone lower than the London *opera pitch* at that time, and which therefore probably gave about 2460 or 2470 pulſes in 10″. The above experiment of Dr. Smith's was made, after Trinity college organ had been depreſſed a whole tone in its pitch, by making the keys each to act on two pipes lower in the ſcale than they originally did, by which it was reduced (Harmonics, p. 208, and 218) to the Roman *pitch*, or that to which the pitch-pipes, made about the year 1720, were generally tuned. Dr. Thomas Young, in his lectures at the Royal Inſtitution (Syllabus, p. 95), ſtates our C to make 256 vibrations in 1″, apparently only, for the purpoſe of agreeing with an imaginary C eight octaves below, which is to make but 1 vibration in 1″, but which imaginary C, according to the recent determinations of *concert-pitch*, which we are about to mention, ought to make but the $\frac{15}{16}$ part of a vibration in 1″, the 8th octave above which will be moved at the rate of 2400 pulſes in 10 ſeconds.

The late Dr. Robiſon applied our ſecond, third, and ſixth methods, for determining the complete vibrations made by C, and ſtates them all to agree extremely near with 240 in 1″, or 2400 in 10″. Many other experiments are upon record, but generally ſome other note than C was ſelected for the experiment, the exact interval between which and C we are ignorant of, owing to the temperament of the inſtrument; this is the caſe with Dr. Smith's determinations (by the fifth and others of the methods above, Harmonics, p. 192, &c.) of the vibrations made by D *la-ſol re*, upon the organ above-mentioned.

We were lately preſent at an experiment by Mr. John Iſaac Hawkins, at his houſe in Great Titchfield-ſtreet, where he manufactures the finger keyed viols and double-baſſes, mentioned under our article CLAVIOL, (ſee FINGER-KEYED VIOL) according to our firſt method above: two pieces of hard wood, about an inch thick, were ſcrewed down to the floor in his room, at about 22 feet aſunder, and were pierced for the two ſtring-pegs of a harpſichord wire; ſeveral thin pieces of wood with a ſharp edge at top, and riſing a very ſmall height more above the floor, than the fixed pieces of wood, were provided as moveable bridges. A braſs wire, called No. 15, by the piano-forte makers, and the largeſt ſize which they uſe in grand piano-fortes, which was found to be .033 inch diameter, was lapped round the pins, and ſtretched by turning one of them. From a point marked 0 on the floor, 8 or 10 inches from one of the fixed pieces of wood, the ſeveral diſtances $7\frac{1}{2}$ inches, 15, 30, 60, 120, and 240 inches were carefully meaſured and marked under the ſtring; a bridge was then placed under the ſtring, at the point 0; another at $7\frac{1}{2}$, and another at 240 inches, and one of the tuning pegs was turned until the ſhort portion of the ſtring, 0 to $7\frac{1}{2}$, was in perfect uniſon with Mr. H's ſmall, or mouth tuning-fork, C; [which is a very conſiderable improvement upon the large tuning forks which require to be ſtruck upon a table, ſee TUNING-FORK] the bridge at $7\frac{1}{2}$ inches was then ſucceſſively moved to 15 and 30 inches, in order to compare the octave and double octave below with the fork, and which on trial appeared to be accurately in tune. This middle bridge was then removed, and the counting of the viſible vibrations of the whole ſtring, 0 to 240, or five octaves below C, was conducted as follows. Mr. H. kneeling down on one knee, placed a ſeconds watch before him, and held a quill with one hand ſlightly againſt the ſtring, about two feet from the bridge, ſo as to be ſtruck by the wire at each vibration; this was for aſſiſting the ſight, in counting the vibrations, by means of the audible ſtrokes thus produced on the quill: for ſome time. Mr. H. continued attentively to notice the vibrations, and to beat down with his toe at every fourth vibration, as a performer on the violin, &c. does in playing in common time; this was purſued, until ſuch a regular rate of beating was obtained by the toe that the experiment was not interrupted by a new twitch or impulſe given to the vibrating ſtring by an aſſiſtant; the counting then commenced, and was continued during 60 ſeconds, in the firſt of which 111 beats of the toe were made, and in a repetition of the experiment, after examining the time of the $\frac{1}{32}$ part of the ſtring, 113 beats were counted; the mean of theſe, or 112 per minute, gave $112 \times 4 \div 6 = 74\frac{2}{3}$ vibrations for the whole ſtring in 10 ſeconds, and conſequently C, five octaves above, gave $47\frac{2}{3} \times 32 = 2386$ vibrations in 10″, which agrees extremely near with Dr. Robiſon's experiments above mentioned, in ſhewing, that 2400 may be taken as the preſent concert-pitch.

We have only to add, that an experiment and calculation ſome years ago by the fifth method above, gave us 2415 pulſes in 10″ for a tuning-fork then in our poſſeſſion, marked C, but whether the ſame had been adjuſted to the acknowledged concert-pitch, we are unable to ſay. The ſtate of the barometer and thermometer ſhould always be noted, at the time of making experiments of this kind, if it is intended accurately to determine the pitch: and it may be well, inſtead of truſting to the ear alone, in determining the uniſon or octave of the fork and ſtring, to count and equalize their *beats* with a third ſound, a little different from both of them, as recommended by Mr. Nicholſon, Phil. Journ. 8vo. i. p. 320, for the making of correct tuning-forks.

CONCERT *of Ancient Muſic.* This excellent eſtabliſhment was originally ſuggeſted by the late earl of Sandwich in 1776, in favour of ſuch ſolid and valuable productions of old maſters as an intemperate rage for novelty had too ſoon laid aſide as ſuperannuated, was ſupported with ſpirit and dignity, by the concurrent zeal and activity of other noblemen and gentlemen of the firſt rank, who united with his lordſhip in the undertaking, till 1785, when it was honoured with the preſence of their majeſties, whoſe conſtant attendance ever ſince has given to this inſtitution an elevation and ſplendor, which perhaps no eſtabliſhment of this kind ever enjoyed before. Here the productions of venerable old maſters, particularly thoſe of Purcell and Handel, are performed by a ſelect and powerful band, with ſuch correctneſs and energy, as the authors themſelves never had the happineſs to hear.

CONCERT, *To*, in a *Military Senſe*, is not only to deliberate upon, but to arrange, form, and agree upon plans of co-operation, for the purpoſes of either offence or defence.

CONCERTANTE, Ital. from *cancertare*, to concert, order, arrange. In the muſical technica, it uſed to be equivalent to harmonizing, adding inſtrumental parts to vocal. But at preſent, the term concertante is uſed ſubſtantively, for a ſymphony or full piece dialogued. In which there are ſolo parts for the diſplay of great talents on particular inſtruments. At the concerts of Bach and Abel, ſolo parts were frequently allotted in theſe compoſitions to Cramer, Fiſcher, the younger Stamitz, Hindmarſh, Shields, Holmes, Tacit, and the elder Florio, Abel, on the viol di gamba, and Bach himſelf on the piano-forte. Bach's concertante in C♮, and Pleyel's in E♭, were always heard with rapture; not only from the merit of the compoſition, but exquiſite manner in which they were performed, and the ingenuity of the written cadences, generally furniſhed by Fiſcher.

CONCERTATO, a term in *Muſic*, implying the addition of inſtrumental parts to a vocal compoſition; as *motetto concertato*, a motet or anthem, accompanied by inſtruments.

CONCERTO, ſynonymous with *concento*, which long ſupplied its place. Concento and ſuono implied nearly the ſame things in the days of Boccaccio, as concerto and ſonata ſince; but concertare and concertanti were at firſt applied to the union of inſtruments with voices, in motets and madrigals, by doubling the voice-parts. It was not till late in the ſeventeenth century, that inſtrumental pieces of many parts, began to be called concertos, and of few parts ſonatas.

The earlieſt compoſitions which we found in Italy, for three or more inſtruments of the ſame ſpecies, were Ricercari and Fantaſie. But of theſe none ſeem to have been printed, when the elder Doni publiſhed the ſecond edition of his "Libreria," 1557, as all the inſtrumental muſic that appears in his catalogue of muſical compoſitions, which had then been publiſhed in Italy, are "Intabolature da organi, et da leuto, d'Anton da Bologna, di Giulio da Modena, di Franceſco di Milano, di Jaches Buas, piu di dieci volumi, e la continua."

About the beginning of the ſeventeenth century madrigals, which were almoſt the only compoſitions in parts for the chamber, then cultivated, ſeem to have been ſuddenly ſupplanted in the favour of lovers of muſic by a paſſion for fantaſias of three, four, five, and ſix parts, wholly compoſed for viols, and other inſtruments, without vocal aſſiſtance. And this paſſion ſeems to have ariſen, from the calling in theſe inſtruments to reinforce the voice parts, with which they played in uniſon, in the performance of motets and madrigals, thence termed *concertati*. At length the inſtrumental performers diſcovered that both the poetry and ſinging of the times might be ſpared without any great loſs or injury to muſical effects; as the words, if good, were rendered unintelligible by fugue, imitation, and multiplicity of parts; and the ſinging, being often coarſe and out of tune, could be better ſupplied by their own performance. Thus vocal muſic not only loſt its independence, but was almoſt totally driven out of ſociety; as the ancient Britons, calling in the Saxons to aſſiſt them in their conflicts with the Picts, were themſelves ſubdued and forced from their poſſeſſions, by too powerful auxiliaries. See FANCIES and BASE-VIOLS.

Simpſon in his "Compendium," ſpeaking of fancies, page 118, ſays: "In my opinion, no nation is equal to the Engliſh in this way, as well for their excellence, as for their various and numerous conſorts of 3, 4, 5, and 6 parts, made properly for inſtruments, of which fancies are the chief."

In the MS. "Memoirs of Muſic," by the hon. Roger North, who ſpeaking of Jenkins, an eminent Engliſh compoſer in the time of Charles I. ſays, that "of all his concerts, none flew about with his name to it, ſo univerſally, as the ſmall piece called his "Five Bell Conſorte." And this is only in three parts, ſo that the import of the term concert or conſorte was not then ſettled.

Montaigne, who travelled through Italy and Germany in 1580, ſays that the maſs in great churches was accompanied by organs and violins. But though the word concerto occurs ſo early as the year 1587, in the "Trattenimenti" or "Divertimenti" of Scipion Bargagli, it was only applied to ſhort Fantaſie and Ricercari. Salmi concertati was often uſed when inſtruments were added to voices, in concerti eccleſiaſtici.

At the latter end of the 17th century moſt of Baſſani's, Corelli's and Torelli's violin muſic was compoſed for the church. The firſt and third ſet of Corelli's ſonatas, and his firſt eight concertos, we are certain were thus appropriated. Somis, Veracini, and Tartini, compoſed their own ſolo concertos, and performed them likewiſe in the ſeveral churches of Italy. And Pugnani uſed to accompany the "Meſſa Bolla," or Silent Maſs, at the chapel royal in Turin, with his violin ſolo concertos.

Concertos merely inſtrumental, for ſecular uſe, ſeem to have had no exiſtence before the time of Corelli. The honour of the invention has been aſſigned to Torelli, but from no good authority. Six concertos by Aleſſandro Scarlatti, manifeſtly, from the gravity of their ſtyle, compoſed for the church, were printed by Benjamin Cook, in New-ſtreet, Covent-garden, about the year 1730. But at the beginning of the laſt century, beſides the concertos of Corelli, Geminiani, and Handel, concertos by Albinoni, Alberti, Teſſarini, and Vivaldi, were diſperſed all over the kingdom, and heard with great delight at our country concerts, muſic-meetings, and clubs. Theſe were chiefly on the model of Torelli and Corelli, but with melody of a lighter kind. They were all in ſeven or eight parts for two choirs; that is, with ſolo parts for the concertini, or ſolo inſtruments, and ripieno parts for the concerto groſſo, or chorus of the whole band. But theſe were ſoon ſuperſeded by great performers on the violin, ſuch as Locatelli, Tartini, Somis, Veracini, Nerla, and Giardini, who, in order to diſplay their ſuperior powers of execution, rendered them too difficult for general uſe. But theſe being brought into public favour by the admirable performance of their ſeveral authors, were followed by the concertos of Barthelemon, Cramer, La Motte, Lolli, Salomon, Viotti, Giornovichi, &c. who, by ſome peculiar excellence in the knowledge of the finger-board, uſe of the bow, or accurate performance of double-ſtops, ſeem to have arrived at the acme of perfection in executing ſolo concertos.

Concerto *Groſſo*, a grand concerto, or full piece.

Concerts, *public.* Theſe were firſt eſtabliſhed in London by Baniſter, maſter of king Charles II's new band of 24 violins. The firſt notice we find of theſe aſſemblies is in the London Gazette, No. 742, for Dec. 30th, 1672, in which there is the following advertiſement: "Theſe are to give notice, that at Mr John Baniſter's houſe, now called the muſic-ſchool, over againſt the George Taverne, in White Fryers, this preſent Monday, will be muſic performed by excellent maſters, beginning preciſely at four of the clock in the afternoon, and every afternoon for the future, preciſely at the ſame hour."

There are other advertiſements from Baniſter of the ſame kind, in 1674, 1676, and 1678. In that for Dec. 11th, 1676, his muſical performance is ſaid to be "At the academy in little Lincoln's-inn fields," where it was to begin "with the parley of inſtruments, compoſed by Mr. Baniſter, and performed by eminent maſters."

In Mr. North's manuſcript "Memoirs of Muſic," we have a more minute account of theſe performances. "Baniſter having procured a large room in White Fryars, near the Temple back-gate, and erected an elevated box or gallery for the muſicians, whoſe modeſty required curtains, the reſt of the room was filled with ſeats and ſmall tables, alehouſe faſhion. One ſhilling, which was the price of admiſſion, entitled the audience to call for what they pleaſed. There was very good muſic, for Baniſter found means to procure the beſt hands in London, and ſome voices to aſſiſt him. And there wanted no variety, for Baniſter, beſides playing on the violin, did wonders on the flageolet to a thorough baſe, and ſeveral other maſters likewiſe played ſolos."

Theſe were followed by other public concerts of a ſuperior kind, at the Crown and Anchor, the Caſtle in Paternoſter row, the Swan and King's Arms, Cornhill, York Buildings, Hickford's Room, &c. &c.

CONCESSI, q. d. *I have granted*; a term much uſed in conveyances, &c. Its effect is to create a covenant in law, as *dedi* (I have given) does a warranty. Co. Lit. 384. This word is of a general extent, and is ſaid to amount to a grant, feoffment, leaſe, and releaſe, &c. 2 Saund. 96.

CONCESSION, in *Rhetoric*, a figure whereby ſomething is granted or allowed to the adverſary, either to prevent being detained by unneceſſary incidents, or to make ſome advantage of. "I will not conteſt with you the reality of the contract; what I plead for, is relief againſt the injuſtice of it." "True, ſhe is fair; but ought ſhe not to ſhew her acknowledgments to heaven for the favour, by making a virtuous uſe of her beauty?" See Epitrope.

CONCESSIT, Sur, in *Law*, a ſpecies of *Fine*; which ſee.

CONCEVEIBA, in *Botany*, Lam. Encyc. Aubl. Guian. 924. tab. 353. Claſs and order, *diœcia*. Nat. Ord. *Euphorbiæ*; Lam.

Gen. Ch. *Male* flower not known. *Female. Cal.* one-leafed, fleſhy, trigonous near the bottom, with three large glands at its baſe, terminated by five thick acute teeth, each of which has on the inner ſide of its baſe a gland preſſing upon the germ. *Piſt.* Germ ſuperior, triangular; ſtyle none; ſtigmas three, thick, concave, furrowed, incurved. *Peric.* Capſule globular, trigonous, with three furrows, three-celled, three-valved, each valve dividing into two. *Seeds*, one in each cell, roundiſh, inveloped in a white pulpy matter which has a ſweet pleaſant taſte.

Sp. C. *guianenſis*. A ſmall tree. *Trunk* ten or twelve feet high, about a foot in diameter, with grey bark and white wood, much branched. *Leaves* alternate, at unequal diſtances from each other, oval-oblong, acuminate, toothed, green and ſmooth on their upper ſurface, cinereous underneath. *Stipules* in pairs, ſmall, caducous. *Flowers* ſeſſile, alternate, in a terminal ſpike, common peduncle fleſhy, trigonous. A native of Guiana, on the banks of rivers. When the bark is cut, or the leaves torn, a greeniſh juice iſſues from the wound.

CONCEZE, in *Geography*, a town of France; in the department of the Correze, and diſtrict of Brive; 6 leagues N.W. of Brive.

CONCH, in *Mythology*. See Triton.

CONCHA *Auris*, in *Anatomy*, is the large hollow of the external ear, included between the tragus, antitragus, and anthelix, and having at its anterior part the commencement of the meatus auditorius externus. See Ear.

Concha, Χογχη, in *Antiquity*, a liquid meaſure among the Athenians, which contained two *myſtra*, or half an ounce. As much oil as it was capable of holding, weighed five drams one ſcruple and twenty grains, according to Gor. Defin. Pitiſci Lex. & Eiſenchom. Others think that the *concha* contained three ſpoonfuls, ninety-ſix of which filled a pint veſſel (*ſextarius*;); a *ſextarius* was therefore equivalent to thirty-two *conchæ*, and ſix *ſextarii* made one *congius*, a meaſure equivalent to our three quarts, according to Salmaſ. Exerc. Plinian. and Bodæus in Theophraſt. According to Fernelius, the concha was equivalent to two *myſtra*, or five ſpoonfuls; which, according to Jacobus Sylvius, are equivalent to ſix drams. According to Galen, in his work De Ponderibus & Menſuris, cap. 11, the *concha magna* contained the ſame quantity with the *acetabulum*, which in liquid meaſure was an ounce and a half, and in weight fifteen drams. The *concha minor* was in liquid meaſure half an ounce, and in weight five drams.

Concha, in *Conchology*. See Conchology.

Concha, in *Muſic*, a trumpet among ancient inſtruments, or a trump-marine, ſuch as Triton uſed;

—— Tritona vocat; conchæque ſonaci
Inſpirare jubet.
Ov. Met. 1.

Concha *anatifera*. See Anatifera.

Concha *anomia*, the name of a foſſil ſhell-fiſh, found in great abundance, and in a great variety of ſpecies, but not known in any of them living, on the ſhores or in the ſeas of our own or other countries. In Glouceſterſhire, and ſome other of our counties, theſe are found as common as pebbles on the ploughed lands in other places. They are a ſort of bivalve ſhell, the valves of which are of unequal extent, both of them convex, and the head or beak of the longer valve crooked, and falling over the head of the other.

The great general diſtinction of this numerous claſs of bodies, is into thoſe which are of a ſmooth ſurface, and thoſe which are of a ſtriated or rough one.

Others alſo of the ſame claſs, or of one very nearly allied to it, are found in many of our inland counties, ſome very long from the cardo, or hinge, to the margin; and others very ſhort, and very long the contrary way. They are found indifferently in all ſorts of ſtrata, in earth, in ſtone, in ſand, and among gravel. See Anomia.

Concha *fortificata*, a name given by ſome authors to the genus of ſhells, called by others the Murex.

Concha *globoſa*, the name of a large genus of ſhells, called by authors the Dolium, and in French the *tonne*.

CONCHÆ Lapideæ, was the name by which ſome writers diſtinguiſhed the foſſil ſhells found lodged in the ſtrata of the earth, before the whims of certain authors reſpecting the *vis plaſtica, vis formativa,* &c., by which they attempted to account for the formation of theſe organic remains, had been entirely exploded, and the truth of their being animal exuviæ generally eſtabliſhed.

Concha *margaritifera,* a name ſometimes uſed for thoſe *mytuli* which produce pearls. See Muscle.

Concha *margaritifera,* is the name by which ſome writers have deſcribed a foſſil ſhell, ſomewhat reſembling the recent ſhells of this genus, in the equality of their valves, the appearance of their guttered and toothleſs hinges, &c.

Conchæ *narium,* in *Anatomy,* is a term applied to the turbinated bones of the noſe. See Skeleton.

CONCHA *ſpectrorum,* in *Natural Hiſtory,* the *ſpectre ſhell,* a name given by authors to a ſpecies of voluta, from ſome odd figures deſcribed on its ſurface, repreſenting rough draughts of terrible phantoms. It is an elegant ſhell, of a middle ſize, and is of a white ground, and the figures are reddiſh; theſe form three large and broad bands, ſurrounding the ſhell at top and bottom, and in the middle; and between theſe there are ſeveral ſeries of ſmall ſpots. It is a ſcarce ſhell, and uſually ſells at a large price.

Concha *Veneris,* the name by which ſeveral ſpecies of chama are called. The ſhell is univalve, wreathed, and has a ſmall longitudinal and denticulated chink, or aperture, in it. It is alſo called *concha porcellana,* from its aperture in ſome meaſure reſembling the mouth of a hog; and *concha erythræa,* from its being found in the Red Sea, called *erythræum.* It is alſo called *concha cytheriaca,* from Venus, who received the epithet *cytheræa,* from Cythera, a Grecian iſland. That this fiſh was uſed by the ancients as an aliment, we read in Seneca, Ep. 95. Mundius aſſerts that they prove a ſtimulus to venery, and provoke urine. Rondeletius informs us, that theſe ſhells are an ingredient in the *pilulæ de bdellio,* for removing fluxes, and curing ulcers in the uterus. But inſtead of the *concha venerea,* the apothecaries generally uſe cockles. Excellent dentrifices are prepared from this ſhell, which is alſo uſed for curing ulcers in the canthus of the eye, and the *fiſtula lachrymalis.* It is remarkably drying, without exciting any heat.

CONCHARUM Promontorium, in *Ancient Geography,* a promontory of Aſia Minor, on the Thracian Boſphorus, in the ſouthern part of the Caſtacian gulf.

CONCHES, in *Geography,* a town of France, in the department of Eure, and chief place of a canton in the diſtrict of Evreux, 12 miles S. E. from Evreux, 39 S. from Roüen, and 87 N. E. from Paris. The place contains 2259, and the canton 13050 inhabitants. The territory includes 257½ kiliometres, and 33 communes.

Conches, a town of France, in the department of the lower Pyrenées, and diſtrict of Pau; 6 leagues N.N.E. of Pau.

CONCHITES, or Conchitæ, in *Natural Hiſtory,* a name which has been indifferently uſed by writers, in deſcribing foſſil bivalve ſhells of different kinds.

Conchites *marmor,* a name given by the ancients to a ſpecies of marble dug near Megara, and remarkable for containing a great number of ſea-ſhells, and other marine bodies immerſed in it.

CONCHIUM, in *Botany,* from κόγχη, a bivalve ſhell, in alluſion to the form of the fruit. Smith, Tr. of Linn. Soc. v. 4. 215. Donn. Cant. ed. 3. 21. Vent. Jard. de la Malmaiſon, 110. (Hakea; Schrad. Sert. 27. Cavan. Jc. v. 6. 24.) Muſcle-ſhrub. Claſs and order, *tetrandria monogynia.* Nat. Ord. *Proteæ,* Juſſ.

Gen. Ch. *Cal.* none. *Cor.* of four petals, linear, cohering at their baſe, ſomewhat dilated and concave at the ſummits, nearly equal. *Stam.* four; filaments ſhort, inſerted towards the ſummit of each petal: anthers lodged in the cavity of each petal, erect, oblong, two-celled. *Piſt.* Germen ſuperior, ſmall, ovate, oblique: ſtyle aſcending, recurved, cylindrical, thick, as long as the corolla; ſtigma turbinate, pointed. *Peric.* Capſule ovate, oblique, gibbous and rugged, pointed, of two hard, thick, woody valves, and one ſmall eccentric cell. *Seeds* two, elliptical, flat on one ſide, convex on the other, filling the cavity of the capſule, each furniſhed with a black, membranous, tranſparent, oblong wing.

Eſſ. Ch. *Calyx* none. *Petals* four, bearing the ſtamens. *Stigma* turbinate, pointed. *Capſule,* of one cell. *Seeds* two, winged.

Sp. 1. C. *gibboſum.* Donn. Cant. 21. (Bankſia gibboſa; White Voy. 224. t. 22. f. 2. Willden. Sp. Pl. v. 1. 536. Hakea gibboſa; Cavan. Ic. t. 534. H. pubeſcens; Schrad. Sert. 27.) "Leaves cylindrical, ſlightly downy, rather longer than the fruit. Corolla ſmooth. Capſules roundiſh-ovate, gibbous, rugged." Sm MSS. *Stem* ſhrubby, branched, rigid, ſmooth. Young branches hairy. *Leaves* numerous, evergreen, alternate, ſeſſile, ſpreading, cylindrical, near two inches long, ſomewhat downy, eſpecially when young, each tipped with a ſharp ſpine. *Flowers* in ſmall, axillary, hairy umbels, white. *Corolla* nearly or quite ſmooth. *Capſules* ſolitary, the ſize of a walnut, black and rugged, very gibbous underneath; the valves extremely thick, hard and woody, each tipped with a ſhort ſharp point; cavity very ſmall, eccentric, uneven, of a mahogany colour. *Seeds* with black wings like gauze or crape. A native of New South Wales, near Port-Jackſon. It is now frequent in the more curious European green-houſes, but is rather ſingular than beautiful. 2. C. *ſphæroideum.* "Leaves cylindrical, as long as the fruit, downy as well as the branches. Capſules orbicular, depreſſed, ſmoothiſh." Sm. MSS. A ſmaller ſhrub than the laſt. *Branches* clothed with denſe woolly hairs. *Leaves* about an inch long, very hairy. *Flowers* unknown in Europe. *Capſules* of a ruſty brown, the ſize of the laſt, but much leſs rugged, and when viewed vertically, almoſt orbicular, their points ſcarcely extending beyond the circumference. Sent from Port-Jackſon with the preceding. 3. C. *aciculare.* Donn. Cant. 21. Vent. Jard. de la Malm. t. 111. (Hakea ſericea; Schrad. Sert. 27?) "Leaves cylindrical, ſmooth, as long as the fruit. Corolla ſmooth. Capſules roundiſh-ovate, rugged, elongated at the point." Sm. MSS. Like C. gibboſum, but in all its parts about half as large. *Leaves* in every period of their growth quite ſmooth. *Flower-ſtalks* and young branches ſilky. *Fruit* more oblong than in the two preceding, but its lateral protuberances are more globoſe. A native of Port-Jackſon, not rare in our gardens. 4. C. *longifolium.* Donn. Cant. 21. (Bankſia teretifolia; Saliſb. Prod. 51?) "Leaves cylindrical, ſmooth, thrice as long as the fruit. Corolla clothed with ſilky hairs." Sm. MSS. *Leaves* three inches or more in length, ſpinous, as in all the foregoing, always ſmooth, as well as the branches. *Corolla* clothed with white, cloſe, ſilky hairs. Perhaps only a variety of C. *pugioniforme* hereafter deſcribed, which cannot be determined till the fruit of the preſent ſpecies be known. 5. C. *compreſſum.* "Leaves cylindrical, ſmooth, ſcarcely ſo long as the fruit. Capſules ovate, compreſſed, ſomewhat rugged." Sm. MSS. The fruit of this is not more than an inch long, and ovate, partaking but little of the globular protuberant figure of the preceding kinds. *Leaves* ſmall and ſlender. 6. C. *pugioniforme.* (Hakea pugioniformis; Cavan. Ic. v. 6. 24. t.

533. H. glabra. Schrad. Sert. 27. t. 17.) "Leaves cylindrical, ſmooth. Corolla clothed with ſilky hairs. Capſules lanceolate, pointed, beſet with ſharp tubercles towards the baſe." Sm. MSS. *Leaves* an inch or inch and a half long, bright green, always ſmooth, as well as the branches. *Flowers* white and ſilky. *Capſules* very different from the reſt of the genus, being much more ſlender. This, like all the preceding, is found in the country about Port-Jackſon, New South Wales. 7. C. *trifurcatum.* "Leaves cylindrical, three-cleft; ſometimes dilated, ſimple, elliptical and flat. Corolla hairy." Sm. MSS. This moſt remarkable ſpecies, diſcovered by Mr. Archibald Menzies, F.L.S. at King George's Sound, on the weſt coaſt of New Holland, is diſtinguiſhed by its three-forked leaves, but eſpecially by their occaſional variation from a cylindrical to a broad flat elliptical figure, on the ſame branch, and even in the ſame individual leaf. The *flowers* and their ſtalks are clothed with rough, ſhaggy, not ſilky, hairs. *Fruit* unknown. 8. C. *dactyloides.* Vent. Jard. de la Malm. t. 112. (C. nervoſum; Donn. Cant. 21. Hakea dactyloides; Cavan. Ic. v. 6. 25. t. 535. Bankſia dactyloides; Gærtn. v. 1. 221. t. 47. f. 2. B. oleæfolia; Saliſb. Prod. 51.) "Leaves obovate-oblong, with a ſmall point, triply nerved, veiny. Capſules ovate, acute." Sm. MSS. *Leaves* various in length and breadth, flat, thick, rigid, ſmooth, entire, obovate, tapering towards the baſe, marked with three principal nerves united above the baſe, and connected upwards by interbranching veins, forming ſometimes ſpurious nerves. The young leaves and branches are ruſty and downy. *Flowers* numerous, ſmall, white, ſmooth, on hairy ſtalks. *Capſule* ovate, acute, rugged, ſcarcely gibbous. Common about Port-Jackſon, and not rare in our gardens, where the varieties to which it is ſubject in the leaves, afford the nurſerymen an opportunity of furniſhing their friends with many new ſpecies. 9. C. *ellipticum.* "Leaves elliptical, bluntiſh, pointleſs, with five nerves, reticulated with veins. Capſules ovate, obtuſe." Sm. MSS. Allied to the laſt, but diſtinct. *Leaves* broad, exactly elliptical, ſomewhat glaucous, having five ribs, which all ſpring from the baſe, and deſtitute of any terminal point or ſpine. The ſpaces between the ribs or nerves are beautifully and copiouſly reticulated. *Capſule* more obtuſe than in C. *dactyloides*, but otherwiſe much like it. Found by Mr. Menzies at King George's Sound, but not yet brought alive to Europe. *Flowers* not ſeen. 10. C. *oleifolium.* "Leaves elliptic-lanceolate, with a ſmall point, ſingle-nerved. Capſules ovate, gibbous, ſomewhat rugged." Sm. MSS. Brought by Mr. Menzies from the ſame country as the laſt. Full-grown *leaves*, ſcarcely an inch and half long, ſmooth, even and entire, with only one rib, tipped with a little ſpine. Veins few and obſcure. *Flowers* ſpiked, ſmooth, as well as their partial ſtalks, though the common ones are hairy. *Capſule* ovate, gibbous on one ſide, very rugged all over. 11. C. *ceratophyllum.* "Leaves three-lobed, pinnatifid. Capſules ovate, compreſſed." Sm. MSS. *Leaves* very fine, large and divaricated, from two to four inches long, ſmooth, except when very young, hard and rigid, obſcurely ribbed, lobes and teeth ſpinous. *Flowers* ſilky. *Capſule* narrow, ovate, compreſſed, ſmooth, apparently ſucculent in its outer coat, which ſeems to be the caſe with the three preceding ſpecies. Gathered at King George's Sound, by Mr. Menzies. It is one of the handſomeſt of its genus. 12. C. *ſalignum.* Donn. Cant. 21. (Embothrium ſalignum. Andr. Repoſ. t. 215.) "Leaves linear-lanceolate, acute, without ſpines, ſingle-nerved. Capſules ovate, gibbous, recurved." Sm. MSS. A tall elegant ſhrub, with the habit of a willow. *Leaves* five or ſix inches long, ſmooth and pliable, of a narrow lanceolate form, entire, acute, but not ſpinous, with one nerve and a few lateral veins. *Flowers* copious, white, ſmooth, in ſmooth umbels, which, as in all the reſt of the genus, are axillary. *Capſule* ſmalliſh, ovate, recurved, very gibbous, and ſomewhat rugged, at each ſide, tapering at the baſe, externally hard and not ſucculent, each of its valves tipped with a lateral ſpine. A native of New South Wales, frequent in gardens.

Propagation and Culture. All the ſpecies are ſhrubby and perennial, eaſily raiſed from ſeeds brought in the capſules from their native country, and requiring with us only the uſual ſhelter of a green-houſe or conſervatory. Thoſe from King George's Sound are as yet ſtrangers to our gardens. The others thrive in ſandy peat earth, but require regular and rather copious ſupplies of water. They may be increaſed by cuttings. C. *ſalignum* ripens ſeeds in abundance when planted in the ground under glaſs, and riſes to the height of 12 or 15 feet. S.

CONCHOID, or CONCHILIS, in *Geometry*, a curve line which always approaches nearer a ſtraight line to which it is inclined, but never meets it. It was invented by Nicomedes, and much uſed by the ancients, as we learn from Pappus, in the conſtruction of ſolid problems.

It is deſcribed thus: draw a right line B D (*Plate, Analyſis, fig.* 2.) and another A C, perpendicular to it in E; draw any number of right lines, as C M, C M, cutting B D in Q; make $QM = QN = AE = EF$: the curve wherein the points, M, M, are found, is the *conchilis*, or *conchois prima*, ſo called by Nicomedes. The other, wherein the points, N, N, are found, is the *conchois ſecunda*; the right line B D the *rule*, or *directrix*, the point C the *pole*, or centre of the conchoid. In reality, they are both parts of the ſame curve, having the ſame pole C, and four infinite legs, to which the line B D is a common aſymptote. The inventor alſo contrived an inſtrument, whereby the firſt conchoid may be deſcribed mechanically: thus, in the rule A D (*fig.* 3.) is a channel or groove cut, ſo that a ſmooth nail, firmly fixed in the moveable rule C B, in the point F, may ſlide freely within it: into the rule E G is fixed another nail in K, for the moveable rule C B to ſlide upon. If then the rule B C be ſo moved, as that the nail F paſſes along the canal A D; the ſtyle, or point in C, will deſcribe the firſt conchoid.

Now let $AP = x$ (*fig.* 2.); $AE = a$; $PE = MR = a - x$; wherefore, as x increaſes, $a - x$, or M R will decreaſe; and therefore the curve continually approaches nearer to the rule B D.

In the ſame manner it appears, that the right line N O muſt continually decreaſe; and therefore that the ſecond conchoid, alſo, muſt continually approach nearer the rule.

But inaſmuch as between each conchoid and the right line B D, there will be the right line Q M or Q N, equal to A E; neither of the conchoids can concur with the right line B D: conſequently B D is an aſymptote of each conchoid. See ASYMPTOTE.

If from any point, A, of the curve (*fig.* 4.), A H and F T P be drawn perpendicular to the rule, or directrix, H T, and A L parallel to it; and if the quadrant, F G K, be deſcribed interſecting A L in G; we ſhall have $PL \times LG = TL \times LA$. For the triangles, A H B, T L G, are ſimilar and equal, as the angles at H and L are right; and $AB = TF = TG$, and $AH = TL$; therefore $BH = GL$. Alſo the triangles, A H B, A L P, are ſimilar. Whence $AH : HB :: PL : AL$; that is, $TL : GL :: PL : AL$; therefore, $PL \times GL = TL \times AL$. Hence, the ſame things being ſuppoſed, we ſhall have $AG = BT$, and $GL = HB$. For $AL = HT$, and $GL = HB$.

$= HB$; therefore, by ſubtraction, we ſhall have $AG = BT$. This propoſition is equally true in the inferior conchoid *(fig. 5.)*. In the inferior conchoid $gl = bh$. Moreover, in the ſuperior conchoid *(fig. 4.)*, if PTF and AH be perpendicular to the directrix HT, and AL parallel to it, $TL^2 : TF^2 - AH^2 :: PL^2 : AL^2$. For, by the preceding propoſition, $TL : GL :: PL : AL$, and $TL^2 : GL^2 :: PL^2 : AL^2$; but $GL^2 = GT^2 - TL^2 = TF^2 - AH^2$; therefore $TL^2 : TF^2 - AH^2 :: PL^2 : AL^2$.

Hence, putting $FT = a$, $PT = b$, axis $TH = x$, ordinate $HA = y$; the equation of the ſuperior conchoid will be $\frac{\overline{b+y}\sqrt{aa-yy}}{y} = x = AL$, or, by reducing it, we ſhall have $\overline{b+y}\sqrt{a^2-y^2} = yx$, i. e. $\sqrt{\overline{b^2+2by+y^2}\times\overline{a^2-y^2}} = yx$, or $\sqrt{a^2b^2+2a^2by+a^2y^2-b^2y^2-2by^3-y^4} = yx$, and $a^2b^2+2a^2by+a^2y^2-b^2y^2-2by^3-y^4 = y^2x^2$; whence, by tranſpoſition, we ſhall have $y^4+2by^3+b^2y^2-a^2y^2+x^2y^2-2a^2by = a^2b^2$, i. e. $y^4+2by^3+\overline{b^2-a^2+x^2}\times y^2-2a^2by = a^2b^2$. Thus alſo, in the inferior conchoid *(fig. 5.)*, if pft and ah be perpendicular to the directrix ht, and al parallel to it; we ſhall have $tl^2 : tf^2 - ah^2 :: Pl^2 : al^2$. For $tl : gl :: Pl : al$; and $tl^2 : gl^2 :: Pl^2 : al^2$: but $gl^2 = bh^2 = ba^2 - ah^2 = tf^2 - ah^2$; therefore $tl^2 : tf^2 - ah^2 :: Pl^2 : al^2$.

Hence putting $tf = a$, $tP = b$, axis $th = x$, ordinate $ha = y$, the equation of the inferior conchoid will be $\frac{\overline{b-y}\sqrt{a^2-y^2}}{y} = x = al$. And, when reduced, $y^4 - 2by^3 + \overline{bb-a^2+x^2}\times y^2 + 2a^2by = a^2b^2$. Or, it may be had from the equation of the other curve by merely changing the ſign of y, which in this caſe is negative.

Of the whole conchoid, expreſſed by theſe two equations, or rather by one equation only, with different ſigns, there are three caſes or ſpecies; as firſt, when EF is leſs than EC, as in *fig.* 2; when EF is equal to EC, as in *fig.* 6; and when EF is greater than EC, as in *fig.* 7, in which latter caſe the conchoid is called *nodated*. The ſame equation holds for this nodated conchoid, the whole difference being merely that a is here greater than b.

Sir Iſaac Newton approves of the uſe of the conchoid for triſecting angles, or finding two mean proportionals, or for conſtructing other ſolid problems. To this purpoſe, he ſays, in the linear conſtruction of equations towards the cloſe of his "Univerſal Arithmetic:" "The ancients at firſt endeavoured in vain at the triſection of an angle, and the finding of two mean proportionals by a right line and a circle. Afterwards they began to conſider ſeveral other lines, as the conchoid, the ciſſoid, and the conic ſections, and by ſome of theſe to ſolve theſe problems." Again, "Either, therefore, the trochoid is not to be admitted at all into geometry, or elſe, in the conſtruction of problems, it is to be preferred to all lines of a more difficult deſcription; and there is the ſame reaſon for other curves; for which reaſon we approve of the triſecting of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the inventions of all others in this caſe; becauſe we ought either to exclude all lines, beſides the circle and right line, out of geometry, or admit them according to the ſimplicity of their deſcriptions, in which caſe the conchoid yields to none, except the circle." Laſtly, "that is *arithmetically* more ſimple which is determined by the more ſimple equations; but that is *geometrically* more ſimple which is determined by the more ſimple drawing of lines; and in geometry, that ought to be reckoned beſt, which is geometrically moſt ſimple; wherefore I ought not to be blamed, if, with that prince of mathematicians, Archimedes, and other ancients, I make uſe of the conchoid for the conſtruction of problems."

There will be other kinds of conchoids produced, if $CE : CQ :: QM : AE$; or indefinitely, if $CE^m : CQ^m :: QM^m : AE^m$: wherefore, if $CE = b$, $EA = a$, $CQ = x$, $QM = y$; then $ab = xy$; and for infinite conchoids, $a^m b^m = x^m y^m$.

CONCHOLOGY. "The ſtudy of ſhells, or teſtaceous animals," it has been well obſerved by a plain, but ingenious writer, "is a branch of natural hiſtory, though not greatly uſeful in human economy, yet perhaps by the infinite beauties of the ſubjects it treats of, is adapted to recreate the ſenſes, and inſenſibly lead the amazed admirer into the contemplation of the glory of the Divinity, in their creation." Or, in the more harmonious periods of the poet, we would ſay,

> "Each ſhell, each crawling inſect holds a rank
> Important, in the plan of him who framed
> This ſcale of beings;"———STILLINGFLEET.

Shells appear to form a part of the creation not immediately ſubſervient to the purpoſes of human life. This is granted; but they are a link in the great chain of nature; they conſtitute a department of rational inquiry worthy the reſearches of the man of ſcience; and when we conſider the amazing diverſity of ſingular and beautiful objects they embrace, are ſuch, we are perſuaded, as cannot fail to arreſt in a particular degree the regard of every common obſerver.

A late writer, whoſe talents we reſpect, aſſerts, in undiſguiſed terms, that the purſuits of the conchologiſt are frivolous, and tend to no uſeful purpoſe. For the credit of the philoſophical inquirer in this pleaſing department of natural knowledge, we could wiſh to ſee this opinion controverted. We ſhall not indeed endeavour to ſupport the pretenſions of conchology to a diſtinguiſhed rank among the more beneficial purſuits of ſcience, but we do not fear to prove it in a pre-eminent degree entitled to the attention of every contemplative mind. In the preſent enlightened period, it is not, we ſhould conceive, incumbent to offer any argument in its behalf, becauſe we are unable to prove its utility in the common acceptance of the term. We are not, for this reaſon alone, to eſteem it frivolous; or, in a word, to declare that our ideas are entirely abſorbed in the contemplation of intereſted views and the love of wealth, or that we are ſtudious only to gratify our immediate wants. Our untutored anceſtors cultivated the oak, we are told, that they might eat acorns, regardleſs of the importance of the parent timber; but we are not to imitate their example, and deem it trifling to cultivate any branch of natural ſcience, that is unlikely to afford us ſome direct benefit; nor are we to be content with aſcertaining what may be merely uſeful as food for ourſelves, or fodder for our cattle. How unworthy would this be of the refined conceptions and dignity of intellectual men? But we reſt convinced that a more enlarged and liberal idea of this ſubject will be conceived on the ſlighteſt reflection by every intelligent mind; that the ſcience of conchology will be hereafter more ſucceſsfully purſued in this country than it has hitherto been, and that the obſervations we have to offer as we proceed, though leſs abſtruſe than the ſcience may ſeem to demand, will to a certain extent facilitate this deſirable object.

One clear and moſt important fact, the truth of which we would wiſh to impreſs on the mind of the reader, ſhould be premiſed, that whatever opinion we may form on this ſubject,

ject, or however lightly we may be diſpoſed to appreciate its merits, the ſcience of conchology, or in more humble terms the ſtudy of ſhells, has in a greater or leſs degree attracted the attention of curious and contemplative minds throughout all ages; though, as may be naturally conceived, it has been cultivated with more ſucceſs in ſome periods than in others. The beauties of this part of the creation did not eſcape the obſervation of philoſophers in the firſt ages of learning, as appears obvious from the writings of Ariſtotle, of Pliny, and of Ælian, and we may alſo add of Athenæus and Cicero. The cultivation of this, like all other liberal ſtudies, was neglected in the darker æra that ſucceeded, or at leaſt no evidence to the contrary has ſurvived to this period; but in after ages, as the miſts of Gothic ignorance which had ſo long overhung the weſtern world diſperſed, and the light of ſcience, like the morning twilight, dawned upon the horizon of the human mind, conchology revived, was countenanced, encouraged, and flouriſhed. And if, in later times, it reſigned a precedence to other ſciences, in conformity to the example of the great Linnæus, who was perhaps leſs favourably inclined towards the ſtudy of ſhells than any other department of nature, it is pleaſing to add, that ſince his time this ſubject has been moſt aſſiduouſly cultivated, and that by writers no leſs eminently qualified to exalt its character than to give ſtability to the ſcience itſelf.

The term conchology comprehends the ſtudy of all animals which have a teſtaceous covering, whether inhabitants of the marine element, freſh water, or the land. Teſtaceology is a term ſynonymous with conchology, but is of later origin and application.

A preciſe diſtinction ſhould be drawn between teſtaceous and cruſtaceous animals; they are eſſentially different; though both are protected by a hard exterior ſhell or cruſt, in which they are partially or entirely enveloped; and have been indiſcriminately confounded together, for that reaſon, under the vague denomination of "ſhell-fiſh." Some of the old writers, and alſo Da Coſta, diſtinguiſh the teſtacea as a kind of ſtone-like calcareous covering or habitation, in which the animal, otherwiſe naked, reſides, and from which it can protrude its molluſcous arms, or other naked parts of its body, at pleaſure. The cruſtaceous animals of thoſe authors, on the contrary, are not naked, but have every particular limb or part ſeparately covered with the cruſt, which is thus divided into many joints, inſomuch that the whole animal aſſumes a loricated appearance, as if incloſed in a coat of mail. Among the cruſtaceous order, the *cancri*, or crabs and lobſters, were included, a tribe we have endeavoured to ſhew in another article, to be of a nature altogether diſtinct from teſtaceous animals. (See CANCER.) Klein, in his "Nat. Diſp. Echinodermatum," ſect. I. treats on this ſubject, and labours to prove that the echini, which are evidently cruſtaceous bodies, are of the ſame nature and quality as the teſtacea; but recent, and we think concluſive obſervations, teſtify the fallacy of his opinion. A better definition may be obtained by attending to the chemical properties of the two ſubſtances teſtaceous and cruſtaceous. Poli, in his work on the ſhells of the two Sicilies, demonſtrates that teſtaceous bodies conſiſt of calcareous earth united to a ſmall portion of animal matter or gluten; and Mr. Hatchett, whoſe experiments on the chemical characters of thoſe bodies are inſerted in the Tranſactions of the Royal Society, draws a ſtriking diſtinction from analyſis between the teſtaceous and cruſtaceous bodies, aſcertaining the firſt to conſiſt only of carbonate of lime mixed with gelatinous matter, while in the other the preſence of phoſphate of lime was detected. The cruſtaceous body analyſed by Mr. Hatchett was the echinus.

All teſtaceous animals are compoſed of two parts; one of which, the animal itſelf, is ſoft and molluſcous; the other is the ſhell, or habitation, which is hard, of a ſtony or calcareous nature, and either partially or entirely covers the animal. The animal is attached to the ſhell by means of ligaments or muſcles.

It was long conſidered as a matter of diſpute among naturaliſts, whether the arrangement of ſhells ſhould be conſtituted from the animals or their habitation. No one can deny, that if we proceed on principles ſtrictly ſcientific, we muſt regard them as a department of zoology, and ſhould, on that account, diſpoſe them according to the nature and ſtructure of the animals. But the claſſification formed from the characters of the ſhells is univerſally followed, and we muſt confeſs too, is for many reaſons preferable to any other. Neither is it, in the hands of the ſkilful conchologiſt, attended with ſo much indeciſion, as might be generally imagined.

In the firſt place among the vaſt variety of ſhells hitherto diſcovered, how ſmall comparatively is the number of thoſe, whoſe animal inhabitant is deſcribed or known. It is not of ſpecies only that we ſpeak, but of whole natural families or genera, not a ſingle ſpecies of which has been yet diſcovered with the animal appertaining, ſo little are we acquainted with the molluſcous orders, or animals inhabiting the ſhells. Of the ſhells we daily ſee in collections few are fiſhed up alive, the far greater number are found on ſhores, dead or empty. Neither, if it were otherwiſe, are accurate deſcriptions of animals whoſe parts are not eaſily ſeen, or anatomical inveſtigations, which are in many caſes neceſſary, within the capacity of every one. Many of their parts, and their reſpective functions, are not to be aſcertained, except by comparative analogy, and which in itſelf preſents an inſurmountable difficulty, or a field of critical inquiry ſo extenſive and complicated that few, even with the ability to purſue it with ſucceſs, could be prevailed upon to devote that attention to the ſubject which it requires.

Hence it becomes impoſſible to arrange the far greater number of teſtaceous productions by the animals; the attempt muſt ever prove unſucceſsful. Our arrangements would be partial, and three-fourths of the ſhells known muſt be either excluded from the ſyſtem, or be placed at hazard; and of courſe without order or connection with thoſe whoſe animals we are acquainted with. The latter are chiefly ſuch as are confined to the coaſts of the European ſeas, and ſome of the terreſtrial and freſh water kinds, which, from their abundance and locality, have obtruded themſelves upon the inveſtigations of the naturaliſt. Even our knowledge of thoſe is exceedingly imperfect. For thoſe of the extra European ſpecies, we are indebted chiefly to Adanſon, Rumphius, Argenville, and Favanné, and for the anatomical diſcuſſions on various European kinds to Valentini, De Heide, Liſter, and Müller. The inveſtigations of Poli on the ſhells of the two Sicilies are valuable, in this reſpect, as alſo are the obſervations of Lamarck, and Cuvier, and we may alſo add Olivier; but what is the amount of all theſe diſcoveries, we would aſk, in enabling us to form a ſyſtem of conchology.

The beſt characters upon which to found all ſyſtems of natural hiſtory, muſt be thoſe moſt obvious and acceſſible. All ranks of animals, as nearly as can be with convenience, ſhould be arranged by apparent and external characters. While we ſtudy ſhells, without regarding the animal, we are aware they are but conſidered partially. The animals that inhabit them ſhould guide us in our reſearches; they alone are the fabricators of the ſhell, and the ſhell is only their habitation, to which they give the form, the bulk, hardneſs, colours, and all the peculiarities of elegance we admire. If we were to examine theſe new and almoſt unknown beings, we ſhould diſcover a number of parts as remarkable for their ſtructure as their functions, and an infinite variety of curious and intereſting particulars relative to their general habits and manners of life. It is a ſubject worthy of the ſerious contemplation and attention of the naturaliſt, and ſhould never be neglected when an opportunity offers. But a ſyſtem of conchology, founded entirely on the ſtructure of the animals, muſt, we cannot heſitate in aſſerting, ever remain one of the deſiderata of natural ſcience.

In the ſuperficial arrangement taken from ſhells alone we are not exempt from difficulty. Shells vary exceedingly in form and colour in the different ſtages of their growth, and in this caſe we ſhould ſometimes derive material aſſiſtance from our knowledge of the animal. Young ſhells have been deſcribed as ſpecifically diſtinct from the parent or older ſhells by many writers. It indeed requires a greater degree of caution in determining the ſpecies, nay even genera, of ſhells in the different periods of growth than may be imagined; of this we could adduce many very remarkable inſtances, a few it may be neceſſary to mention to guard the common obſerver from forming haſty, and erroneous concluſions.

Many of the cyprææ, or cowries, when young, have the appearance of a volute, the thick denticulated fold of the exterior lip being wholly wanting, and the column being only partially plaited as in the true voluta. The young of the alated ſhells, in general, are deſtitute of that broad expanſive, or furcated lip, called the wing. The ſpires in many of the turrited kinds of ſhells, when young, are blunt; obtuſe, or terminated in a large globular head, exceeding the ſize of the whorl beneath, but as the ſhell advances in growth, it developes itſelf, extending in a ſpiral direction, and thus in the old ſhells the number of ſpires is greater than in the young ones. The variations in the growth of the patella tribe are often ſo conſiderable, as to almoſt defy the critical obſerver to determine them. Still however the conchologiſt by the dint of application, and nice diſcrimination, will be at laſt enabled to fix on certain characters peculiar to every ſpecies, and be, by that means, enabled to decide on the ſpecies of a ſhell under every ſtage of growth.

Linnæus conſiders the ſtructure of the animal as well as the ſhell in all his generical diſtinctions; the idea is excellent, and we ſhould approve the deſign, but the object itſelf is unattainable; a lamentable proof of which preſents itſelf to view, when we conſider the number of thoſe very animals which he deſcribes that have been aſcertained, by recent obſervations, to be of a very different nature and ſtructure from what he conceived. This error may be eaſily accounted for when we reflect that the judgment of Linnæus was guided in many inſtances by analogy, and the indifferent figures extant in various writers, without himſelf poſſeſſing the means of determining their accuracy, or imperfection. We intend nothing to the diſparagement of Linnæus in this reſpect; the ſtructure of the animal was of too much importance in his mind to be omitted, and he availed himſelf of the beſt ſources of authority within his power, ſome of which, it has ſince been proved, are not ſo accurate as we could wiſh, and others altogether erroneous.

From all that has been advanced on this topic, the reſult will be obvious, that teſtaceous bodies may be conſiſtently arranged, or, in other words, can only be arranged by the organization of the ſhell; that the primary character muſt be taken from the ſhell becauſe this we are acquainted with, while the animal is oftentimes unknown to us. But that the ſtructure of the animal ſhould be regarded in the conſtruction of genera, when it can be aſcertained; as a ſecondary conſideration to guide us in the formation of new genera, or in correcting the old, as opportunities of inveſtigating them occur.

Having defined the meaning of a teſtaceous animal, and endeavoured to prove that the ſtructure of the ſhell is the moſt material object to be regarded in a primary view, we ſhall proceed next to an elementary elucidation of the ſeveral parts of which it is compoſed.

In conchology, as in any other ſcience, the ſtudent muſt neceſſarily acquire, in the firſt inſtance, a diſtinct knowledge of the terms employed. Theſe, except ſuch as relate to ſubordinate characters, or ſpecifical diſtinctions, and which require no explanation in this place, may be ſimplified and reduced to a ſmall number. In the ſelection of theſe terms we can abide by no one particular authority; we muſt be general, deriving our terms from various ſources, or inventing new ones. Hitherto in treating on the different articles of conchology, in the progreſs of this work, it has been our aim to adhere as nearly to the authority of Linnæus as poſſible, reſerving to ourſelves an opportunity of expreſſing our own ſentiments under the preſent article, and ſtating generally theſe points upon which we principally differ in opinion from that author. This will appear more fully in our review of his genera. Our attention is at this time confined to the terms employed in deſcribing the ſeveral parts of ſhells, and as it is well known that Linnæus laid down a ſeries of terms for this purpoſe, it will be expected that we ſhould not paſs over them in ſilence. Upon this ſubject we ſhall however only treſpaſs lightly. We would willingly adopt thoſe eſtabliſhed by Linnæus, in his "Fundamenta Teſtaceologiæ," and other writings; but it muſt be confeſſed, with all our reſpect for the talents of that naturaliſt, his terms are inadmiſſible. The warmeſt of his admirers, and we muſt, on many occaſions, profeſs ourſelves of that number, will not peruſe the definitions he has given of the bivalves, of his venus, and ſome other bivalve genera, of his venus dione, and alſo of ſeveral univalves, without admitting that much of the Linnæan phraſeology on this ſubject is neither applicable to the parts intended, nor if it were, ſuch as modeſty would allow us to retain; and that to expunge them is only a neceſſary ſacrifice which the chaſtity of ſcience imperiouſly demands. Delicacy will pardon the alluſion, and deſire no further explanation.

All ſhells or teſtaceous bodies hitherto diſcovered, may be divided into three principal tribes, and which, after the Linnæan manner, may be denominated Multivalve, Bivalve, and Univalve.

Any external part of a ſhell being of a teſtaceous ſubſtance, and either itſelf, forming a ſhield or covering for the animal, as in univalves, or in union with another, or others connected by a ligament, cartilage, hinge, teeth, or other faſtening, is denominated a valve. The ſhells therefore conſiſting of a ſingle piece, are called univalves, thoſe of two parts bivalves, and thoſe of many parts multivalves. Between bivalve and multivalve no diſtinction is drawn, ſhells conſiſting of more than two ſuch parts, being called multivalve, without any regard to the number. An amendment is propoſed by ſome of the French writers, in a new order under the name of trivalve.

Shells of the ſimpleſt form are arranged by ſome naturaliſts in the firſt claſs, from which they proceed progreſſively to thoſe poſſeſſing the greateſt number of valves, and being of the moſt intricate ſtructure. This is an ancient, and very ſimple mode of arrangement, and has its advocates in the preſent day. Linnæus reverſes this order by beginning with the chiton, lepas, and pholas, which are ſhells of the multivalve and moſt complex ſtructure, and ending with thoſe of the ſimpleſt form. We cannot avoid thinking the former preferable, and ſhall adopt it in the preſent inſtance.

Explanation of the Parts of Shells with Reference to the Elementary Plates of Conchology.

Univalve.

In the examination of a ſhell of this order, the contour, or outline, is the firſt particular to be regarded. By this the conchologiſt is guided in his definition of ſimple, ſpiral, or turbinated ſhells, (or as the Linnæan ſchool divides ſhells, univalves with a regular ſpire, and univalves without a regular ſpire); diſcoid, flattened, or turrited ſhells; thoſe with ſmooth or uneven *anfractus*; the ventricoſe, alated, labiated, roſtrated, and many other diſtinctions, all which ſtrike the eye at the firſt view. It is indeed, by attending to the contour, that the principal diſtinctions in ſhells of this kind are at once perceived, taking into conſideration the back and front profile at the ſame time. Some few ſhells, as the nautilus pompilius, and others of the ſame family, have the ſpire revolving internally, in which the outline offers leſs aſſiſtance in the primary definitions, but the number of ſuch ſhells is very ſmall. Next to the profile of the ſhell, the ſtructure of the mouth, the pillar, and expanſion of the inner lip, the gutter or canaliculation, and the umbilical opening, and operculum if any, are to be conſidered, and laſtly the work on the outer ſurface, as well as the colours with which it is embelliſhed.

The baſe or bottom of the ſhell we conſider that part upon which it reſts when ſupported in an erect poſition, with the ſummit or tip of the ſpire ſtanding vertically. In ſuch ſhells the tip is called the apex. The courſe of the ſpires or wreaths is from the left to right in moſt ſpiral ſhells, ſome few only being of the reverſed or heteroſtrophous kind, the whorls of which are in a contrary direction. When ſpeaking of the right and left ſides of a ſhell, it ſhould be underſtood as having the aperture downwards, and it will be then ſeen that in moſt ſhells the aperture or opening is on the left ſide, *i. e.* facing the right hand of the ſpectator.

Baſe, the tip of the ſalient end of the ſhell, at the extremity oppoſite the apex of the ſpire; in the roſtrated kind of univalves it implies the tip of the beak. Some ſay the ſhell reſts on its baſe when laid upon a flat ſurface, with the mouth downwards; this is not correct, except in the patella tribe, and ſome other univalves which have no regular ſpire, as the dentalium, &c. The baſe in ſeveral ſhells is denoted in the Plate, *Conchology*, *fig.* 1.

Apex, the ſummit of the ſhell. *Fig.* 2.

Front, the face of the ſhell with the aperture placed directly in front of the obſerver. *Fig.* 3.

Back, that part of the ſhell which is immediately oppoſed to the preceding. *Fig.* 4.

Sides, thoſe parts ſeen longitudinally in profile, to the right and left when the ſhell is viewed either in a front or back poſition. *Fig.* 5.

Body, of the ſhell, (corpus) the firſt whorl of the ſpire at the baſe. *Fig.* 6.

Belly, is to be diſtinguiſhed from the body as it implies only the convex or ſwollen part of the firſt whorl, formed by the convexity of the aperture near the lip. *Fig.* 7.

Whorl denotes one of the wreaths, turns, or volutions of the ſhell. *Fig.* 8.

Spire, comprehends, in a general ſenſe, all the whorls of the ſhell, the firſt or body wreath excepted. *Fig.* 9.

The form of the ſpire is of great conſideration in the definition of ſhells as it affords a prominent and diſtinguiſhed character; it is in general flattiſh, ſomewhat depreſſed or elevated; ſometimes convex and ſlightly pointed; or with the point obtuſe; or much elevated and ending in a point; plano-concave, pyramidal, ſubulate, or truncated. Mr. Adanſon obſerves that the diſpoſition of the ſpires varies according to the plane they turn on, which is either horizontal, cylindrical, conic, or ovoid. Theſe, he conceives to be the four principal diſpoſitions of the ſpires, but admits there are many intermediate formations. The number and form of the ſpires vary in the ſame ſpecies, in their different growths. Young ſhells have commonly a leſs number than the old ones, neither have ſhells of the ſame age always the like number of ſpires, a circumſtance attributable to the effects of ſickneſs, or the difference of ſex. Thus in ſome turbinated ſhells we perceive that the males have the ſpires leſs numerous, ſmaller, and of a more lengthened form than in the females.

Suture of the ſpire or whorls, is the ſpiral line which ſeparates the whorls, and which is ſometimes ſulcated, crenulated, or ſomewhat projecting. *Fig.* 10.

Pillar or Columella, is the inner part of the left lip, or column, which runs through the ſhell, from the lower extremity to the tip of the ſpire, and from which all the ſpires take their origin; the columella being ſituated as nearly as poſſible in the axis of the ſhell, and ſerving as its baſis and ſupport throughout. It is generally either flat, grooved, folded, or truncated in that part which is viſible at the opening. *Fig.* 11.

Aperture, called in familiar language, the mouth of the ſhell, is the entrance to the chamber in which the animal reſides, and is applicable to the openings of univalve and multivalve ſhells. The aperture is either entirely open, or cloſed by the operculum attached to the body of the animal, when the animal retires into its dwelling. This aperture varies in form in different ſhells, being angular, rounded, ſemilunar, linear, or otherwiſe, and ſometimes appears double, the inner margin being ſurrounded by an exterior one. *Fig.* 12.

Lip, the expanſion of the exterior part of the aperture conſtitutes the lip in the labiated ſhells, and the wing in the alated kinds. *Fig.* 13.

Beak, or roſtrum, is that part at the baſe which extends in a ſtraight or ſlightly oblique direction from the bottom of the aperture, and is larger or ſmaller in different families. In murex hauſtellum this projection is very conſpicuous. *Fig.* 14.

Canal, or gutter, an elongation of the aperture of the ſhell deſcending in a groove or gutter-like proceſs. Some kinds of roſtrated ſhells have the canal remarkably conſpicuous, forming a ſinus from the aperture throughout the whole length of the beak. *Fig.* 15.

Umbilicus is the opening, or perforation in the lower part of the body, or firſt whorl of many ſpiral univalves, and is very conſpicuous in a number of the trochus and nerita genus in particular. This umbilical perforation runs in a ſtraight line from the baſe to the ſummit of the ſhell, forming throughout a ſpiral groove or gutter, which is wide at the entrance, and tapers gradually towards the apex. In the Linnæan nerita canrena, the ſtructure of the umbilicus is well diſplayed, but is ſtill more obvious in the ſtaircaſe ſhell, trochus perſpectivus. This opening occurs in many ſhells at the baſe of the pillar. *Fig.* 17.

The umbilicus is either ſmooth, carinated, crenulated, or beſet with tubercles, and ſometimes denticulated. It is either entirely, or only partially diſcloſed, being ſometimes half cloſed up by a gibboſity, or other projection at the aperture, in which caſe it is termed by conchologiſts ſemi-umbilicated, or ſub-umbilicated. Sometimes the pillar ſpreads ſo far over as nearly to cloſe up the entrance.

A ſhell without an umbilicus is termed imperforate; ſometimes the term imperforate implies that it has neither umbilicus, nor caniculation at the baſe.

Operculum is a teſtaceous or cartilaginous appendage peculiar in a conſiderable degree to the univalve tribe of ſhells, and thoſe only of the ſpiral or turbinated kinds. This appendage is not connected with the ſhell, but the animal, and ſerves like a lid or little door, to protect or cloſe up the aperture of the chamber when the creature retires within its habitation. Shells of this kind are diſtinguiſhed by the name of *cochleæ operculatæ*, by ſome of the elder conchologiſts. The opercula are often ſmall in compariſon to the ſize of the ſhell to which they belong; their form various in different ſpecies; and their ſubſtance in ſome of a horny texture, and, in others, teſtaceous or approaching the nature of ſtone. Their figure in common is either perfectly round, elliptical, oval, or elongated, and ſometimes wrought with ſpiral work, or concentric lines.

The operculum is commonly adherent either to the upper part of the poſterior end of the foot, or, as denominated by ſome writers, the pedeſtal of the animal, or at its extremity, ſo that when the animal moves along, the operculum appears at a diſtance from the ſhell. In the neritæ, ſome of the turbines, and certain other kinds, which have the aperture of a round, ſemicircular, or oval form, the operculum is uſually of a ſize adapted to the extreme circumference of the opening, or nearly ſo, and fits cloſe at the entrance; or is very little drawn into the opening when the animal retreats into its chamber. On the contrary, in the volutæ and ſome other ſhells which have the mouth of a lengthened or linear form, the aperture is comparatively very ſmall, and the operculum might be drawn far into the ſhell, when the animal retreats into its ſpiral receſs before the channel becomes ſufficiently contracted to be completely cloſed up by this appendage.

The teſtaceous opercula eaſily diſſolve in acids; it therefore happens that when put into vinegar they move briſkly to and fro for ſome time, by the ebullition, hence they have obtained the name of creeping ſtones among the common people. The cartilaginous opercula are not affected by this proceſs. The blatta byzantia, of medical writers, are of this latter kind; being the true opercula of two or three different kinds of ſhells, very abundant in Paleſtine, and other parts of the eaſtern world.

Some of the ſpiral, or turbinated land ſhells, are likewiſe of the operculated kinds, but differ from the foregoing, as they form a new lid, or operculum, every year, or oftener, eſpecially at the approach of winter, when the animal is prompted to make this proviſion, in order to guard itſelf from the inclemencies of the weather. It is formed by a viſcous moiſture emitted from the body of the animal, and which condenſes into a kind of tough coriaceous ſubſtance of pretty conſiderable thickneſs; this covering is never attached to the body of the animal; it merely covers the entrance, nor is it ever wrought like the true opercula of marine ſhells with ſpiral or concentric lines.

Operculated ſhells are chiefly the turbinated kinds of univalves; the opercula of the balani among the multivalve ſhells conſiſt of four pieces, and partake rather of the nature of valves, both in ſubſtance and appearance, than of the opercula above deſcribed.

Involuted ſpire, revolved ſhells (univalvia turbinata claviculæ intus reconditæ, &c. Da Coſta). Theſe ſhells turn or revolve inſide, or have the whorls concealed within the body of the ſhell as the nautilus and cypræa. An involuted ſpire is ſhewn at *fig.* 18.

Chambers are the ſpaces or diviſions formed in the interior part of ſhells by intervening partitions, a kind of articulated ſtructure elucidated completely in the nautilus.—By a chambered ſhell we ſometimes underſtand only that it has ſome laminiform, ſubſpiral, or other proceſs within, as in patella Chinenſis. *Fig.* 19.

Siphunculus, the ſmall canal which penetrates in a ſpiral direction through the chambers of the nautili. An organ of this nature is obſervable alſo in the ammonitæ. *Fig.* 20.

Epidermis is a kind of ſkin or coating, with which the exterior ſurfaces of many ſhells, both of the univalve and bivalve tribe, are covered. It is conſidered as a ſort of perioſteum or membrane, deſigned by nature to defend the ſhell from accidents and aid their growth, and to prevent other teſtaceous or marine animals from fixing their habitations on theſe ſhells, as they do upon moſt bodies in the ſea, where there is no power of reſiſtance. The epidermis is a genuine covering formed by the animal itſelf, peculiar to ſome kinds, and as conſtantly never obſerved on others. There is no doubt but the animal to which this ſort of covering is peculiar, poſſeſſes a proper apparatus for its conſtruction. The ſtructure of this epidermis, it ſhould be added, is very diſtinct in different ſhells, conſiſting in ſome of a very thin pellucid film, and in others laminated, pilous, velvetty, fibrous, or rugged. Few ſhells, having a rugoſe ſurface, are deſtitute of this external covering or epidermis.

The ſpines, protuberances, longitudinal ridges, carinations, furrows, ſtriations, punctations, granulations, and other peculiarities of what is termed the "outſide work" of the ſhells, are to be regarded only as ſpecifical diſtinctions of ſhells; and the variegations of colours, ſpots, and other ſimilar particulars, are to be conſidered in the ſame point of view. Thoſe peculiarities are not obſervable in many ſhells in their natural ſtate, being concealed beneath the thick epidermis which inveſts them; in others which have the epidermis thin and membranaceous, they are perceptible, but the beauty of the ſhell is diſcloſed only upon removing this exterior covering. See *fig.* 21.

Bivalves,

Or ſhells of two valves united by means of a cartilage, hinge, connection of the teeth, or other proceſs. In order to conſtitute a bivalve ſhell, it is only requiſite that it be furniſhed with two connected valves, without regard to their reſemblance in form or dimenſions. Some of the bivalves have both valves formed alike; in others they differ only in a ſlight degree, and again in others they are altogether diſſimilar. The firſt of theſe is well exemplified by the ſolen genus; in that of the Linnæan tellinæ, we find examples both of the equivalve ſhells, and thoſe with the valves ſlightly different: of the laſt-mentioned kinds we have many, as the oſtrea, ſpondylus, and anomia. Bivalve ſhells are often much compreſſed, ſome are gibbous, and when viewed at the ſide, or facing the ligament, have a cordated appearance, as in venus, and the Linnæan chama cor. Shells, having both valves alike, as before obſerved, are called equivalve. Equilateral valves imply thoſe which have both ſides of the ſame valve alike, as for inſtance, when a longitudinal line is drawn from the beak to the oppoſite margin, the ſpace on each ſide the line is diſtinguiſhed by the appellation of the right and left ſide; and when the form of both thoſe ſpaces correſpond, the ſhell is equilateral, as in the ſcallops (oſtrea, Linn.): the inequilateral valves are the reverſe of this, a line drawn as above deſcribed, from the beak to the oppoſite margin, preſenting two ſides of a very different ſhape, as we ſee in moſt of the mactra, the donax, and tellina genera, and in the mya truncata eſpecially. Subequilateral ſhells, or thoſe having the valves nearly equal at both ſides, are ſufficiently elucidated by ſhells of the cardium, or cockle genus, which are ſtrictly "bivalvis ſubæquilatera."

All bivalve ſhells do not completely cloſe their ſhells, though moſt of thoſe before mentioned do ſo, ſuch as the ſcallop, the donax, tellina, and cardium: in ſeveral other tribes of bivalves, when the ſhells are ſhut as cloſely as their form will allow, they ſtill exhibit a kind of hiatus or gaping, either at the anterior or poſterior end, or at both; and in ſome, when the valves are ſhut, both the anterior and poſterior parts are cloſed, but an opening appears on one ſide of the beak; this laſt-mentioned character is very obvious in chama gigas.

One of the firſt circumſtances to be conſidered, is which part of a bivalve ſhell ought to be deemed the baſe, becauſe when this is determined, every other part will fall progreſſively in their relative order under our obſervation. We name that part of the margin or limb which is ſituated in a direct line oppoſite the beak, the baſe of the ſhell. Linnæus, in order to eſtabliſh the characters, and afford ſome apparent reaſon at leaſt for the application of the terms he beſtows on the different parts of bivalves, reverſes this poſition of the ſhell, and deſcribes the beaks as the baſe of the ſhell. But the fact is, the natural poſition of the ſhell is in immediate contradiction to his axiom, for the beaks are always uppermoſt, being either immediately vertical, or with a ſlight inclination obliquely, when the animal moves along with its teſtaceous covering on the back. A ſolitary example will perhaps occur occaſionally, in which the beaks may be conſiderably inclined when the animal crawls, but none, we believe, are known which open the valves upwards, and proceed with the beaks under the body. The beaks, if only for this reaſon, are to be conſidered as the ſummit, and the margin oppoſite as the baſe. Many of the bivalves are deſtitute of the locomotive power, or at leaſt do not poſſeſs it in any material degree.

Baſe of bivalve ſhells, exemplified in venus verrucoſa. *Fig.* 22.

Summit, a word applied in a general manner to the top or moſt elevated part of the two protuberances obſervable in the greater number of bivalves. Da Coſta calls that part of the ſhell, in which the teeth or hinge is placed, the ſummit or apex; we regard it as the moſt elevated part of the beaks. *Fig.* 23.

Beak, the pointed termination, apex, or tip of the protuberances laſt-mentioned, and which, in many ſhells, turn ſpirally downwards, or obliquely, ſo that the beak itſelf is ſeldom the moſt elevated part of the ſhell; though it is ſo ſometimes, as for inſtance in the mytilus edulis, or common muſcle. *Fig.* 24.

Sides, the lateral parts of the valves diſtinguiſhed by the epithet of right and left ſide; in common language, the two valves of a ſhell are called the ſides, but it is not underſtood as a term in conchology in this view. *Fig.* 25.

Margin, or *limb*, the whole circumference or outline of the ſhell, when laid flat down on one valve. *Fig.* 26.

Diſk, the convex centre of each valve, or exterior ſurface *Fig.* 27.

Anterior ſlope, that part of the ſhell in which the ligament is ſituated; in the front view of the anterior ſlope, the beaks fall back, or behind. *Fig.* 28.

Poſterior ſlope, that immediately oppoſed to the former, and in which the beaks of the ſhell turn forward. *Fig.* 29.

Lunule, the lunulated depreſſion below the beaks, either on the anterior or poſterior ſlope, and ſometimes on both; they may be diſtinguiſhed under the appellation of anterior or poſterior lunules, according to the ſlope in which they are ſituated. *Fig.* 30, ***a***, ***b***.

Cartilage of the hinge, called alſo the ligament of the hinge, the ſubſtance of a flexible, fibrous, and ſomewhat horny nature, by means of which, the two valves are united near the beak. *Fig.* 31.

Ears, the lateral proceſſes near the beaks, as in the ſcallop tribe: thoſe occur either on one ſide, or on both. *Fig.* 32.

Ligament perforation, the opening, or aperture, through which the ligature of the animal paſſes in the anomia genus, by the aſſiſtance of which it faſtens itſelf to the rocks, or other bodies; in ſome it is ſituated in the flat valve, in others at the beak of the gibbous valve. *Fig.* 33.

Length and breadth of the ſhell. The length is meaſured from the cartilage or beak to the margin below, the breadth is of courſe taken in the oppoſite direction. The breadth of many bivalve ſhells exceeds their length: ſome remarkable inſtances of which occur in the ſolen tribe. *Fig.* 34.

Inſide of the valves exhibits the concave ſurface (*concavitas concharum*), *fig.* 35.

Hinge, the point of union between the two valves, formed by the connection or articulation of the teeth in both valves, or by the teeth in one valve, fitting into hollows or ſockets in the valve oppoſite. The amazing variety of ſtructure obſervable in the hinge of different tribes of ſhells renders this one of the moſt eſſential characters in the generical definitions of ſhells. The teeth in ſome are ſmall and numerous, in others thick, ſolid, and few in number, or ſometimes ſingle, long, ſpatuliform, laminiform, acicular, &c. the principal of which may be divided into *inarticulate* hinge, when only furniſhed with calloſities, or having no viſible teeth; *articulate*, when it has teeth, but only a ſmall number; and *multarticulate*, when the teeth are numerous. Theſe variations will be further explained under the reſpective genera.

Cicatrix, the impreſſion on the inſide of the valves indicating the point of connexion between the muſcles of the animal, and its ſhell. In ſome kinds, as the common oyſter for example, there is only one ſuch muſcular impreſſion in each valve, in others there are two, and ſome have more. The cicatrix is not of the ſame figure in all ſhells, being either round, ſemi-ovate, lunate, or elongated, in different kinds. *Fig.* 37.

Byſſus, the appendage called the beard; by means of which ſome bivalves faſten themſelves to the rocks. *Fig.* 38.

The imbrications, furrows, ſpines, tubercles, reticulations, ſtriations, or other peculiaritis of the ſame nature, as well as the variations of colours, obſervable on the exterior ſurface of bivalves as before ſtated in ſpeaking of univalves (and which is indeed equally applicable to the multivalves, and conſequently to ſhells of every deſcription), though they afford us the beſt ſpecifical diſtinctions poſſible, do not claim our regard as primary characters, and are therefore paſſed unnoticed in this place.

Multivalves.

The ſhells of this order are few, compared with either of the preceding; and the terms propoſed for thoſe, are applicable for the moſt part to the multivalves. The following require more explicit mention.

Baſe, that part of the ſhell upon which it reſts: in the lepas tribe it implies the part immediately ſeated upon the ſtem or pedicle; in the balani, the baſe is generally larger than the ſummit, and is the bottom by means of which the ſhell is fixed upon the rocks, or other extraneous bodies. *Fig.* 39.

Ligament, the ſubſtance, whether membranaceous or tendinous, which ſerves to connect the valves together. The connexion of the valves in ſome multivalves is formed by the parts of one valve locking into another. *Fig.* 40.

Operculum. The balani have the aperture at the ſummit cloſed by means of four ſmall pieces or valves, which are commonly called the operculum; theſe opercula of the balani are, however, very different from thoſe of univalve ſhells. *Fig.* 41.

The various parts of which teſtaceous bodies conſiſt being ſufficiently conſidered and explained, our attention is next directed to the different modes of arrangement into which thoſe bodies have been diſtributed by the principal writers on conchology, and a general inquiry into a variety of other particulars connected with the hiſtory of the ſcience. In this inveſtigation we ſhall avail ourſelves in ſome meaſure of the method pointed out by the learned author of the "Claſſes Conchyliorum" (Bergen), the valuable "Bibliotheca Hiſt. Natur. Bankſiana" of Mr. Dryander; "La Conchologie" of Favanne; the "Hiſtorical Account of Teſtaceological writers," by Dr. Maton and Mr. Rackett, inſerted in the "Tranſactions of the Linnæan Society," and the labours of many others, in addition to our own, as will appear in the courſe of the following obſervations.

The name of Ariſtotle ſtands high in the records of philoſophy. He is emphatically called by Dr. Pultney, in ſpeaking of teſtaceological writers, the father of natural ſcience; and by Dr. Maton the inventor of ſyſtem. Our reſpect for the Macedonian philoſopher is great, nor would we willingly appear to detract from his diſtinguiſhed merit; yet we muſt confeſs we never could conceive it poſſible, with all the ability this early writer poſſeſſed, that, riſing as it were from primæval darkneſs, he could at once ſurvey the multifarious objects of creation, and produce a ſyſtem of natural objects ſo complete as that which we are diſpoſed to acknowledge excluſively as his own. He muſt have derived conſiderable aid from ſources then extant, and which are now for ever loſt to the world. The hiſtory of mankind throughout all ages will teſtify beyond a doubt that the acquirement of human knowledge is ſlow and progreſſive; and the knowledge of Ariſtotle in natural ſcience was in particular of that kind which in a great meaſure could be attained only from the obſervations of many. Under the patronage of Philip, the Macedonian monarch, and of his ſon Alexander, the hero of the world, no advantages which Ariſtotle could derive from the ſtudy of books would be denied him, and can it be imagined from ſo many hundred thouſand volumes as were extant in his time, and at his immediate command, Ariſtotle was unable to obtain information; or that among this immenſe number there were none on the ſubject of Ariſtotle's inquiries? This writer would certainly avail himſelf of the recorded labours and diſcoveries of former ages, and eſpecially would not neglect to cultivate an acquaintance with the ſciences of the Egyptians, upon all which his own ideas might improve. Indeed, if we miſtake not, however viſionary it may appear, the latter was the genuine ſource from whence his knowledge of natural philoſophy was derived. Egypt, not Attica, was the cradle of ſcience.

To the writings of Ariſtotle the learned world is certainly indebted for the firſt account we probably ever may poſſeſs of the ſtate of natural ſcience at the early period in which he lived; it is a fortunate circumſtance for the cauſe of learning that his labours have ſurvived the havoc of deſtructive time. This ſyſtem is a production that would confer credit on any naturaliſt of the fourteenth century, much leſs of a period almoſt two thouſand years before. The claſſification, or diviſion of ſhells contained in the fourth book of "Ariſtotle's Hiſtory of Animals," has ſtood the teſt of ages, and, with improvements, rendered neceſſary by recent diſcoveries, is in general adopted by very late writers. Linnæus was in a great meaſure himſelf indebted to his ſyſtem for the outlines of his own, for many of his genera, and for the names under which thoſe genera are retained, even in the moſt improved ſtate of his "Syſtem of Teſtaceology."

The "Oſtracodermata" of Ariſtotle, for ſuch is the title of his conchological productions, preſent us with a valuable ſcheme of ſhells. He divides all ſhells into two principal claſſes, Μονόθυρα and Δίθυρα, or univalves and bivalves.

The univalves he ſeparates into two parts; namely, thoſe of the turbinated kind, as Κοχλιαι, or *limaces*, Κωκάλια, *cocalia*, the *purpuræ*, Πορφύραι, *buccina*, Κήρικες, &c.; and ſuch as are leſs turbinated, as Λεπὰς, the ſea-ears, or haliotis, and Νηρῖται, *neritæ*. Among the latter, he includes ſeveral families of the echinus, or ſea-eggs, Εχινος, a tribe of cruſtaceous animals retained by almoſt every writer among the ſhells, till they were ſeparated by Linnæus. He alſo ſpeaks of the animals inhabiting the cocalia, purpureæ, and buccina.

The bivalves he diſtributes into ſeveral families; he has Κτένες, or *pectines*, Σωληνε, *ſolenes*, and Πίννα, *pinnæ* or ſea-hams, all of which genera have been retained by Linnæus, and later authors.

Ariſtotle commits one remarkable error, however, in placing the opercula of ſome turbinated univalves as a genuine tribe of ſhells. This error, which indeed we think excuſable conſidering the age in which that philoſopher lived, is mentioned by ſeveral authors as an objection to his accuracy of diſcrimination, and is commented on by Bergen in the following obſervation.

"Ex umbilicis τοῖς κόχλοις videtur Ariſtoteles peculiare conchyliorum genus perperam conſtituiſſe, ſunt enim proprie opercula quorumdam turbinatorum, quæ certo anni tempore foribus cochlearum quaſi inſtar clauſtri agglutina inveniuntur quæque poſtea decidunt & nullius amplius uſus pro ipſo animalculo." Ariſtotle flouriſhed 322 years before Chriſt.

C. S. Pliny wrote largely upon conchology; the ninth book of his "Hiſtory of Animals" is very copious: it is more diffuſe than that of Ariſtotle, and the arrangement is unmethodical, but this is ſtill an uſeful work, and may be conſulted with advantage. Many of the terms employed by modern conchologiſts are to be found in his work. Pliny conſtitutes thirty-three families, which are diſtinguiſhed chiefly by the form and ſuperficies of the ſhell, as *plana, concava, longa*, and *lunata, lævis*, and *rugata*; by the ſhape of the margin, as *margine in mucronem emiſſo*; *margine fortis effuſo*; and *margine intus replicato*. The ſinuoſities, or projections of the ſhell, the connexion of the valves, and other ſimilar characters, were alſo taken as diſtinctions of the different families.

In Pliny's time the Romans are ſuppoſed to have poſſeſſed conſiderable opportunities of acquiring a knowledge of ſhells, as their navigation was extenſive, at leaſt in the Mediterranean and the Red Sea.

The conchological writings of Ælian are held in leſs repute than either of the preceding; he dedicates ſome conciſe chapters to this ſubject in his work entitled, "Περι Ζωων [illegible]."

After the dark ages which ſucceeded, Vincentius Bellovacenſis was one of the earlieſt writers on this ſubject. His "Speculum naturale," publiſhed in folio, in the year 1494, contains a deſcription of the murex, purpura, oſtrea, and a few other remarkable ſhells, extracted chiefly from the works of Ariſtotle and Pliny, and intermingled with the abſurd and ſuperſtitious notions of the times. The works of Albertus Magnus, entitled "De Animalibus," which appeared in folio in 1495, contains deſcriptions of ſome ſhells; and ſo likewiſe does that of Adam Lonicerus, "Hiſtoriæ naturalis opus novum," publiſhed in 1551.

The firſt writers who diſtinguiſhed themſelves by any attention to the ſtudy of conchology, after the revival of letters in Europe, were Belon, Rondeletius, and Geſner. Belon is celebrated for his travels in the Eaſt, and he was perhaps one of the firſt learned men who travelled principally with a view to natural ſcience; on his return to Paris, in 1553, he publiſhed, beſides other works, an octavo volume, entitled "De Aquatilibus." The part appropriated to conchology is not extenſive, it is rather elementary and philological than deſcriptive; but contains figures of a few ſhells engraven on wood. The work of Rondeletius (profeſſor of phyſic at Montpelier) appeared two years after, A. D. 1555; this bears the title of "Univerſa Aquatilium Hiſtoria," and contains upwards of one hundred ſpecies of teſtaceous animals. His reſidence on the coaſt of the Mediterranean afforded him abundant opportunity of inveſtigating the ſhells of that ſea, and their animal inhabitants, a ſubject of inquiry to which he paid ſome attention. This author received much aſſiſtance from the labours of Ariſtotle and Pliny. The "Commentaries" of Matthiolus, embelliſhed with a few cuts of ſhells, contain nothing of material intereſt, except what has been collected from former writers; ſeveral editions of this work appeared between the years 1566 and 1683, in Spain, Italy, France, and the Venetian ſtates. In 1558, the work of Conrad Geſner, "De Piſcium et Aquatilium Animantium Hiſtoria," made its appearance, and acquired much reputation. Dr. Pultney pays a high compliment to Geſner for his unparalleled induſtry, and ardent love of natural hiſtory, and obſerves, that he not only collected all the philological, hiſtoric, and deſcriptive erudition of the ancients on this ſubject; but beſides his own copious comment on their writings availed himſelf of what Belon and Rondeletius, his contemporaries, had done, to which he added much original matter of his own, having deſcribed and figured many of the Mediterranean ſhells and ſeveral of thoſe diſcovered in the Indian and Arabian ſeas. This comment is correct, but of the ſyſtem propoſed by Geſner for the claſſification of ſhells, we muſt ſpeak more fully. This author divides all ſhells into four claſſes, *univalvia, bivalvia, turbinata*, and *anomala*. The firſt contains only two genera, lepas and auris marina; or the limpets, and ſea ears (lepas derived from the Greeks, and ſynonymous with patella, being the name applied by old conchologiſts to the limpets, ſince called patella by Linnæus). His bivalvia claſs contains many genera, as oſtrea, ſpondyli, mytili, tellinæ, chamæ, pinnæ, ſolenes, and eight others. In the third claſs turbinata he has ten genera, as ſtrombi, murices, buccinum, turbo, trochus, nerites, &c. all which names will be recognized by the Linnæan ſtudent as thoſe employed by Linnæus. His fourth claſs anomala, is exceptionable, as it contains, beſides the balani, pencilla marina, tubuli marini, and echini, the ſtellæ marinæ, or ſtar-fiſh, and caput meduſæ, neither of which have ever been conſidered by other naturaliſts as appertaining to conchology. Bergen admits this as a material objection to his ſyſtem, "Peculiarem claſſem anomalorum condidit, ad quam, ut mihi videtur, adnumerandae. Idem valet de capite meduſæ." His ſeparation of the balani from the two firſt claſſes is countenanced by all late writers.

Geoffrey Linocier, in his "Hiſtoire des Poiſſons," publiſhed at Paris in the year 1558, gives an account only of a ſmall number of ſhells; the work not being devoted to the ſubject of conchology: neither is that of Imperato, publiſhed at Naples in 1599; though it contains an account of ſome ſpecies, this production relating chiefly to foſſils; it bears the title of "Dell'Hiſtoria di Ferrante Imperato Napolitana."

The work "De Mollibus Cruſtaceis, Teſtaceis, et Zöphytis," of Aldrovandus, appeared in folio, in 1606, and is well known. His arrangement conſiſts of three claſſes, *turbinata, bivalvia*, and *univalvia*. Among the turbinata he includes the nautilus, and alſo the buccinum, and other ſpiral ſhells, together with the echini. The bivalve claſs is the ſame with that of all other writers, as oſtrea, tellina, and pinna, but beſides theſe includes the multivalve ſhells of late authors, ſuch as the balani and pholades. The third claſs, or univalvia, contains the lepades, patellæ, auris marina, concha venerea, concha perſica, and pencillus marinus. The figures conſiſt of cuts on wood, and are rudely executed.

Fabius Columna, in 1616, publiſhed a treatiſe on ſhells, or rather a monographia on the purpura, entitled "De Purpura ab animali teſtaceo fuſa, de hoc ipſo animali, aliiſque rarioribus teſtaceis quibuſdam." A new edition of this work, with annotations, appeared in 1675, by John Daniel Major.

In the year 1616, a work entitled "Faſciculus rariorum et aſpectu dignorum varii generis, quæ collegit et ſuis impenſis æri ad vivum incidi curavit," from the pen of Baſil Beſler, apothecary at Nuremberg, made its appearance; it is in Latin and German, and two of the plates are appropriated to the ſubject of ſhells.

Chiocco, the deſcriber of the "Muſæum Calceolarium," publiſhed at Verona, in 1622, gives a full account of the ſhells contained in that collection, with ſpecific characters in the Latin language, borrowed for the moſt part from other authors. This muſeum was begun by Benedict Ceruto, a phyſician, and afterwards enlarged by Calceolari. The figures of the ſhells occupy ſix plates. It appears to be the firſt work that was written profeſſedly as a deſcription of a muſeum of natural curioſities, the account of the ſame muſeum by J. P. Olivius, publiſhed in 1584, alone excepted.

A phyſician of Hamburgh, Schonvelde, was author of an account of aquatic animals, both of the marine and freſh water kinds, found in the duchies of Sleſwick and Holſtein, which contains ſeparate chapters on oyſters and muſcles. The obſervations relate chiefly to the culinary uſes of the animals. This book bears date 1628.

The work of Niercembergius, "Hiſtoria Naturæ," contains an account of a number of ſhells, but does not preſent us with any figures. It was publiſhed at Antwerp, in 1635.

In the firſt edition of the "Gazophylacium Rerum Naturalium" of M. P. Beſler, the brother of Baſil Beſler before-mentioned, are twenty-four plates, containing, among a variety of other ſubjects, natural and artificial, a few figures of ſhells, with a conciſe deſcription in Latin of each, under the reſpective figures. The ſecond edition compriſes ſix additional plates and a preface in German. The firſt was publiſhed in 1642, the latter not till the year 1733.

The ſynoptical catalogue of Seger, "Synopſis Methodica rariorum tum Naturalium tum Artificialium quæ in Muſæo D. Olai Wormiis aſſervantur," was printed at Copenhagen in 1653; and, as the title informs us, deſcribes both the natural and artificial curioſities in the muſeum of Wormius. This was ſucceeded in 1655 by a more ample account of the muſeum by Olaus Wormius, from which it appears to have contained many of the teſtaceous tribe, one only of which is however figured; this is the Linnæan lepas anatifera, to which is attached the whole of the abſurd tale related by credulous writers of that day reſpecting the bernacle gooſe, which was ſuppoſed to be engendered, and hatched in thoſe ſhells! The ſixth, ſeventh, and eighth chapters of this work are deſcriptive of ſhells; theſe he divides into univalvia, bivalvia, and turbinata.

In 1672, the "Muſeum Moſcardianum," or "An account of the collection of natural curioſities belonging to an Italian nobleman, Conte Lodovico Moſcardo," appeared at Padua. The ſhells are compriſed in twelve plates, and the ſubjects are noticed ſpecifically. Another edition of this work made its appearance in 1672, at Verona, the city where that noble collector reſided, which, beſides the twelve plates above-mentioned (and which are engraven on copper) contains ſome cuts on wood.

The work "Hiſtoria Naturalis de Exanguibus Aquaticis" of Jonſton, is an extenſive production, a compilation for the moſt part from others, and is embelliſhed with a number of engravings, comprehending altogether twenty copper plates of molluſca and teſtacea. Like Aldrovandus, he diſtributes all ſhells into three principal claſſes, turbinata, bivalvia, and univalvia. His turbinata are ſubdivided into two ſections, "* in anfractum torta;" and "* * in orbem circumacta." In the firſt of theſe, we find the nautilus, purpura, buccinum, murex, conchylium, and blatta byzantina; and in the other, turbines, trochi, nerites, cochlea, and echini. Except the multivalves balani, and pholades, which he includes in his claſs bivalvia, the bivalves are thoſe of later authors; the claſs univalvia contains two genera, the lepas or patella, and concha venerea. This work was publiſhed at Amſterdam in 1657. Eight years after which (1665) the ſame author deſcribed a few of the more remarkable ſhells in his "Thaumatographia Naturalis."

About this time De Rochfort publiſhed an account of the ſhells of the Caribbee iſles, illuſtrated with a plate of five ſpecies, which he conſidered moſt remarkable for ſhape and beauty. This work bears the title of "Hiſtoire Naturelle et Morale des Iſles Antilles." Jean Baptiſte du Tertre, alſo, publiſhed on the ſame ſubject, "Hiſtoire generale des Antilles habitées par les François." Paris 1667.

The "Muſæum Gottorpianum," or "Muſeum of the Duke of Holſtein-Gottorp," was deſcribed by Adam Olearius, in 1666. This is in quarto, and of thirty-ſix plates which it contains, five conſiſt of ſhells, all which are referred to by Linnæus in various parts of his Syſtema. Another edition came out in 1674.

In the "Pinax Rerum Naturalium Britannicarum," publiſhed in London in the year 1667, by Merret, we are preſented with the earlieſt catalogue of the natural productions of Great Britain, extant. This is in octavo. The conchological part, which he calls "Teſtacei," occupies about half a page, and contains references to the voluminous works of Rondeletius, Geſner, Aldrovandus, and Jonſton.

Charleton, a phyſician of conſiderable celebrity, publiſhed, in London, in the year 1668, his "Onomaſticon Zoicum," in which a new arrangement appears. This author divides all ſhells after the manner of Aldrovandus and Jonſton, into turbinata, univalvia, and bivalvia, from whence it will be perceived, he inverts the order of the two laſt claſſes. His turbinated genera are literally tranſcribed from Jonſton. The univalves contain ten genera, five correſponding with thoſe of Aldrovandus, lepades, auris marina, concha venerea, concha perſica, and pencillus marinus, to which are added tubuli teſtacei, balani, conchæ anatiferæ, dentalia and entalia. His bivalve genera are leſs happily defined: in addition to thoſe eſtabliſhed by Jonſton, he forms others in imitation of Pliny, taken ſolely from the ſcaly aſperities, ſpines, or ſmooth exterior ſurface of the ſhells, after previouſly dividing the whole claſs of bivalves into two orders "conchæ aſperæ, and conchæ læves."

Nothing appeared from this time of material conſequence on the ſubject, till the re-publication of the treatiſe of Fabius Columna, by Dr. Major. In the interval, Steno publiſhed a work, entitled, "De ſolido intra ſolidum naturaliter contento Diſſertationis Prodromus," which contains ſome pages devoted to an explanation of the fabric and texture of teſtaceous bodies. Boyle deſcribed ſome experiments on the phenomena of ſhell-fiſh, particularly of the oyſter, under an exhauſted receiver, in the Philoſophical Tranſactions of the year 1670; and Willis, in 1672, the anatomy of the oyſter, in his "Exercitationes de Anima Brutorum;" but theſe are only phyſiological diſſertations. The work of Dr. Major includes a new ſyſtem annexed to the hiſtory of the purpura previouſly publiſhed by Fabius Columna, and likewiſe a "Dictionarium Oſtracologicum;" and is beſides illuſtrated with a number of wood-cuts. All ſhells are divided by this ſyſtematiſt into two claſſes, univalvia and plurivalvia, the firſt of which are ſubdivided into ſeveral ordines, the characters of which are taken from the form and ſtructure of the opening of the ſhell, its turbinations, ventricoſity, protuberances, or general figure. The genera conſtituted of thoſe ſhells are few, as penicilli marini, pyramidaliter dentata, lepades vel patellæ, auris marina, conchæ natatiles, concha venerea, nautilus, murices, turbo, turbines terreſtres, and buccina. His claſs plurivalvia is ſeparated into two orders, bivalvia and plurivalvia, the firſt of which conſiſts of his conchæ ſtriatæ, conchæ verrucoſæ, conchæ rugoſæ, pectines, oſtreæ, and conchæ anomiæ; the plurivalvia only two genera, conchæ anatiferæ and balani, or glandes. The two latter genera are thoſe united by Linnæus, under the name of lepas, and which, before the time of Major, had been improperly arranged, either among the bivalves, or univalves, except by Geſner, who, aware of this impropriety, places the balani at the head of his claſs anomala. This production of Major's appeared in 1675.

Legati was author of the "Muſeo Coſpiano," printed at Bologna in 1677. The baſis of this collection was laid by the celebrated Aldrovandus, whoſe hand-writing ſtill remains affixed to many ſpecimens that formed the ſubjects of Legati's deſcription. Ferdinando Coſpi, a Bologneſe patrician, afterwards augmented it ſo conſiderably, that his name became attached to it; and the univerſity of Bologna, to which it was at length preſented, conſidered it one of their moſt valuable acquiſitions. There are not many figures of ſhells in the "Muſeo Coſpiano," but the deſcriptions of this tribe are numerous, and very ample.

In the twelfth volume of the Philoſophical Tranſactions, is a "Relation concerning Barnacles," by ſir Robert Moray. This credulous obſerver gives a deſcription illuſtrated by a rough outline of lepas anatifera, from which he aſſerts, that young geeſe may actually be ſeen to emerge.

Harderus, in a diſſertation entitled, " Examen anatomica Cochleæ terreſtris domiportæ," affords an anatomical deſcription of helix lucorum. This appeared at Baſil in 1679. Two years after Grew publiſhed his " Muſæum Regalis Societatis," or " Catalogue and deſcription of the natural and artificial rarities belonging to the Royal Society, and preſerved in Greſham college, London." This was the earlieſt work of its kind that appeared in the Engliſh language. The ſhells are deſcribed in two chapters, the firſt comprehending univalves, the ſecond bivalves and multivalves, illuſtrated with about forty figures, to which the current Engliſh names are annexed.

Buonanni was contemporary with Grew, and in the ſame year (1681) publiſhed at Rome his " Ricreazione dell' Occhio, e della Mente nell' oſſervation' delle Chiocciole," a work of very ſuperior merit, and eſteemed the firſt profeſſedly written, at any conſiderable length, upon the ſubject of conchology. This was originally printed in Italian; but was three years afterwards re-publiſhed, with additions, in Latin, under the title of " Recreatio Mentis et Oculi in Obſervatione Animalium teſtaceorum." The firſt work contains a ſeries of 450 figures, the number of which is augmented to 550 in the Latin re-publication. Theſe are valuable for reference, as being conſtantly mentioned in the Linnæan Syſtema Naturæ; their greateſt fault (and it is certainly a material objection), is that many of the ſhells are reverſed by the inaccuracy of the engraver, ſo that the apertures of the ſpiral or turbinated ſhells turn to the left inſtead of the right. The ſubjects were obtained chiefly from the celebrated muſeum of Kircher; a deſcription of which was afterwards given by Buonanni under the title of " Muſæum Kircherianum."

The deſcriptions are not entirely approved by late writers; they are conſidered too looſe and deſultory, or too conciſe and uninſtructive. His diſtribution of ſhells comprehends *univalvia non turbinata, bivalvia*, and *turbinata*. In the inferior diviſions, this author, Dr. Maton obſerves, " has ſtrangely ſeparated ſpecies naturally allied to each other, as, for inſtance, the ſerpulæ, dentalia, &c. are left out of the firſt claſs, and, as well as the porcellaneæ, diſtributed under the third; and, with equal want of conſiſtency, the haliotis and nautilus (genera manifeſtly turbinated) are placed among thoſe which he terms " univalvia non turbinata." The ſame objection is urged by Bergen againſt the ſyſtem of Buonanni. " Hic A. tres condidit conchyliorum claſſes; univalvium, non turbinatorum, bivalvium et non turbinatorum, ſed partim aliena immiſcuit, partim neceſſaria omiſit. Sic in prima claſſe merito deſiderantur pencilli marini et porcellaneæ, quas perperam ad turbinatas refert. Sic malo conſilio aurem marinum, et nautilium huic primæ ſociavit claſſi, cum manifeſte ex turbinatorum gente ſint." Buonanni is blamed alſo for admitting the pholades and conchæ anatiferæ into his ſecond, or bivalve claſs; but it ſhould be remembered, in this reſpect he only imitated the example of moſt ſyſtematic writers; Geſner places the pholades among the bivalves; Aldrovandus gives both the pholades and concha anatifera in that claſs; and Jonſton the former. Linnæus, we are to recollect, like the latter, conſiders the pholades as bivalves in all the early editions of the Syſtema; even ſo lately as the tenth edition, they ſtand under the " bivalviæ conchæ." We may ſtill further advert to Charleton, who yet more abſurdly arranges the concha anatifera with the univalves, at the ſame time that he refers the pholades to the bivalve tribe. Major was the only writer before the time of Buonanni who diſpoſed of the conchæ anatiferæ in their natural order, which he certainly did, by arranging it in his claſs plurivalvia. In the work of Buonanni will be found many philoſophical obſervations upon the origin, nature, formation, properties, and other curious particulars relative to teſtaceous bodies.

The " Scotia Illuſtrata" of ſir Robert Sibbald, publiſhed at Edinburgh in 1684, offers an outline of another ſyſtem. The author divides ſhells into two parts, the land and aquatic kinds, or " cochleæ terreſtres," and " cochleæ aquatiles." The aquatiles are divided into two ſections, the firſt containing the freſh-water ſhells, the other thoſe peculiar to the marine element. The ſhells of both kinds are diſtributed into three families, turbinatæ, bivalves, and univalves. The ſubdiviſions of thoſe families are rudely defined, but upon the whole there is method in the claſſification; the genera are ſelected from the writings of former naturaliſts, but too ſparingly. Sibbald places the echini among the turbinated ſhells; yet this is even more excuſable than his introduction of both the pholades and balani among the univalves.

Marſigli's ſmall work on the ova of teſtaceous animals, appeared at Bologna, in 1683, under the title of " Relazione del Ritrovamenta dell' uova di Chiocciole;" a new edition of which was publiſhed at Rome in 1695. Some additional obſervations on the ſame ſubject, by Fulberti, " Refleſſioni ſopra il medeſimo Soggetto," uſually accompany this work.

Among the " Obſervazioni Naturali" of Paolo Boccone, publiſhed at Bologna in 1684, are ſome remarks not altogether unintereſting on the ſubject of conchology. He was the firſt writer who deſcribed the pediculus ceti (lepas diadema of late authors) with accuracy.

In the ſame year Detteide gave an anatomical deſcription of the common muſcle in the Leipſic Commentaries, and which was afterwards re-publiſhed in Valentini's " Amphitheatrum Zootomicum."

An elaborate paper on the purple-fiſh (buccinum lapillus) by Mr. William Cole, pointing out the mode of obtaining, and the nature of this celebrated dye, or Tyrian purple, was inſerted ſhortly after in the Tranſactions of the Royal Society. This tract was re-printed in quarto in 1689.

A production of very uncommon merit about this period made its appearance before the public, the great conchological work of Dr. Liſter, entitled " Hiſtoria ſive Synopſis methodica Conchyliorum," the publication of which commenced in 1685. The author had previouſly diſtinguiſhed himſelf by ſome excellent diſſertations on the ſame ſubject; but our attention is principally directed to this, as his moſt extenſive, if not moſt valuable, undertaking. It was publiſhed in folio progreſſively from the year 1685 to 1692.

Liſter divides his work into four books. 1. " De turbinibus terreſtribus." 2. " De Turbi. aquæ dulcis et Bivalvibus aquæ dulcis." 3. " De Bivalv. marinis, et conchis anatiferis." 4. " De Patellis Dentalibus, &c. et de Buccinis marinis."

There is no text to this work, the whole conſiſting of engravings, with a conciſe deſcription of the ſhells, and reference to their native country, where that could be aſcertained, in the Latin tongue; and ſometimes their current names in Engliſh. The plates, which are of various dimenſions, are executed with great force and ſtrength of colour by the hands of the author's two daughters, Suſannah and Ann Liſter. It is an extraordinary circumſtance, that no two copies of this work are found alike, which renders it very complex, and ill ſuited for general reference. The plates in the moſt perfect copies vary in number from 1050, to 1057, or 1067, the different copies having been augmented or diminiſhed, and the plates tranſpoſed or corrected at various times, according to the fancy of the author, or his ſubſequent diſcoveries. The moſt perfect of all the copies extant was that preſented by Dr. Liſter himſelf to the royal library at Paris. This is aſcertained by the obſervations of Davila and M. de Bure, who have taken conſiderable pains in the collation of different copies of this work. Da Coſta names that in the library of the College of Phyſicians as the moſt complete copy in London. This laſt-mentioned writer appears alſo to have collated many of the early copies of Liſter; he treats on this topic at ſome length; and, conſidering the importance of Liſter's work to the conchological ſtudent, it may not be improper to repeat the reſult of his obſervations.

"I do not think it unentertaining (ſays this writer) to relate ſome circumſtances relative to this uſeful and coſtly work, which have occurred to me, on the collation of many copies of the old editions of Liſter, and on a collation of numbers of his proof prints diſperſed among the curious by Dr. Liſter himſelf before the names and numbers on the plates were added to complete the work; theſe proof prints, which are what the print collectors ſtyle variations, will lead us to ſome curious particulars that would otherwiſe be unknown. Dr. Liſter in 1678 publiſhed his "Hiſt. Anim. Angl." in which he treats of Engliſh ſhells, and gives excellent figures of them, and good deſcriptions; he therefore deſigned this work, (his "Hiſt. Conchyl.") only for exotic or foreign ſhells, as evidently appears from the proof head plates of the firſt book. N. 8, 25, 33, 40, 43, 63, 74, 83, 99, 108, 125, and 136, which are entitled cochleæ, buccina, &c. exotica; but the word exotica was eraſed when he changed his mind to have a general hiſtory of ſhells, which probably was at the ſecond book, and the eraſement of the word exotica is even now plainly ſeen in all the quoted plates. Dr. Liſter, to complete his intended work, carried home all the ſhells ſingly to his daughters to engrave on ſingle or detached copper plates, (as is ſeen by the work) reſerving their arrangement till he had a ſufficient number, ſome not being done to his approbation, or getting better ſpecimens afterwards, he had them re-engraved, and therefore many ſhells appear twice in his work, and in ſome only the firſt engraving, while in others only the ſecond engraving is found; this circumſtance is alſo evident from the proof plates, or variations." Da Coſta further ſtates it to be a miſtaken ſuppoſition that there was only one edition of this work; there were, he ſays, certainly two, and he concludes with theſe obſervations in ſupport of his aſſertion. "However, there are marks by which theſe editions may be diſtinguiſhed by an accurate critic, *viz.* 1. The ſecond edition has ſeventy-five ſhells more than the firſt. 2. In the preface, plate IV. the third paragraph begins "Septuaginta autem, &c." 3. In plate VII., which ſpecifies the places where they are found, the firſt edition has only one column of names, whereas the ſecond edition has a name, *viz.* Fret Magel, in a ſecond column. 4. The title and all the head plates, as 1, 2, 3, 100, 106, 139, 140, &c. are printed partly in black and partly in red letters; whereas in the ſecond edition only the title, plate I., is printed in red and black letters, all the others being printed only in black letters."

The plates of this work were bequeathed to the univerſity of Oxford, and were re-publiſhed in 1770, under the direction of the Rev. Wm. Huddesford, keeper of the Aſhmolean muſeum, who ſubjoined two indices, one according to Liſter's diſtribution of the ſhells, the other after that of Linnæus. This edition differs from the former principally in containing ſeveral plates on one page, the whole amount is 1085, comprehending altogether 1153 ſhells, excluſive of the foſſils and anatomical ſubjects; ſeven of the plates, however, which appeared in the original work are omitted in this edition.

After this period, and previous to the work of Rumphius, the firſt edition of which appeared in 1705, the names of Fehr, Normann, Schelhammer, and others, are recorded as contributors to the elucidation of conchology, yet their productions are to be regarded only as ſubſervient to more extenſive and important inveſtigations. Fehr wrote a diſſertation on the argonauta argo, which was printed in "Eph. Acad. Nat. Cur." A. D. 1686. Normann, in the ſame year, gave an anatomical diſſertation on the purpura, which was publiſhed at Upſal. The obſervations of Schelhammer, publiſhed in "Eph. Acad. Nat. Cur," relate to the ſubject of freſh water ſhells. Brachius alſo treats of the ova of ſome ſpecies of oſtrea. "Le Cabinet de la Bibliotheque de Saint Genevieve," of Du Molinet contains a few figures of ſhells. In the Philoſophical Tranſactions, vol. xvii. is a communication on the ſubject of ſhells, addreſſed to Dr. Liſter, by Mr. Baniſter who reſided many years in Virginia, and in the ſame volume is a deſcription of certain ſhells found in the Eaſt Indies by Witzen, but theſe are confeſſedly too imperfect to merit further mention. Sir Robert Sibbald alſo publiſhed ſome curious papers on teſtaceology about this time, but his ſyſtem, and beſt production, on this ſubject, have been already noticed. Ericus, in a diſſertation entitled "Conchæ anatiferæ vindicatæ," refutes the abſurd tale of the Bernacle geeſe hatching in thoſe ſhells as related by ſir Robert Moray. Leeuwenhoek publiſhed ſeveral treatiſes on the anatomy or inteſtinal ſtructure of ſhells. Leigh notices a few of the Britiſh ſhells in his "Natural Hiſtory of Lancaſhire;" and Wallace an inconſiderable number in his "Account of the iſlands of Orkney." The works of Petiver, which are diſperſed in the 22d, 23d, and 24th volumes of the Philoſophical Tranſactions, and his "Gazophylacium Naturæ et Artis," may be conſulted with advantage, being referred to by Linnæus and other late conchologiſts. This brings us to the time of Rumphius.

The popular work uſhered into the world under the immediate patronage of the liberal collector laſt mentioned, claims particular notice. This valuable acquiſition, for ſo it muſt be conſidered, bears the title of "Amboinſhe Rarite it Kamer," the "Rarity Chamber of Amboyna;" and contains an account of the more remarkable natural curioſities in his muſeum, the productions of Amboyna, where they had been collected chiefly by Rumphius himſelf. The deſcriptive matter is from the pen of M. Schein Voet, and the plates are engraven in a bold ſtyle from the deſigns of Madame Merian. Of ſixty plates with which this work is embelliſhed, no leſs than thirty-three are devoted to the ſubject of ſhells, the total number of which amounts to about four hundred ſubjects, and many of theſe were of great rarity and price in thoſe days. The paſſion for collecting and forming cabinets and muſeums began at this period to be very prevalent in Holland, from whence it afterwards extended over the other parts of Europe. The collection of Rumphius was an object worthy of emulation, and many wealthy individuals endeavoured to excel in this purſuit. The forming a collection of rarities at that period was conſidered a ſerious undertaking. Articles of rarity of this deſcription will always obtain a conſiderable price. It is related as a matter of aſtoniſhment that Rumphius himſelf informs us a ſhell deſcribed in his work coſt no leſs than five hundred florins. The ſum is great, yet there are few cabinets of any note that do not include articles of equal or much ſuperior value.

Lyonet eſtimated the price of his famous " cedo nulli" far higher, namely, 100*l.* ſterling; and many inſtances of great prices being paid for ſuch objects might be adduced. There are two editions of the work of Rumphius, the firſt written in the Dutch, the other in the German language.

Levin Vincent was one of the moſt diſtinguiſhed Dutch collectors. Contemporary with Rumphius, he has left us a deſcription of his muſeum, dated 1706, and bearing the title of " Wondertooneel der Nature." This work was printed at Amſterdam entirely in the Dutch language; the various objects are repreſented as they were placed in caſes, drawers, or boxes, in a confuſed manner in the muſeum; among which we recognize a prétty conſiderable number of ſhells. An abridged account of the muſeum, with impreſſions of the ſame plates, was publiſhed afterwards.

The papers of Reaumur, inſerted in the memoirs of the French academy, between the years 1709 and 1717, deſerve the attention of the conchologiſt; they relate, for the moſt part, to the formation, growth, and motive powers of teſtaceous animals. The natural hiſtory of the pinnæ, and the formation of pearls, are amply treated of in a memoir which appeared in the volume for 1717.

In 1710 Fridericus Ruyſch publiſhed a deſcription of his muſeum at Amſterdam, entitled " Theſaurus Animalium primus:" it relates only in a partial degree to ſhells, the figures of which are grouped with coral and other ſubſtances as they ſtood in his muſeum.

Morton, the natural hiſtorian of Northamptonſhire, deſcribes many ſhells, for the figures of which he refers to Liſter. This work was publiſhed in folio in 1712.

Among the plates illuſtrative of various curious ſubjects, contained in the muſeum of Gottwald of Dantzic, dated 1714, forty-three are appropriated to ſhells. Few of the original copies are complete; that poſſeſſed by ſir Joſeph Banks is perfect.

Three plates of ſhells are to be found in the botanical work of Barrelier, edited by the elder Juſſieu, which appeared in 1714; and the like number in the " Rariora Muſei Beſleriani" of J. H. Lochner, publiſhed two years after. The " Amphitheatrum Zootomicum" of M. B. Valentini, brought forward at Frankfort in 1720, includes many extracts from foregoing authors, and ſome plates relative to ſhells, but which are not conſidered to poſſeſs any merit of originality, or execution. Bradley, in his philoſophical account of the works of nature, touches on the ſubject of teſtaceology though in a ſuperficial manner.

The valuable work of Car. Nic. Langius, " Methodus nova Teſtacea Marina in ſuas Claſſes, Genera, et Species diſtribuendi," was publiſhed in quarto at Lucerne, in 1722. To the writings of this able naturaliſt Linnæus ſtands highly indebted. " He is an author (ſays Dr. Maton) not undeſerving the title of a ſcientific one, and whoſe ſyſtem, ſo far as marine teſtacea are concerned, and of theſe alone he treats, certainly glances at the great clue to ſimplicity, which was afterwards ſo ſucceſsfully and admirably ſeized by the great reformer of natural hiſtory in general."—" He is the firſt whoſe generic characters are founded on commodious diſtinctions; the aperture of univalves, and the hinge of bivalves, being particularly conſidered. Theſe diſtinctions are not allowed their due importance throughout, for the contour of the ſhell is, in many inſtances, made the excluſive baſis of the definition, and the adoption of this naturally led, as in other ſyſtems, to a moſt inconvenient and perplexed multiplication of genera. The parts, claſſes, and ſections, alſo are far from being well conceived, and embarraſs rather than aſſiſt the inveſtigation of the other diviſions." After peruſing theſe general ſtrictures the curious reader may be deſirous of acquiring ſome knowledge of this author's ſyſtem. We are inclined to think it entitled to rather higher praiſe.

Langius divides ſhells into three parts. 1. Teſtacea marina univalvia, non turbinata. 2. Cochleæ marinæ. 3. Concha marina.

His firſt part is ſubdivided into two claſſes. Claſs 1. Teſta marina univalvia non turbinata, et in ſe non contorta. Claſs 2. Teſta marina univalvia, non turbinata in ſe contorta, ita, ut eorum ſpiræ non promineant. His cochleæ marinæ, or part. 2. conſiſts of ſix claſſes, *viz.* 1. Cochleæ marinæ longæ. 2. Cochleæ canaliculatæ. 3. Cochleæ marinæ ore et mucrone ſimul elongatis, prima ſpira notabiliter ventricoſa. Buccina. 4. Cochleæ marinæ ore, et mucrone elongatis, prima ſpira notabiliter anguſtiori quam in Buccinis. Strombi. 5. Cochleæ marinæ ore admodum brevi mucrone inſigniter elongato. Turbines. Trochi. 6. Cochleæ marinæ breviores ore et mucrone contractis. The third part, or conchæ marinæ, conſiſts of three claſſes. 1. Conchæ æquilateræ. 2. Conchæ inæquilateræ. 3. Conchæ anomalæ ſ. Valvis inæqualibus. The claſſes are divided into ſections, the diſtinguiſhing characters of which are taken from the moſt prominent features of the various tribes of ſhells, as the form of the ſhell itſelf, the ſtructure of the aperture, the canaliculation, or lip, &c. in univalves; and the ſhape of the valves, their diſſimilarity, the beaks, hinge, teeth, &c. in bivalves. The ſections are divided into many genera, the firſt claſs containing ſeventeen, the ſecond fifty, and the third forty-three. Many of the genera of old writers are divided, and oftentimes not injudiciouſly, into two or more genera, to which new names are aſſigned, that Linnæus and later writers have adopted. We cannot further digreſs on the merits of this work, but as a ſyſtem recommend it to the attention of the curious conchologiſt.

In the work, entitled " Oud en Nieuw Ooſt-Indien," by Valentyn, are ſixteen plates of Eaſt Indian, or Amboyna ſhells. This bears date Amſterdam 1724 and 1726, having been publiſhed in folio parts. Thoſe plates were afterwards ſold ſeparately with deſcriptions; the new edition of the plates appeared in 1754.

" Sloane's Hiſtory of Jamaica" is a valuable work, and relates to conchology, among a miſcellaneous variety of other departments of natural hiſtory. He was the firſt perſon who viſited the Weſt India iſlands for the ſole purpoſe of inveſtigating their natural productions, and his plates and deſcriptions relate of courſe to many ſubjects not before known. His diſcoveries were ſubmitted to the public in 1725.

In the following year, John Chriſt. Kundmann publiſhed his " Promptuarium rerum naturalium et artificialium," &c. in quarto. He propoſes three principal claſſes for the arrangement of ſhells. Claſſis 1. Teſtacea univalvia non turbinata. Claſſis 2. Teſtacea bivalvia. Claſſis 3. Teſta univalvia turbinata; each of which is divided into a number of genera, ſomewhat after the method of Buonanni.

A new arrangement of ſhells, by John Erneſt Hebenſtreit, appeared at Leipſic in 1728; " Diſſertatio de Ordinibus Conchyliorum methodica Ratione inſtituendis." The limits of our obſervations will not permit us to enter minutely into this methodus teſtaceorum. The ſyſtem of this author comprehends ſeveral principal claſſes: namely. Claſſis 1. Univalvia irregularia. Claſſis 2. Univalvia regularia, quæ ſpira carent. Claſſis 3. Univalvia regularia, quæ ſpira gaudent magis turbinata, turbine per totum excurrente. Claſſis 4.

De vertice tantum turbinata, ore per totum hiante, turbinibus obliqué flexis. Claſſis 5. Univalvia, vertice tantum turbinata, ore per totum hiante, ſpiris circa centrum flexis. Claſſis 6. Minus turbinata ſpira unica brevi. Claſſis 7. Bivalvia valvis per ginglymum connexis. Claſs 8. Bivalvia per ginglymum cohærentia. The outline of his arrangement may be collected from his definition of the claſſes. His families, or ſubdiviſions, and genera are numerous, and are characterized by the figure of the ſhell, the aperture, hinge, and other remarkable particulars. Dr. Maton accuſes this writer of having introduced an uſeleſs, if not unphiloſophical diſtinction, between teſtacea and conchylia. Bergen previouſly makes the ſame objection. "Cl. auctor diſtinguit inter teſtacea et conchylia, et notionem generaliorem tribuit prioribus, quia et malacoſtri, et oſtracodermata; conchylia vero ſola oſtracodermata ſub ſeſe comprehendunt, ſed non magni momenti mihi videtur hæc diſtinctio, ſi viciſſim conſidero et perpendo ſub notione teſtæ et duram et mollem teſtam intelligi poſſe."

The "Diſſertatio Phyſica de Polythalamiis, nova teſtaceorum claſſe," of Breynius, comprehends an arrangement of recent and foſſil ſhells, but the chief merit of the work is allowed to conſiſt in the more exact definition this writer affords of the *belemnitæ*, *ammonitæ*, and *orthoceratitæ*, than had before appeared. Of the orthoceras tribe, he deſcribes eight diſtinct ſpecies, the two others are treated leſs copiouſly. His claſſification of recent ſhells is far from perſpicuous. This was publiſhed in quarto in 1732.

About this period, the attention of many ingenious writers was directed to the inveſtigation of the teredo, or ſhipworm, then, as it was believed, very recently imported from warm climates into Europe; it was firſt obſerved in Holland. The firſt alarm was given by the perſons appointed to take care of the dykes, who perceived, that the piles which were of the hardeſt oak, and had been placed to defend the low countries from the incurſions of the ſea, were eaten through in a few months. The damage occaſioned was immenſe, and the people of Holland thrown into the utmoſt conſternation, till remedies were diſcovered to prevent the evil. Among the writers on the ſubject, are Valliſneri, Rouſſet, Patoneus, Belkmeer, Maſſuet, and Sellius, the laſt of whom particularly diſtinguiſhed himſelf by his work entitled, "Hiſtoria Naturalis Teredinis ſeu Xylophagi Marini."

Du Hamel, in a paper inſerted in the "Memoirs of the French Academy," in 1736, treats on the purpura of the ancients. The work of Swammerdam, "Biblia Naturæ," appeared in 1737, and will be found to contain much curious matter, and anatomical reſearch into the nature of teſtaceous animals. In 1739, the work of James Plancus, "De Conchis Ariminenſibus minus notis," appeared in Venice. This relates principally to the minute ſhells found at Rimini in the Adriatic ſea. Some of the microſcopic ſhells deſcribed by this author, very much reſemble the cornu ammonis. A ſecond edition was publiſhed in 1748, and another at Rome in 1760.

Gualtieri's work on ſhells is a ſtandard book of reference, and as ſuch is well known. This is entitled "Index Teſtarum Conchyliorum quæ adſervantur in Muſeo Nicolai [illegible]" &c. It was publiſhed in Latin at Florence, in 1742, and contains 110 plates of ſhells; the figures of the univalves in which are ſingularly placed on their ſummit; they are notwithſtanding tolerably correct: the deſcriptive matter is leſs intereſting. This author exhibits a ſyſtem of ſhells compoſed by Tournefort, the celebrated botaniſt, long before this time, from manuſcripts on the ſubject that had been preſented to him by profeſſor Targioni. This arrangement is valuable, and highly worthy the peruſal of the inquiſitive conchologiſt. The Linnæan ſtudent, in particular, will perceive that to Tournefort, as to Langius, he is indebted for ſome of the lateſt amendments of the Linnæan ſyſtem, and for many of the ſubdiviſions and terms in preſent uſe.

"La Conchyliologie" of D'Argenville is a voluminous work, and contains a vaſt number of excellent deſcriptions, and many figures. The firſt edition of this work appeared anonymouſly, under the title of "L'Hiſtoire Naturelle éclaircie dans deux de ſes parties principales, la Lithologie, et la Conchyliologie," &c. in 1742; and a ſecond edition, conſiderably augmented, in 1754. The laſt edition was publiſhed in the year 1780, with many additions, corrections, improvements, and a ſeries of plates containing about 2000 figures, by M. Favanne de Moncervelle and his ſon.

The name of Bartram occurs to a paper in the Philoſophical Tranſactions, vol. xliii. A.D. 1744, entitled "Obſervations concerning the Salt-marſh Muſcle, the Oyſter-banks, and Freſh-water Muſcle of Penſylvania," illuſtrated with figures. A copious account was alſo given about this time by Needham, of the lepas anatifera. The "Teſtaceo-Theologia" of Leſſer, is embelliſhed with 137 figures of ſhells, and abounds with phyſiological and anatomical obſervations on the ſtructure of theſe teſtaceous animals.

Some mention is made of ſhells in Dr. Charles Smith's "Hiſtory of the Counties of Waterford, Cork, and Kerry," A.D. 1745—1756. Two papers, one relating to mytilus lithophagus, and the other to pholas puſilla, are inſerted in vol. xlv. and vol. lv. of the Philoſophical Tranſactions. In ſir John Hill's "Hiſtory of Animals," are an arrangement of ſhells, and ſome figures; it appeared in folio in 1752.

The firſt work of Klein's that claims mention in this place is his "Deſcriptiones Tubulorum Marinorum," containing nine plates, which chiefly repreſent different ſpecies of belemnitæ, with various kinds of recent ſhells, as ſolenes, dentalia, &c., and are introduced in order to complete his arrangement of the tubular coverings of animals. But the principal production of this writer is his "Tentamen Methodi Oſtracologicæ, ſive Diſpoſitio Naturalis Cochlidum & Concharum, in ſuas claſſes, genera, & ſpecies," &c., printed at Leyden in 1753. It has been objected againſt this work that the general diviſions forming parts, ſections, claſſes, and genera, are too numerous; and what is worſe, that ſpecies are conſtituted, in ſome inſtances, without being referable to any genus, and that, in one of the parts, there is a ſolitary genus without any claſs. (Dr. Maton)—"Claſſes, genera, & ſpecies nimium, ut mihi videtur, multiplicavit: quæ ſæpe ſunt variationes ſpecierum, ſpecies vocavit; quæ ſunt ſpecies, generum nomine inſignivit; & ex generibus quibuſdam claſſes condidit," &c. Bergen.

The outline of an arrangement formed by a naturaliſt ſo eminent as Klein ſhould not be paſſed over unnoticed. All ſhells are divided by this writer into four principal parts, in the following manner:

Pars 1. *Cochlides,* canales teſtacei, circa principium tenues & clauſi, in gyros gradatim vaſtiores conſtanti ratione circumacti.

Pars 2. *Conchæ.* Teſtæ vaſculorum inſtar explanatæ & concavæ, variorum animalium exſanguium habitacula, teſtarum numero a ſe invicem differentes.

Pars 3. *Polyconchæ,* quæ pluribus valvulis quam duabus gaudent.

Pars 4. *Niduli teſtacei*, teſtacea animalium domicilia in forma niduli ſeſſilis catervatim plerumque corporibus marinis ſuperſtructa.

The *cochlides* comprehend two ſections, "cochlis ſimplex, and cochlis compoſita:" theſe are again ſubdivided into families, and laſtly into genera. Among the ſhells included in the firſt of theſe, we find the nautilus, cornu ammonis, neritæ, auris marina, trochus, ſtrombi, turbines, and the buccinum; and in the ſection cochlis compoſita, the bulla, porcellana, and murex. The ſecond part, *conchæ*, of this author is compriſed in three ſections "monoconchæ, diſconchæ æquales, and diſconchæ inæquales." Among the firſt of theſe, we obſerve the patella, in the ſecond, the oſtrea and ſpondylus, and in the third, the terebratula. Part 3, or *polyconchæ*, conſiſts of "concha anatifera." Part 4, comprehends the balani under the title of "monolopus and polylopus;" and as an appendix to part 4, and as a fifth part, the "echinus marinus, and tubulus marinus."

Although the diſtribution of ſhells after the manner of Klein does not meet our ideas of a correct methodical arrangement, it is but candid to ſay, that many of the genera he propoſes have been rejected by later writers without ſufficient conſideration, and others derived from his labours without acknowledgment. Let us pauſe and candidly examine this arrangement, and we ſhall perceive that not only Linnæus himſelf derived very conſiderable aſſiſtance from his work, in the latter editions of the "Syſtema," but that many of the ſuppoſed new genera of the French writers, in the preſent day, are drawn from this very ſource. This work contains twelve plates, and beſides the ſyſtem above noticed, comprehends a diſſertation on the form, growth, and colour of ſhells "De Formatione, Cremento et Coloribus Teſtarum."

The "Conſpectus Sciographicus Teſtaceorum" of J. H. Cohauſen, was printed at Frankfort about the year 1750.

In 1755, a work of conſiderable importance, the production of Nicholas George Geve, an eminent painter, appeared in quarto at Hamburgh, under the title of "Monatliche beluſtigungen im reiche der Natur, an Conchylien und Seegewächſen," or "The monthly amuſement of Shells and Sea Productions." This publication came out in parts, and was favourably received, but being pirated was diſcontinued. The total number of plates publiſhed appears to be 33, the figures in which amount to 434.

The memoirs of the French Academy for 1756, contain a curious paper on the characters of ſhells, in which fourteen genera are deſcribed, founded on the nature of the animal inhabitants; this bears the title of "Obſervations qui peuvent ſervir à former quelques charactères des coquillages," and is from the pen of Guettard; another paper alſo on the ſubject of conchology, "Sur le Rapport qu'il y a entre les Coraux et les Tuyaux marins, et entre ceux-ci et les Coquilles," from the ſame writer appears, in the Memoirs of that Academy for 1760, to which five plates of ſerpulæ, dentaliæ, &c. are annexed. Guettard was beſides theſe the author of two or three ingenious tracts on the ſame ſubject, the titles of which do not immediately occur to us. The "Diſſertatiuncula de Cornu Ammonis nativo Littoris Bergenſis in Norvegia," produced in 1757, and "De Tubulis vermicularibus cornu ammonis referentibus," bearing date 1761, are both the performances of J. F. Hoffman, and appeared originally in the Tranſactions of the Electoral Academy of Mentz. Theſe, as their titles imply, relate to a ſuppoſed diſcovery of ſome recent ſhells of the cornu ammonis tribe, but which, in reality, are only of the nautilus kind, though bearing a remote reſemblance to the foſſils known by the title of ammonitæ. Shells ſimilar to thoſe had been before obſerved by Plancus. Another paper in the ſame volume as that laſt mentioned is from this writer, and bears the title of "De Concha Sphærica fluviatili, alata ex badio et nigro colore variegata."

"The Civil and Natural Hiſtory of Jamaica," publiſhed in London in 1756, by Dr. Patrick Browne, contains a ſcheme of ſhells, which, conſidering the ſtate of the ſcience of conchology at that period, is leſs ſatisfactory than might be expected. Shells are divided by this author into three claſſes, *univalvia*, *bivalvia*, and *plurivalvia*. The characters of his ordines are taken, in the univalves from the hollow of the ſhell being non-ſpiral, or ſpiral, and the ſituation, and form of the aperture, and the lip; in the bivalves from the ligament of the hinge, and the teeth; and in the plurivalves from the connecting ligament of the valves.

The "Opere Poſtume" of count Joſeph Ginanni of Ravenna, contains a deſcription of the maritime, marſh, and terreſtrial ſhells of the territory of Ravenna, after a ſyſtem ſomewhat ſimilar to that of Buonanni. The firſt of theſe tribes is illuſtrated by thirty-one plates, the ſecond by four, and the third by three. The deſcriptive matter is in the Italian language. It was publiſhed in folio, in 1757.

Adanſon's "Hiſtoire Naturelle du Senegal," was publiſhed at Paris in 1757. This uſeful work contains a new arrangement of conchology, and a ſeries of about four hundred figures of ſhells, with the animals appertaining to the principal families. This production of Adanſon's is in much eſteem with the continental naturaliſts.

The books of Baſter, "Opuſcula ſubſeciva, obſervationes miſcellaneas de animalculis," &c. dated Harlemi, 1759, 1760, 1761, 1762, and two 1756, afford the curious reader much information relative to the anatomical, and phyſiological nature of teſtaceous as well as cruſtaceous animals. In theſe we find the propagation, and ovaria of ſhell fiſh in general, treated of in an ample manner. A tranſlation of the author's diſſertation on the teredo navalis appears in the Philoſophical Tranſactions.

A monographia on helix decollata, entitled "Obſervations ſur une eſpece de Limaçon terreſtre dont le ſommet de la Coquille ſe trouve caſſé ſans que l'Animal en ſouffre," by M. Briſſon, is inſerted in the memoirs of the French Academy for 1759.

The teſtaceological labours of the celebrated Linnæus ſhould be particularly adverted to in this place. One of the earlieſt of his productions on this ſubject is the "Fauna Suecica," the firſt edition of which was publiſhed in 1746, and contains an account of ſixty different ſpecies of Swediſh ſhells. His travels in Gothland, "Wäſtgöta reſa, förättad ar 1746," appeared at Stockholm the year after, and though teſtaceology had only partially intereſted the remarks of Linnæus, we are here preſented with a deſcription of ſeveral ſhells obſerved in his journey, and likewiſe a plate including a number of figures, rude indeed in the execution, and ſtill more defective in repreſenting all the univalves as heteroſtrophous ſhells, but valuable as a plate of reference to conchologiſts even at this day, (vide Donov. Brit. Shells, murex deſpectus). The "Muſæum Teſſinianum," publiſhed in 1753, and "Muſæum Adolphi Frid. Sueciæ Regis," in the year following, ſcarcely demand mention as they contain only three ſpecies of the ſhell tribe. In the deſcription of another muſeum, that of the queen of Sweden, "Muſæum Ludovicæ Alricæ Reginæ;" Linnæus poſſeſſed a more favourable opportunity of treating on teſtaceology, as her majeſty's collection was particularly rich in ſhells; this work deſcribes 434 ſpecies of ſhells, and ſome do not ſcruple to affirm that it is the beſt of the

Linnæan productions on the ſubject of teſtacea; it appeared in 1764. In the interval between the times in which the two laſt mentioned works were publiſhed, Linnæus brought out a ſecond edition of the "Fauna Suecica," in which the number of ſhells deſcribed was augmented from ſixty to eighty-nine ſpecies.

The "Mantiſſa Altera" contains thirty-five ſpecies not deſcribed in the other works already mentioned. The "Fundamenta Teſtaceologiæ" is one of his lateſt tracts, and is to be found among the "Diſſertationes Academicæ."

Theſe are valuable books in a limited view, but the claſſification of ſhells in the "Syſtema Naturæ" from the nature of the undertaking is to be conſidered the moſt general of all the Linnæan writings on the teſtacea. Between the year 1735, in which that work firſt appeared, and 1767, the Syſtema paſſed through no leſs than twelve editions, in all which a progreſſive improvement, and nearer approach to perfection are manifeſted, and in no one department is this more unequivocally ſhewn than in the methodical diſtribution of the ſhells.

An opinion is pretty generally prevalent that leſs attention was devoted by Linnæus to the hiſtory and arrangement of the teſtacea, than any other order of nature; and that he even thought them unworthy of becoming objects of ſcientific arrangement. Theſe points have been conteſted. The truth however ſtill appears to be, that Linnæus had not really beſtowed much critical attention on this ſubject. We can eaſily imagine that the mind of Linnæus might fluctuate between the propriety of eſtabliſhing his conchological ſyſtem upon the characters of the animals, and the difficulty, if not impoſſibility, of accompliſhing it, and that in this ſtate of indeciſion the ſhells themſelves were, in a great meaſure, diſregarded by him. When therefore the completion of the Syſtema required that ſome attention ſhould be paid to teſtaceology, he was unprepared, and reſorting to the authorities of others, compriſed this department in the ſmalleſt compaſs poſſible, more with the view of filling up a chaſm, which the omiſſion of a tribe ſo generally admired would occaſion, than from any idea of elucidating the ſubject.—A ſimilar reaſon is well known to have operated on the mind of Linnæus, with reſpect to his ſyſtem of mineralogy, which was added principally, in order that this work ſhould comprehend the three kingdoms of nature.

Whether this concluſion be correct or otherwiſe, one fact inferred is very obvious, that the early attempts at the claſſification of ſhells, which the Syſtema preſents, do not afford that happy reſult to be expected from the induſtry, and ſuperior genius, of Linnæus.—It is time we ſhould lay aſide the trammels of ſervile adherence, and ſpeak decidedly:—thoſe early attempts of this celebrated writer we do not ſcruple to ſay, if examined with candour, will be found only a ſlight and ill conceived compendium of what has been handed down to us by antecedent writers; and which, if he had more cloſely imitated in the outſet, as he afterwards found it incumbent upon him to do, would have reſcued his reputation as a conchologiſt from conſiderable blame. Can we for a moment, dazzled with the ſplendor of a name, however dignified, deny that merit which is ſo conſpicuouſly prominent in the claſſifications of preceding writers, and attribute all the credit of reducing ſhells into method and order to the genius of Linnæus? or can we, after duly eſtimating the teſtaceological labours, even of Geſner, Aldrovandus, and Major, we would almoſt ſay of Ariſtotle, be diſpoſed to commend this naturaliſt for overwhelming their arrangements in one common ruin; aboliſhing at the leaſt forty excellent genera eſtabliſhed by the different writers, and in lieu of thoſe preſenting us with eight genera for the reception of the whole teſtaceous tribe! Yet ſuch is the fact, the only genera of ſhells, included in the firſt editions of the Syſtema, are *cochlea*, *nautilus*, *cypræa*, *haliotes*, *dentalium*, *concha*, and *lepas*.

Linnæus was himſelf embarraſſed in the diſtribution of ſhells into ſuch a ſmall number of genera; he even found it impracticable, and hence we perceive, in the later editions of that work, their number progreſſively augmenting till, in the laſt publication of the Syſtema, they were multiplied to thirty-five. Thus from time to time. as his acquaintance with ſhells became more general, we ſee him deriving new ſtrength and ſupport, in the aid of his own ſyſtem, from thoſe very ſources which, in the firſt inſtance, he too incautiouſly attempted to ſubvert; the genera afterwards admitted into the Syſtema, even to thoſe laſt adopted, being with ſcarcely an exception to the contrary, drawn from the labours of naturaliſts who wrote in the century preceding, or much before.

It is an opinion likewiſe founded in error, that we are indebted for the outline of this teſtaceological ſyſtem (conſidered in its moſt improved ſtate) to the native genius of Linnæus. No one will hazard the aſſertion, we ſhould conceive, who is in the ſlighteſt degree acquainted with the writings before-mentioned. His primary diviſions were ready formed to his hands. Let us examine further: in the outline of his ſyſtem, he divides all teſtaceous bodies into three principal orders, *multivalve*, *bivalve*, and *univalve*. If we take the univalves of Ariſtotle (retained by later writers under the title of turbinata), the bivalves of all writers, from the time of Ariſtotle incluſively, and the plurivalves of Major, invert their order, and we at once poſſeſs the complete outline of the ſyſtem attributed to Linnæus. Or we may refer with equal certainty to the principles of Major's ſyſtem alone, publiſhed ſixty years before the firſt edition of the Syſtema made its appearance, in which this inverted arrangement occurs preciſely, univalvia, bivalvia, and plurivalvia. Linnæus, therefore, it may be fairly inferred, was not the inventor of the ſyſtematic outline aſcribed to him, for it was long in uſe before his time.

If we next deſcend from the primary diviſions, or orders of the Linnæan ſyſtem to his genera, theſe ſtill are to be found in the ſame, or other early writers, perhaps a ſolitary tranſpoſition (as in conus and ſtrombus) excepted, and furthermore even under the very names he aſſigns to them. His obligations to the labours of Langius are too obvious to be concealed. But although, in this particular, Linnæus has only the more moderate merit of adopting, inſtead of inventing the outlines of his ſyſtem, he is to be applauded for having condeſcended to ſelect what it appears he thought, on mature deliberation, ſuperior to his own. And this, in our idea, was ſo far commendable, that we regret he had not been influenced by the ſame opinion in his firſt views of a teſtaceological claſſification. Linnæus had aſſuredly much diffuſe and ambiguous matter to wade through in his inveſtigations of former ſyſtems in general, and his ſelections were at length both clear and judicious, though ſtill ſuſceptible of much improvement. We are alſo to give the celebrated naturaliſt his full ſhare of credit for having ultimately improved, and more accurately defined, the characters of the reſpective genera which he has adopted, than any of his predeceſſors; the characters of his ſpecies alſo, generally ſpeaking, are not to be excelled for expreſſive ſimplicity and conciſeneſs. He may be truly ſaid to have reformed the language of natural ſcience, before much too vague, by the introduction of that peculiar brevity of ſtyle, ſo extremely uſeful in the nice diſcrimination of natural objects, and which he ſeldom fails to apply with the happieſt poſſible effect.

The merits of Linnæus, as a great naturaliſt, will ſhine with undiminiſhed ſplendour, diveſted of its meteorous luſtre: the world feels grateful to his genius. But nothing leſs than an acquieſcence unworthy of his character, and of ourſelves, can lead us to conclude he was equally ſucceſsful in all his endeavours to develope the myſteries of nature. For our own part, attached to no particular ſyſtem, we would rather "ſtem the torrent alone, than glide down the ſtream with many," in contradiction to the evidence of our own mind; we are the friends of Linnæus,—and of truth. We are perſuaded, furthermore, that what the reſult of calm inveſtigation approves, muſt redound more to the credit of Linnæus than that implicit obedience which bows down our reaſon, and rejects inquiry. The celebrity ſo deſervedly acquired by his writings in general, has ſtamped his ſyſtem of teſtaceology with repute. Its reputation induces us to examine it with more than ordinary attention. It is in England, what that of Lamarck's is in France, and ſome others in different parts of Europe; the ſyſtem beſt known, and the moſt admired. We ſhall for this reaſon take a comprehenſive view of the whole, regarding every genus ſeparately in the ſame order as Linnæus places them; and offering, as we proceed, a few curſory remarks on each, with a view to enable the common reader to form his own opinion, and judge for himſelf of the comparative excellence or ſuperiority of the Linnæan ſyſtem of teſtaceology.

The primary diviſions of this ſyſtem, in the lateſt edition of the "Syſtema Naturæ," as before obſerved, conſiſt of three orders, *multivalve*, *bivalve*, and *univalve*, each of which is ſubdivided into genera. The *multivalves* contain the chiton, lepas, and pholas; the *bivalves*, mya, ſolen, tellina, cardium, mactra, donax, venus, ſpondylus, chama, arca, oſtrea, anomia, mytilus, and pinna; and the *univalves*, argonauta, nautilus, conus, cypræa, bulla, voluta, buccinum, ſtrombus, murex, trochus, turbo, helix, nerita, haliotis, patella, dentalium, ſerpula, teredo, and ſabella.

Genera.

Chiton. Animal a doris. Shell conſiſting of ſeveral tranſverſe incumbent valves, diſpoſed in a longitudinal ſeries down the back.

Our knowledge of this genus was very confined till within the laſt few years; ſo lately as the period in which the tenth edition of the Linnæan "Syſtema Naturæ" appeared, only four of its ſpecies were known, at leaſt no greater number is deſcribed by that writer. To the valuable work of Chemnitz, we are indebted for the addition of thirteen other ſpecies; to Schröetter, for three or four; and to Pennant for nearly an equal number; all of which are included in the laſt edition of the "Syſtema Naturæ à Gmelin," with a few others, amounting altogether to twenty-eight ſpecies. Though we are pleaſed to ſee ſuch a number of this curious genus, concentrated in one point of view, we cannot avoid expreſſing a wiſh that ſome few of the ſpecies at leaſt were better explained, thoſe eſpecially which are confined to the continental muſeums; one, if not more of the ſpecies deſcribed by Pennant, is confeſſedly erroneous.

Lepas. Animal a triton. Shell affixed at the baſe, and conſiſting of many unequal valves. Linn.

The propriety of ſeparating the balani, or acorn ſhells, from the anatiferæ, or as vulgarly denominated the "gooſe bearing ſhell," has never yet been queſtioned by any well-informed naturaliſt, although from motives of caution we, have, with others, ſubmitted to the genus eſtabliſhed by Linnæus, till our reaſons for diſſenting from his authority (and which the Linnæan ſtudent might deem an innovation) could be explained in its proper place.

We were always at a loſs to ſee the true reaſon that could induce Linnæus to place theſe two very oppoſite natural families together; the only juſtification ſeems to be, that the animals of the two genera (for ſo we ſhall denominate them) are of the triton kind, and that no other multivalve ſhells are inhabited by this kind of animal, that of chiton being a doris, and of pholas an aſcidia. At the ſame time, it will be remembered, that animals of the ſame kind inhabit ſhells of very different genera, and that it is therefore no argument, becauſe all of the Linnæan genus lepas are inhabited by the triton, that they muſt be of the ſame genus. We cannot ſurely infer this from any ſimilitude in the ſtructure of the two kinds of ſhells. What, for inſtance, can be more diſſimilar than the firſt very eſſential particular in which theſe ſhells diſagree, namely, the manner in which they are affixed; the balani cemented immoveably by its baſe to the rocks, looſe ſtones, or any other extraneous ſubſtances, while the anatiferæ are connected to, and ſupported at their baſe by a tendinous tube, which being of a flexible nature, allows the animal an opportunity of writhing or turning in any direction in queſt of food. Again, the very ſtriking circumſtance, which Linnæus had always himſelf regarded as of the firſt conſequence in an arrangement of ſhells, the preſence and abſence of the operculum: in the anatiferæ, there is no operculum whatever; while, in the balani, that part conſtitutes one of the principal features of the ſhell; it is even the ſtructure, rugoſity, or other peculiar circumſtances obſervable in this part, that afforded Linnæus the beſt of his characters, in defining the ſpecies of this family. This operculum or lid of the balani conſiſts of four or ſix valves. The above characters are ſo obviouſly diſtinct, that it may be almoſt conſidered needleſs to advert to the form of the two ſhells, though in this alſo they differ moſt eſſentially; the anatiferæ are wedge-formed, and conſiſt of five or more unequal valves; the balani of ſix valves, and the general form of the ſhell is ſubconic.

Pholas. Animal an aſcidia. Shell bivalve, divaricated, with ſeveral leſſer, differently ſhaped, acceſſory ones at the hinge; hinges recurved, and united by a cartilage; an incurvated tooth in the inſide beneath the hinge.

Theſe ſhells were formerly called piddocks by the Engliſh; they are found below high-water mark burrowed in hard clay, lime-ſtone, or ſometimes free-ſtone, and alſo wood; which they perforate in their younger ſtate, and as they increaſe in ſize enlarge their habitations. The animal is ſomewhat cylindrical in form, and is furniſhed with two orifices or openings, capable of elongation in the manner of a proboſcis; from one of which, ſuppoſed to be the mouth, it has the faculty of ſquirting water. The phoſphoreſcent properties of the pholade are very remarkable; it contains a liquor which ſhines with uncommon ſplendour in the dark, and illuminates whatever it touches, or happens to fall upon. This is noticed by Pliny, lib. ix. c. 61, and M. Reaumur has alſo written copiouſly on this ſubject, in the Memoirs of the French Academy, for the year 1712.

Only twelve ſpecies of this genus are deſcribed in the Gmelinian Syſt. Nat. The pholades were placed by Linnæus among the bivalves.

Mya. Animal an aſcidia. Shell bivalve generally gaping at one end; hinge, with a ſolid, thick, patulous tooth, or ſeldom two, and not inſerted in the oppoſite valve.

Many of the ſhells in this genus were arranged with the muſcles till Linnæus ſeparated them; Gmelin in the laſt edition of the Syſtema Naturæ deſcribes twenty-one ſpecies of the mya tribe.

The Linnæan myæ conſtitute three diſtinct genera, in the lateſt arrangements of the continental writers, as mya, glycimeris, and vulſella. The mya is diſtinguiſhed by a tranſverſe ſhell gaping at the two ends, and having the ligament within; and one valve furniſhed with a ſingle, compreſſed, roundiſh tooth in the beak, perpendicular to the valve, and having the ligament attached to it. The Linnæan mya truncata is of this kind. In the genus glycimeris the ſhell is alſo tranſverſe, and gaping at both extremities, but the hinge is callous and toothleſs, and the ligament ſituated on the outſide. Vulſella has the ſhell long and ſomewhat equivalve; hinge callous, depreſſed, without teeth, and forming a ſtraight line in both valves; the ligament attached to a roundiſh conic hollow; beaks bent and very ſhort. This laſt genus is cloſely allied in many reſpects to the oyſter.

Solen. Animal an aſcidia. Shell bivalve, oblong, open at both ends; hinge with a ſubulate reflected tooth, often double, and not inſerted into the oppoſite valve.

Gmelin deſcribes twenty-three ſpecies of this genus, ſeveral of which are natives of Europe, where they frequent ſandy ſhores. The Greeks were acquainted with ſome ſhells of this genus, as were alſo the Romans, both of whom valued the fleſh of the inhabiting animal as a dainty. In England they are occaſionally eaten either boiled or fried with eggs, but are not found in ſufficient plenty to be conſidered as an article of food. They are called ſheaths or razor-ſhells in this country.

The Linnæan ſolens are divided by late writers on the continent into three different genera, two of which comprehend the recent kinds, the third is eſtabliſhed chiefly for the reception of ſome foſſil ſhells, ſuppoſed to be of this Linnæan family. Thoſe genera are ſolen, ſanguinolaria, and corbula.

The ſolens, according to thoſe writers, have the ſhells tranſverſe, with the upper and lower margins almoſt ſtraight, with beaks not projecting and gaping at both extremities; and the two valves together furniſh either two or three teeth in the hinge: the ligament of the hinge in this family is placed on the outſide. Sanguinolaria differs in having the upper margin curved, the extremities a little gaping, and two approximate teeth in each valve, which lock into each other when the ſhell is cloſed. Corbula has the valves unequal, ſub-tranſverſe, and regular; with a conic curved tooth in each valve; the ligament of the hinge within, and the inſide of the ſhell marked with two muſcular impreſſions.

Tellina. Animal a tethys. Shell bivalve, generally ſloping on one ſide; in the fore part of one valve a convex, of the other a concave fold; hinge with uſually three teeth, the lateral ones ſmooth in one ſhell.

In the Linnæan ſyſtem the tellinæ are divided into three families, namely, * ovate and thickiſh, ** ovate and compreſſed, *** ſub-orbicular.

A late writer (Dr. Pultney) obſerves, in his "Catalogue of Shells found on the Coaſt of Dorſetſhire," that the tellinæ genus is one of thoſe of which the ſpecies are yet very imperfectly defined, ariſing from the great ſimilitude among them; and from the inſufficient deſcriptions of authors before Linnæus wrote, who, by deducing their characters of the genus, if indeed ſuch they might be called, almoſt wholly from figures, were neceſſarily led to throw together ſhells entirely different, when examined by the characters Linnæus affixed. Thoſe of this great maſter, adds this writer, are yet very imperfect, and ſince the great additions that have been made to conchological ſcience, by later diſcoveries, the whole ſyſtem again wants a total reformation: and the conſtruction of many new genera. The obſervation of this naturaliſt is very juſt; the writers before the time of Linnæus have, with too little caution, derived their characters from figures rather than from the ſhells, a fault we could have wiſhed Linnæus himſelf had more frequently avoided; the tellina of Linnæus is a good genus, but requires to be recaſt; ſome of the ſhells included by this genus have certainly no natural affinity whatever with the others, and the character of the genus itſelf is not laid down with ſufficient preciſion.

Liſter is one of the firſt conchologiſts who deſcribes the tellens with any degree of accuracy: he defines them to be "ſhells ſhaped like wedges," and places them after the pinna, (lib. iii. hd. 2. ſect. 8.) Woodward ſays they have a few teeth on the hinge, and are oblong ſhells, or with the ſides lengthened. Davila comprehends the tellens as a very large family, and includes the ſolens as a genus of them. Da Coſta, in his "Elements of Conchology," attempts to eſtabliſh a family of tellens under the character of the ſhells being more broad than long, rather flat, and the hinge having two teeth ſet cloſe together. This conſtitutes his ninth family of bivalve ſhells; and which he again divides into two genera, the firſt of which he ſtill calls tellina, and the ſecond cunei; his tellinæ are thus defined, "ſhells with ſimilar ſides, whoſe beak and hinge are central;" his cunei "ſhells with diſſimilar or unequal ſides, whoſe beak and hinge are placed near to, or quite at one end."

There is much method, but very little accuracy, or attention to genera, founded on natural affinities and characters, in the arrangements propoſed. It was reſerved for later writers, by a more ſtrict inquiry into the nature and habits of the animals, as well as the nice diſcrimination of characters in the ſhells themſelves, to fix upon deciſive general diſtinctions. It has been diſcovered by Poli, and others of the continental writers, that the animals inhabiting ſome of the tellen tribe are of a different ſtructure from the others; and another objection to the tellinæ, as they now ſtand in that genus, is the diſſimilitude obſervable in the hinge, teeth, and other parts of the ſhell, which Linnæus has himſelf thought eſſential to be regarded in conſtituting genera. The principal of the new genera eſtabliſhed by the lateſt of the French writers are *Cyclas* (cyclade) of Lamarck, and *Pandora* (pandore) of Latreille, the animal of which was previouſly diſcovered by Poli; the ſhell is alſo deſcribed by Linnæus under the name of *Tellina inequivalvis.*

The tellina genus, as now defined, conſiſts of thoſe bivalve ſhells which are orbicular, or tranſverſe, having a regular fold or rumple at the anterior end of the ſhell, with one or two teeth pointed to the beaks; and remote lateral teeth. This will comprehend the true tellinæ. The cyclas is of the Linnæan tellinæ, and is exemplified in the *Tellina cornea* of Linnæus and Pennant. This genus is of a ſub-orbicular form, without a regular fold or rumple at the anterior end; the ligament of the hinge is inflated, and projects out; it has either two or three teeth pointing to the beak, and lengthened lamelliform, or plate-like lateral teeth, which are received into ſockets in the oppoſite valve. The genus pandora, as above intimated, is formed principally of that ſingular ſhell the tellina inæquivalvis. This genus is unequivalve and unequilateral, one valve being convex, the other flat, with flattened ſummit; two unequal diverging teeth at the hinge, pointing to the beak in the upper valve, and two hollows in the lower; ligament within, and the inſide of the ſhell marked with two muſcular impreſſions.

CARDIUM. Animal a tethys. Shell bivalve, nearly equilateral, equivalve, generally convex, longitudinally ribbed, ſtriated, or ſulcated, with the margin dentated. Hinge with two alternate teeth in the middle near the beak, in moſt incurved; lateral teeth remote, and inſerted or locking into the oppoſite.

Forty-nine ſpecies of this genus are deſcribed in the laſt edition of the Syſtema Naturæ.

Da Coſta, in his "Elements of Conchology," propoſes to eſtabliſh a new family of cockles, under the title of pectunculus, whoſe character is a curved or ſemilunar hinge ſet with either two or four teeth. Theſe he divides into three genera. Genus 1. *Pectunculi*, or cockles, with a convex or flattiſh ſhell, of a roundiſh ſhape, with ſimilar or diſſimilar ſides, whoſe beaks are not very prominent, and curve much upwards towards the hinge; they are the *Chamæ* of Argenville and Gualtieri; and do not belong to any particular genus in the Linnæan ſyſtem, but are diſperſed throughout his bivalves, and are only mentioned here to introduce the two next genera. Genus 2. *Cordiformes*, or heart-ſhaped cockles, whoſe beaks are not very prominent, and curve up greatly towards the hinge, thereby forming a figure perfectly like a heart as vulgarly painted. Theſe are ranked by Linnæus in the cardium genus, and are thoſe, ſtrictly ſpeaking, of which his genus is chiefly compoſed. Genus 3. *Truncati*, or flat-ſided cockles. Theſe laſt are ſuch cockles as are flattened, or have a truncated appearance on one ſide, as we ſee exemplified in cardium medium.

The cardium genus, as laid down by Linnæus, is far from exceptionable. It is adopted by the beſt continental writers, under the title of *Cardium bucarde, Cœurs, Conchæ cordiformes*, and other ſignificant appellations, alluding to the heart-ſhaped appearance which the ſhells exhibit, in a greater or leſs degree, when viewed ſideways. Theſe ſhells are of a ſomewhat cordiform ſhape, with the valves denticulated or folded at the margin; beaks contiguous; hinge with two oblique teeth in each valve near the beak, locking into each other; lateral teeth remote, and fitting alſo into each other.

MACTRA. Animal a tethys. Shell bivalve, unequilateral; valves equal; middle tooth of the hinge complicated, with a ſmall hollow on each ſide, and lateral remote teeth inſerted into each other.

Twenty-ſeven ſpecies of this genus are deſcribed by Linnæus and Gmelin. Lamarck propoſes to divide the Linnæan mactra into two genera, *mactra* and *lutraria*; both ſhells are unequilateral, and gaping at the ends, but the conſtruction and ſituation of the teeth are very different, as we ſee elucidated moſt completely by comparing the mactra ſtultorum of Linnæus with the mactra lutraria of the ſame author.

DONAX. Animal a tethys. Shell bivalve, with the margin in general crenulated, the anterior end very obtuſe; hinge with two teeth, a ſolitary one ſomewhat remote (the latter rarely double, triple, or none). Linn.

This genus, in the Linnæan ſyſtem, contains nineteen ſpecies. The donax of the modern continental naturaliſts is rather differently defined; they deſcribe it as a tranſverſe ſhell, with the ſides unequal, a little gaping at both ends, and having two muſcular impreſſions on the inſide of the ſhell; two teeth pointed towards the beaks in one valve, and a ſingle bifid tooth diſpoſed in a ſimilar manner in the other; and the ligament of the hinge on the outſide. This character agrees with the *Donax rugoſa* of Gmelin. Another genus is eſtabliſhed under the name of petricola, the character of which is exemplified in the Linnæan *Donax irus*, and *Venus lapicida* of Chemnitz. The ſhells of this new genus are unequilateral, a little gaping at both ſides, and having two muſcular impreſſions in the inſide of the ſhell: two teeth pointing towards the beaks in one valve, and a ſingle bifid tooth in the other; with the ligament of the hinge on the outſide.

VENUS. Animal a tethys. Shell bivalve, anterior margin with incumbent lips; hinge with three teeth, all which are approximate, the lateral ones divergent at the tip; "vulva et anus diſtincta." Linn.

Theſe are divided by Linnæus into two ſections; * pubentes, and ** impuberes, the laſt of which is ſubdivided into three families, † ſubcordatæ, †† orbiculatæ, and ††† ovales, ſupra rimam ſubangulatæ. The total number of ſpecies deſcribed in the "Gmelinian Syſtema," amounts to one hundred and forty-five. It is chiefly in the deſcriptions of the ſhells of this genus that Linnæus has adopted terms which we do not feel at liberty to render into common language for the peruſal of the general reader.

Many of the ſhells of this genus were arranged by writers previous to the time of Linnæus under the title of chama. The animal is deſcribed as a tethys differing from that of the cardium, chiefly, in having the foot of the animal when protruded lamina-formed, inſtead of hooked, and as a molluſcous animal, taking a variety of forms when the creature moves. It ſhould however be obſerved that we are yet very imperfectly acquainted with the animals inhabiting this extenſive tribe of ſhells.

SPONDYLUS. Animal a tethys. Shell with unequal valves, hard, and rigid; hinge with two recurved teeth, and a ſmall hollow between.

The Linnæan ſpondyli are few in number, the laſt edition of the "Syſtema Naturæ," comprehending no more than four ſpecies. The ſpondyli have been by ſome called thorny oyſters. Rumphius, Argenville, Seba, and Davila, rank them as oyſters; while Liſter, Woodward, Gualtieri, Linnæus, Meuſchen and Da Coſta conſider them as a diſtinct genus, under the name of ſpondylus. The ſpondyli are either earleſs or furniſhed with ears; the valves uneven, thick, and rude or uncouth, and forming in their general exterior an intermediate natural family between the oyſter an deſcallop. Lamarck, and other late French writers, divide the Linnæan ſpondyli into two genera, *ſpondylus* and *plicatula*. One eſſential diſtinction between theſe ſhells conſiſts in the ſpondylus having ears, and the plicatula being without; but this is not the only difference, a ſtriking character is drawn from the ſtructure and appearance of the beak of the lower valve, which projects beyond the beak of the upper one, and in ſpondylus exhibits a plain triangular flat ſpace, divided by a furrow: while in the genus plicatula the beak has no ſuch characteriſtic ſpace or flat ſurface, and the edges are rumpled or folded. Theſe new genera are well exemplified in the two Linnæan ſhells, ſpondylus gaedaropus, and ſpondylus plicatulus.

CHAMA. Animal a tethys. Shell bivalve, rather coarſe; hinge with a callous gibboſity, obliquely inſerted into an oblique hollow; anterior ſlope cloſed (valva clauſa abſque nymphis, Linn.)

In Da Coſta's "Scheme of Shells," the Linnæan chamæ are divided into two genera, tridacnæ or baſon conques, and chamæ or gapers. The tridacnæ are ſhells of equal valves, and diſſimilar ſides, in hinge and appearance like the heart cockles, but on the longeſt ſide from the beak to near the extreme margin the two valves are open, leaving a large oval or heart-ſhaped gap, the lips of which are very broad, and turn upon the edges. The chama gigas of Linnæus is of this family, and is the largeſt and heavieſt ſhell at preſent known, weighing from ſix to ſeven hundred pounds. The chamæ, or gapers, alſo called purrs, have a broad, thick, and large tooth at their hinge, and are abruptly cut off on one ſide, which ſide is always open or gaping.

The genus tridacna is retained by the lateſt French writers, with ſome amendment in the definition of the character. They deſcribe it as an equilateral and ſubtranſverſe ſhell, with two compreſſed teeth in the hinge, and the lunule at the poſterior ſlope gaping. The chamæ of theſe authors are adherent to other bodies, and have the valves unequal, and the inſide of each marked with two muſcular impreſſions; and the hinge conſiſting of a ſingle thick oblique tooth. Hippopus, cardita, and iſocardia, are alſo new genera formed of the Linnæan chamæ; the laſt is an excellent genus, founded on the peculiar ſtructure of the chama cor of Linnæus: this ſhell is heart-ſhaped, with the valve unequal at the ſides; the beaks diverging ſomewhat ſpirally and remote; in one valve under the beak a flat tooth, locking horizontally between two in the valve oppoſite, and a ſingle diſtant tooth in the anterior part, below the ligament.

ARCA. Animal a tethys. Shell bivalve, equivalve; hinge with numerous ſharp teeth alternately inſerted between each other.

This genus is divided into two principal families, thoſe having the margin entire, and thoſe with the margin crenated; and both families are again ſubdivided into two ſections, the firſt diſtinguiſhed by having the beaks recurved, the other inflected; the ſpecies deſcribed altogether amount to forty-two.

This genus derives its name of arca, ark, or Noah's ark-ſhell, from the ſimilitude which moſt of the ſpecies bear when the valves are cloſed to a boat, or hull of a ſhip, "concha rhomboidalis naviculam exprimens." Liſter places ſome of theſe ſhells among the multarticulate cockles, and the reſt with the muſcles, under the title of many-toothed muſcles. Woodward ranks them among his "polyginglymi formâ oblongâ;" Argenville as a family of heart-cockles, and Davila and Gualtieri as a diſtinct genus: the firſt under the title of arca, the latter as "concha rhomboidalis." Theſe writers were ſucceeded by Linnæus, who conſidered theſe ſhells as a diſtinct genus, and called them arca.

The principal alteration in the Linnæan claſſification of the genus arca propoſed by late writers, is to retain only ſuch ſhells under the title of arca as are unequilateral, with the beaks remote; and have the line of the hinge ſimple and ſtraight throughout, with numerous teeth placed parallel to each other, and fitting or locking between thoſe on the oppoſite valve. Admitting this as the character of the arcæ, and it exactly correſponds with the arcæ noæ, and moſt others, the little ſilvery ark; arca nucleus of Linnæus, with its analogous ſpecies, is excluded. To comprehend the latter, a new genus is recently eſtabliſhed by the French writers under the name of nucule, or nucula, the character of which is remarkably deciſive: it is deſcribed as a triangular or oblong ſhell, with the ſides unequal; the hinge conſiſting of an angulated, or broken line beſet with numerous teeth, which are tranſverſe and parallel, and a ſingle oblique tooth placed under the beak, and out of the range of parallel teeth before mentioned. The beaks alſo, inſtead of being remote, as in arca noæ, are placed cloſe together, and turn backwards.

OSTREA. Animal a tethys. Shell bivalve, generally with unequal valves, and ſlightly eared; hinge without teeth, furniſhed with an ovate hollow, and moſtly lateral, tranſverſe furrows. "Vulva anuſque nullus," Linn.

Theſe are divided into three families, * valves radiated and eared, as in the ſcallops, * * rugged, or rough, as in the oyſter, * * * hinge with a perpendicular furrowed line, as in the ſpecies perna and iſognomum. The ſcallops are again ſubdivided into three ſections, namely, thoſe with the valves equilateral, and the ears equal; thoſe with the ears unequal, and having one of them generally ciliated with ſpines within; and thoſe with the valves gibbous on one ſide. The two other families are not ſubdivided.

The difference between the oyſter and the pecten tribe is ſo obviouſly impreſſed by the hand of nature on the reſpective ſhells which compoſe them, that few writers on this ſubject have paſſed ſilently over the impropriety of placing them together. If, however, we examine a number of the other ſhells included by Linnæus in the extenſive genus oſtrea, many will be found, which though leſs diſſimilar at the firſt view, equally deſerving of being conſidered generically diſtinct, as well as the two tribes before-mentioned. The form of the ſhell is ſufficient to guide us in an arrangement profeſſedly of ſhells; but when the peculiar ſtructure of the animal confirms the propriety of conſtituting new genera, no doubt can remain that ſuch amendment was requiſite. With reſpect to the oſtrea, the animals of ſeveral of its natural families are unknown; ſome of the oyſter and pecten tribe are, on the contrary, well aſcertained, and theſe are proved to be very diſtinct.

As Linnæus conſiders theſe animals the ſame, and deſcribes them as a tethys, it may not be improper to ſpeak more fully on this ſubject. The ſcallop differs from the oyſter in being endowed with a higher locomotive power: the animal is different in having the branchiæ cirrhated, or fringed; in being furniſhed with a kind of foot, which it protrudes from the ſhell near the auricle of the hinge; and in throwing out a byſſus like the pinna and the muſcle, by which it affixes itſelf to other bodies. Ariſtotle, and other ancient writers, attribute to the ſcallop the power of ſpringing from place to place, a fact pretty correctly aſcertained by the obſervations of the moderns. Argenville deſcribes the proceſs of its movements both in the water and out; he relates, that when left dry, by a ſudden and violent cloſing of its valves, aſſiſted by the foot, it has the power of ſpringing four or five inches at a jerk, repeating this motion in order to regain its element. In the water, it is aſſerted by this writer, the ſcallop has the power of riſing and ſuſtaining itſelf near the ſurface, turning about in various directions, and on any alarm ſuddenly cloſing the valves and ſinking to the bottom. The oyſter has the branchiæ ſimple, and not fringed, and is unfurniſhed either with a foot, or with byſſus; and its powers of motion conſiſt in turning either the flat or convex ſide upwards or downwards, and even to effect this, the animal takes advantage of the force of the ebbing or flowing of the water to aſſiſt it. Vide Dr. Pultney's Cat.—Liſter on Scallop, in Phil. Tranſ. &c.

Before the time of Linnæus, moſt writers conſidered the ſcallops and oyſters as diſtinct. Gualtieri deſcribes the ſcallops as a particular family, and divides them into two genera, or thoſe with equal, and thoſe with unequal valves; the firſt of which he calls *pecten*, the latter *concha pectinata*; and the ſcallops with unequal or ſingle ears, he calls *pectunculi*. The oſtrea is ranked as a diſtinct family by moſt authors. Da Coſta obſerves that the "head or eſſential character of the eſcallop family is a trigonal ſinus, and an elaſtic cartilage for its hinge in the very centre of the top of the ſhell." "The oyſters have unequal valves, though there are ſome ſpecies that have equal valves, but none are eared. The hinge of this family has not any teeth, but conſiſts of one large inarticulate gutter, running the length of the top of the ſhell, in both ſhells alike, and is covered and filled with a ſtrong cartilage." We ſhould add, that in the ſcheme of ſhells propoſed by this writer, the ſpondylus forms an intermediate genus between the pecten and oyſter.

In Lamarck's arrangement, the two genera, *huitre*, oſtrea, and *peigne*, pecten, are retained; but four other genera are conſtituted, under the names of *malleus*, *perna*, *lima*, and *pedum*, into which the Linnæan oſtreæ are diſtributed. Latreille forms another genus under the name of *gryphus*, the oſtrea gryphus of Linnæus, a ſhell found only in a foſſil ſtate. We are not excluſively indebted, however, to Latreille for the eſtabliſhment of this genus. Vide "Donov. Tour South Wales and Monmouthſhire;" in which the courſe of an immenſe ſtratum of theſe antediluvian ſhells is particularly deſcribed, with remarks on the genus oſtrea and gryphus.

ANOMIA. Animal, a ciliated ſtrap-ſhaped body, with briſtles or fringe affixed to the upper valve; arms two, linear, longer than the body, connivent, projecting, alternate on the valve, and ciliated each ſide, the fringe affixed to each valve. Shell inequivalve, one of the valves flattiſh; the other gibbous at the baſe with the beak produced, and generally curved over the hinge; one of the valves often perforated near the baſe; hinge with a linear prominent cicatrix, and a lateral tooth placed within, but in the flat valve on the very margin. Two bony rays for the baſe of the animal.

Many of the Linnæan ſpecies of anomia are found in a foſſil ſtate only, and rarely afford an opportunity of inſpecting their internal ſtructure; neither is it reaſonable to imagine we ſhall ever become acquainted with the animals by which they were inhabited. Our obſervations on theſe points muſt be confined to the recent kinds only, which, ſo far as they have been attentively examined, are found to comprehend ſhells extremely diſſimilar in ſtructure, and to be inhabited by animals differing in many eſſential particulars. It is remarked by Dr. Pultney, that the animal of the anomia is different from that of any other ſhell-fiſh, and is not reducible to any of thoſe in a molluſcous ſtate hitherto known. Hence, probably, the name Linnæus impoſed upon it, *Ανόμια*. "quaſi irregularis diſſimilis à lege diſcrepans." The animal of the anomia cepa is figured by Murray, in his "Fundamenta Teſtaceologiæ," t. 2. f. 23; and that of another ſpecies, by Forſkäl, in his "Icones Animalium," t. 6. 40. B. under the name of anomia tridentata. The diſſimilarity of theſe two renders it highly probable, that in the different ſhells which come under the appellation of this genus, the inhabitant animal is various. Linnæus deſcribes that of the anomia patelliformis as extending from its body a tongue-like proceſs fringed with fine hairs, and furniſhed with two extenſive ciliated arms, by which it is enabled to open and ſhut the ſhell. In the anomia tridentata, the animal is furniſhed with two flat, wedge-ſhaped, trilobated arms, placed oppoſite to each other; theſe it protrudes out of the ſhell when it moves, and they are the organs by means of which it ſwims in the ſea. Some other kinds of anomiæ are inhabited by animals which, it is ſuppoſed from the ſtructure of the ſhell, cannot open the valves to ſtretch forth arms, but are furniſhed with proceſſes of a different nature, which they protrude through the aperture or perforations at the beak; and other kinds again, inſtead of arms, have only a ligament paſſing through the perforations of the ſhell, by means of which it is firmly fixed to other bodies.

Columna is the firſt writer who ſpeaks of ſhells of this kind; he deſcribes ſome few of the foſſil tribe (the only ſpecies known in his time) under the title of "Conchæ rariores anomiæ." Hence the term anomia was afterwards employed by other writers, and has ſince become the univerſal name for this family of ſhells. Liſter figures ſeveral ſpecies of the foſſil kinds in his "Appendix de Conchitis" to his "Hiſtoria Conchyliorum". Woodward forms an arrangement of them under the name of anomia, ranking them with the ſhells of unequal valves, not eared, both valves convex, and one of them beaked, and theſe he divides into three families, the ſmooth, ſtriated, and ſulcated. Gualtieri figures ſome few of the recent kinds as a new genus under the title of terebratula. Argenville places ſome of the anomiæ among his heart cockles. Davila treats them as a genus of his oyſters; Da Coſta as a genus of bivalves with unequal earleſs valves, the beak of the largeſt or under valve greatly produced, and riſing or curving over the beak of the ſmaller or upper valve, which is pierced through like a tube: the hinge is in articulation toothleſs, and they have always a remarkable interior ſtructure. Theſe are the terebratulæ of ſome late writers, and comprehend only part of the Linnæan anomiæ.

Thoſe ſhells of the recent kinds among the anomiæ of Linnæus, which are moſt diſſimilar in ſtructure, are the ſpecies terebratula, placenta, and ephippium; each of which ſtands at the head of a natural family, and offers characters which may be adopted with facility as diſtinctions of ſo many genera. We are perſuaded the genera formed by the ſubdiviſion of the Linnæan anomiæ might be extended with much propriety to a greater number ſtill, but we are unwilling to increaſe them without the moſt abſolute neceſſity. With reſpect to the foſſil kinds of Linnæan anomiæ, ſome may be referred to the genera above mentioned, others are in no manner applicable to them, and for the arrangement of ſuch it is requiſite to form new genera. Lamarck propoſes one, calceola, derived from the characters of the anomia ſandalium of Linnæus, and his genus crania formed of the Linnæan anomia craniolaris may be conſidered as in a great meaſure appertaining to the foſſil ſhells only. Theſe genera are laid down with perſpicuity, but Lamarck we are perſuaded might have proceeded further. We conſider Linnæus oftentimes blameable for intermixing the recent and foſſil ſhells promiſcuouſly together, and may be therefore ourſelves excuſed ſometimes at leaſt for abſtaining from his example. Lamarck thinks differently; he approves this method, and having ventured from the boundaries of the preſent into the labyrinths of the antediluvian creation, much was expected; a greater number of new genera might have been eſtabliſhed, thoſe at preſent formed being altogether inadequate to the reception of thoſe numerous remains of the teſtacea which are admitted among the anomiæ by the Linnæan conchologiſt.

But to return to the recent anomiæ:—What, we would inquire, could poſſibly induce Linnæus to place that ſingular bivalve, called from its tranſparency by the Engliſh collector "the Chineſe glaſs window" among the anomiæ?—Or what again can be more remote than the eſſential character of his anomia ephippium and terebratula?—In the firſt, which is to be found in his Syſtema under the name of anomia placenta, both valves are of an equal ſize and form; in ephippium the valves are unequal, one being flat, and the other convex, as in the oyſter; in ephippium the flat valve is perforated with a round hole in the diſk near the hinge through which a ligament paſſes, and by this means affixed it to ſtones and other bodies; the A. placenta has no ſuch perforation. In A. terebratula there is a perforation; but inſtead of being ſituated in the flatter valve it appears at the tip of the long beak into which the head of the convex valve is elongated. Near the hinge in one valve of A. placenta are two longitudinal lamelliform proceſſes, which approach near the beaks, and thence diverge obliquely ſo as to reſemble the letter V, and upon the valve oppoſite two correſponding proceſſes longitudinally cleft, in which, when the ſhell is cloſed, two lamelliform teeth repoſe. An internal ſtructure of longitudinal proceſſes occurs in the ſpecies terebratula, but very different from the preceding, and no ſuch internal ſtructure occurs in the anomia ephippium. Theſe characters denote ſufficiently that they are not only eſſentially different in the conformation of their ſhell, but that they are inhabited by animals diſtinct from each other.

Mytilus. Animal an aſcidia? Shell bivalve, rough, uſually affixed by a beard or byſſus of ſilky filaments: hinge in general without teeth, and except in a few ſpecies with a ſubulate excavated, longitudinal line. Linn.

The Linnæan mytili are by no means inconſiderable in number, and as they comprehend many ſhells very diſtinct in appearance, and ſome eſſential particulars, are neceſſarily diſtributed into ſeveral ſections, or families, ſuch as * paraſitici, thoſe affixed by claws, exemplified in mytilus criſta galli; ** plani, &c, flat, or compreſſed into a flattened form, and ſlightly eared, as in mytilus margaritiferus; or *** ventricoſculi, ventricoſe, as in mytilus edulis. The older writers appear to be perfectly agreed as to the mytilus genus, but the moderns think it neceſſary to divide them into two or more genera. Lamarck ſeparates them into mytilus (moule), modiolus (modiole), and anodonta (anodonte). In defining the mytili he notices in particular the unguiculated, or claw-like termination of the ſhell at the narroweſt end as a peculiar character. We do not perceive the abſolute utility of his ſecond genus, modiole, though we think it admiſſible, but we perfectly agree in the adoption of the latter anodonta. This laſt mentioned genus conſiſts of what are vulgarly called the river, or freſh water muſcles, ſhells which we have always conceived it improper to refer to the ſame genus as the marine mytili. In the colour of the valves, and form and ſituation of the beaks, the moſt obvious diſſimilitude prevails, and a diſtinction ſtill more evident reſulting from the different conformation of the animal occurs in the inſide of the ſhell, which exhibits three impreſſions of muſcles or ligaments by means of which the animal is attached to the ſhells, while the ſhells of the common muſcle, and its congeneres, have only one ſuch impreſſion.

Pinna. Animal limax. Shell ſub-bivalve, fragile, erect, gaping, and furniſhed with a byſſus, or beard; hinge without teeth, the valves uniting into one. Linn.

This genus is well defined; the ſhells of which it conſiſts are wedge-ſhaped, or of a ſomewhat triangular form, widening from a pointed or narrow top to a very broad end. The hinge is inarticulate, the two valves being united in that by part, and thus forming, what Linnæus truly terms it, a ſub-bivalve, for it is not ſtrictly of two valves, being thus connected. The pinnæ are known by different writers under the various appellations of ſea-hams, ſea-wings, and pinnæ marinæ, or by others ſilk-worms of the ſea, which laſt they obtain from the quantity of fine ſtrong brown byſſus, which the animals produce, and by means of which they affix themſelves to the rocks; the byſſus conſiſts of fine ſilky fibres of a brown colour, and which is eaſily woven into ſtuff or ſmall articles of dreſs. Among the ancient Romans this kind of ſilk was held in conſiderable eſteem: it is even ſaid that there are ſtill manufactories of it at Naples, Meſſina, and Palermo.

Eighteen ſpecies of this genus are deſcribed in the laſt edition of the Syſtema Naturæ.

Argonauta. Animal ſepia, or clio. Shell univalve, ſpiral, involute, membranaceous, and unilocular, or conſiſting of a ſingle cell. Linn.

The principal ſpecies in this genus of ſhells is the Linnæan argonauta argo, the celebrated nautilus of Pliny, lib. ix. 29, the animal ſuppoſed to have taught men the uſe of ſails, and art of navigation in the early ages of ſociety. The ancients knew this ſpecies by the name of nautilus, as appears ſufficiently obvious from many paſſages to be found in their writings. Linnæus, however, in conformity with Rumphius, applies the name of nautilus to a chambered ſhell of a very different kind, (ſee Nautilus), and retains the nautili of the ancients, under the title of argonauta, with the eſſential character above-mentioned.

In the Gmelinian edition of the Syſtema Naturæ, the number of ſpecies deſcribed under the genus argonauta amount to five, argo, vitreus, cymbium, cornu, and arctica. But the minute obſerver of nature diſpoſed to deſcend to the inveſtigation of the microſcopic kinds of ſhells will be able to add conſiderably to this number; a work publiſhed in Germany in 1798, the united labours of our friend L. A. Fichtell, and C. A. Moll, and entitled "Teſtacea Microſpica aliaque minuta ex generibus Argonauta et Nautilus ad naturam picta et deſcripta," contains in particular, a number of new ſpecies in this curious genus, and a few others are known to us which we have reaſon to apprehend have not been noticed by any other writers. By the acceſſion of theſe latter ſpecies the genus becomes materially enlarged; but we have, at the ſame time, to obſerve that the whole of the Gmelinian ſhells, deſcribed under this generic title, are not ſtrictly admiſſible among the argonautæ, and that the removal of theſe will occaſion a ſlight reduction of the ſpecies already mentioned.

That very rare ſhell known among collectors by the name of glaſſy nautilus, the argonauta vitreus of Gmelin, is ſeparated by Lamarck from argonautæ, and conſtituted a new genus under the name of carinaria. In the Linnæan ſyſtem it would be difficult to refer it with certainty to any genus. Linnæus was himſelf in doubt where to place it, and at length referred it to the limpet tribe, under the name of patella criſtata, but it cannot ſurely belong to this genus. In the laſt edition of the Syſtema Naturæ, we ſee it tranſpoſed from thence to the argonautæ with more propriety, but we are ſtill perſuaded it cannot claim a place in this genus, though it is more cloſely allied to it than any other of the Linnæan genera; it is certainly of a new genus as Lamarck deſcribes it. The principal diſtinction between thoſe two genera, the argonauta and carinaria, is very ſtriking; in the true argonauta, (or nautilus of the ancients) the ſpiral involution turns into the opening of the ſhell, whereas in carinaria, the ſpire is ſituated at the ſummit of the ſhell and the mouth is entire. This character we think alone ſufficiently deciſive in defining the eſſential characters of the two genera. The carinaria is further diſtinguiſhed by the ſhell being conic, and flattened at the ſides, the ſpiral whorl very ſmall, the back furniſhed with a ſingle denticulated keel, and the mouth, or aperture of the ſhell, of an oval-oblong form, narrower neareſt the angle of the keel. The argonauta ſhell, inſtead of being conic, is ſomewhat boat-ſhaped, and has from this very circumſtance been named cymbium, both by Gualtieri and Teſſin; and the dorſal carination which is ſingle and denticulated in carinaria, is uniformly double and tuberculated in argonauta.

In concluſion of our remarks on this genus, it will be proper to obſerve that the glaſſy nautilus, or carinaria vitrea, is one of the moſt choice and uncommon of the teſtaceous tribe;

it is not, however, unique, for we know of three ſpecimens, one of which is in the cabinet of Mr. Jennings in England, and the two others in the Muſeum of Natural Hiſtory in Paris, one of which was obtained from Lyonet's cabinet. A large foſſil ſhell of the argonauta genus, a ſingular ſpecies, and the only one we are acquainted with, occurs in the London Muſeum.

NAUTILUS. Shell univalve, divided into ſeveral departments, communicating with each other by an aperture or ſiphunculus.

The Linnæan nautili conſiſt of two principal families, thoſe which are ſpiral and rounded, and ſuch as are elongated and ſtraight. Of the ſpiral kinds there are two diſtinct ſections, the firſt of which have the whorls contiguous, the other the whorls ſeparated; the nautili of a ſtraight form are comprehended in one ſection only.

Under the general title of nautilus, Linnæus includes the three genera of modern naturaliſts, nautilus, ſpirula, and orthocera, with ſome others which may hereafter, on accurate inveſtigation, be found generically diſtinct likewiſe. The nautilus is a ſpiral rounded ſhell, having the laſt whorl very large, and enveloping the others, which are numerous, and divided internally into many chambers by tranſverſe partitions, the diſk of which is perforated by a ſiphunculus or tube. This character is drawn from the nautilus pompilius of Linnæus, a ſhell admitted by the lateſt authorities as an amplification of the nautilus genus; of the modern ſchool only we would obſerve, for it has been previouſly ſhewn, under the genus argonauta, that it is not the nautilus of the ancients. The character of the new genus ſpirula, is derived from the nautilus ſpirula of Linnæus, (erroneouſly rendered ſpicula in Gmel. Syſt.) or what we call the ram's horn. This ſhell is truly of the lituus or crozier family, being of a ſpiral ſtructure with the whorls ſeparated, and the laſt chamber at the aperture elongated into a ſtraight cylindrical ſtem. Linnæus deſcribes only the ſpiral termination of the ſhell, which being of a concamerated or chambered ſtructure, and perforated with a ſiphunculus; induced that naturaliſt to place it with the nautili, notwithſtanding the ſtriking diſſimilarity of the diſpoſition of the ſpiral involutions. This ſhell, when perfect, affords an eſſential character which at once removes it from the genus nautilus, in which Linnæus places it; namely the laſt or cylindrical chamber, which is alone ſufficient to diſtinguiſh it. We may eaſily preſume that no blame attaches to Linnæus in this particular reſpect, for it is pretty certain that naturaliſt never ſaw the perfect ſhell. In collections we have at various times ſeen ſome thouſands of the ſpiral terminations, (for it is a very common Weſt Indian ſhell,) ſcarcely one of which has retained the ſlighteſt veſtige of this chamber, though all appear rudely broken, and different from a natural termination or aperture. This chamber of the ſhell is extremely thin and brittle, inſomuch that the ſlighteſt agitation of the waves will deſtroy it, and as thoſe ſhells inhabit the deep waters, and are collected by the curious only from the *rejectamenta* of the ſea caſt upon the beach in ſtorms, it is natural to conclude that it is rarely ſeen complete. It was not till of late years that the true form of the perfect ſhell appears to have been aſcertained. The orthocera is the orthoceros of Gualtieri and Breynius revived. This ſhell is ſtraight or arched, and a little conic, with diſtinct chambers formed by tranſverſe ſimple diviſions perforated by a tube, which is ſometimes placed centrally and ſometimes laterally. We are of opinion this amendment would be improved by forming two genera of the orthocera, one containing the ſtraight and the other the arcuated kinds; and indeed we conceive ſtill further that thoſe, with the ſiphunculus placed on one ſide, ſhould form a diſtinct genus from thoſe having the ſiphunculus in the centre. The Linnæan character of the nautilus confounds all theſe diſtinctions; they are all nautili of that writer.

Among the teſtaceological remains of the antediluvian world, are many ſingular ſpiral ſhells, allied to, or of the ſame genera with the foregoing, and others which, though ſpiral and concamerated, cannot poſſibly be reduced to theſe tribes; ſuch as the ammonites, the orbulites of Lamarck, hélicite of Guettard, baculites of Faujas, and the belemnites, or "thunder-bolts," of moſt authors. See article FOSSILS.

CONUS. Animal a limax. Shell univalve, convoluted, and turbinated; aperture or opening effuſe, longitudinal, linear, toothleſs, with the baſe entire; pillar ſmooth.

This genus is divided into five diſtinct families. * Truncati, having the ſpire nearly truncated. ** Pyriformes, with the baſe rotundate and ſub-cylindrical; the cylinder half as long again as the ſpire. *** Elongati, with the baſe rotundate, cylinder twice the length of the ſpire. **** Ventricoſe in the middle, and narrow at each end. ***** Ventricoſe; emits a tinkling ſound, when thrown on its back upon a board or table. The total number of ſpecies included in this genus, in the laſt edition of the Syſtema Naturæ, amounts to ſeventy-one. Many of the conus, or cone tribe, are beautiful ſhells, and bear a high price on account of their rarity; the cedo nulli of Lyonet, valued at one hundred guineas, is of this genus. We have no ſpecies of this genus upon the Engliſh coaſts. Some very curious kinds have been diſcovered in a foſſil ſtate in England, chiefly in the chalk cliffs of Hampſhire.

CYPRÆA. Animal a limax. Shell univalve, involuted, ſubovate, obtuſe, and ſmooth; aperture effuſe at each end, linear, dentated at both ſides and longitudinal.

Linnæus forms ſeveral diſtinct families of the cypræa genus, one of which is diſtinguiſhed by being obtuſe, and without any manifeſt ſpire; ſuch, for example, as the ſpecies caput ſerpentinus and tigris, the laſt of which is well known by the name of tiger cowry; another kind is perforated, or furniſhed with an umbilicus, as in cypræa ziczac; and a third ſort is margined like the common Weſt India cowry, vulgarly called "blackmoor's teeth," cypræa moneta of Linnæus. In the young ſtate, the cyprææ have much the appearance of a volute, and are entirely deſtitute of the thick denticulated lip or margin, ſo obvious in the adult ſhells. Writers have been even ſo far miſled by this ſpecious appearance, as to deſcribe the young of ſeveral kinds for ſhells of the volute genus. The voluta jonenſis of Pennant's Britiſh Zoology, is clearly nothing more than the young of the common Engliſh cowry, cypræa pediculus, which that writer miſtakes for a perfect ſhell.

BULLA. Animal a limax. Shell univalve, convoluted, and unarmed with teeth; aperture ſomewhat ſtraightened, oblong, longitudinal, and very entire at the baſe; pillar lip oblique and ſmooth.

The arrangement of the bulla family is very confuſed in the works of the old writers. Liſter makes them a genus of the cowry, and calls it concha veneris baſi umbilicatâ. Grew and Bonanni place it with the ſnails; Argenville and Davila with the cochleæ globoſæ; and Gualtieri as a genus between the paper nautili (argonauta) and the cowries. The term bulla implying the bubble-like form, or ſwollen appearance of the ſhell, was applied by Rumphius to the bulla ampulla, from whom it was adopted by Klein, and afterwards by Linnæus as a generic appellation. The ſhells included by this laſt-mentioned writer under the name of bulla, are more than commonly anomalous in habit and form; few inſtances can be adduced of greater diſſimilarity than is obſervable between the bulla ovum, ficus, terebellum, and virginea. The ſpecies ovum has the habit of a cowry, the ficus that of a murex, the terebellum that of a cone, or a buccinum, and the virginea of a turbinated helix. The bulla achatina and the bulla cylindrica likewiſe offer characteriſtic differences, which may, without any impropriety, conſtitute generical diſtinctions.

According to Linnæus, the animal of the bulla is a limax; but if it be ſuch, as Dr. Pultney obſerves, in any particular ſpecies examined by that author, it does not hold throughout the whole genus; nor even in thoſe which were primarily and eminently diſtinguiſhed by the name of bulla. In ſome ſpecies the animal appears more to reſemble an aſcidia. The animal of bulla aperta forms a new genus in Lamarck's arrangement, under the title of bullæa. The animal of bulla lignaria is furniſhed with maſticatory organs, conſiſting of three teſtaceous bodies placed within the ſtomach or gizzard, by the help of which it is enabled to break ſmall ſhells and hard ſubſtances. This inſtrument was firſt diſcovered by Plancus in the bulla aperta, in which we have ourſelves obſerved it. An account of that in the gizzard of the bulla lignaria, by Mr. G. Humphreys, is inſerted in the Linnæan Tranſactions. Theſe latter mentioned teſtaceous bodies were firſt introduced among conchologiſts as a new genus of ſhells by M. Gioëni, a Sicilian naturaliſt, after whom it was named gioenia, by Bruguière. Retzius alſo deſcribes it, but under the name of tricla. An account of the diſcovery of this important error, was publiſhed by Draparnaud, in the Bulletin des Sciences, n. 39,

Voluta. Animal a limax. Shell ſingle-celled and ſpiral; aperture without a beak, ſomewhat effuſe; pillar folded or plaited, and generally without lips or perforations.

This extenſive genus is diſperſed by Linnæus into the following principal families. * Aperture or opening entire. ** Somewhat cylindrical and emarginate. *** Obovate, effuſe, and emarginate. **** Fuſiform. ***** Ventricoſe; ſpire papillary at the tip. The whole includes one hundred and forty-two ſpecies.

Linnæus has deſervedly incurred ſome blame for having too often tranſpoſed long eſtabliſhed names from objects to which they were before aſſigned, and impoſed them on others without any apparent or ſufficient reaſon, which were never underſtood among his predeceſſors by thoſe terms. An inſtance of this kind of innovation occurs to us at preſent. The term voluta, derived "a volvendo forte revolutione ſpirali," was always applied to the cone tribe, and is very expreſſive of the peculiar roiled, or involuted ſtructure of thoſe ſhells; Linnæus deprived them of that name, called them conus, and gave the title of voluta to the ſhells of which we are about to treat. The voluta genus, furthermore, as now laid down, is highly objectionable. Linnæus, in the eſtabliſhment of this new genus, has been leſs attentive to the natural families of ſhells than could have been wiſhed, and has, by that means, brought promiſcuouſly together ſhells which ſcarcely agree in any one individual reſpect, except in having plaits or folds upon the pillar.

This error does not reſt, however, entirely with Linnæus, for he was not the original projector of the genus; he only adopted it, and gave it the name it now bears, when he might with more propriety have expunged it, or diſperſed the ſhells contained into other genera. In Liſter's work, ſection 11. lib. 4, we find a claſs of ſhells entitled, "buccina columella dentata," in which that author arranges the buccina and other ſhells which have the pillar plaited. Linnæus, by the adoption of this genus, under the title of voluta, comprehends a number of ſhells poſſeſſing very diſtinct generic characters, and which had been diſtinguiſhed by his predeceſſors under the various names of oliva, rhombus, cylindricus, turricula, mitra, muſica, and others applicable either to their figure, or to the eſſential characteriſtics of their reſpective natural families. It is a ſingular corroboration of the accuracy of the ideas entertained by thoſe writers, that the animals inhabiting the ſhells above-mentioned, have been recently aſcertained to be as diſſimilar in ſtructure as the ſhells. Linnæus conſidered the animal of all the volutes as a limax or ſlug; but from the inveſtigation of Adanſon and Argenville, and ſince the time of Müller, Poli, Lamarck, and many others, it appears that no opinion was ever more unfounded; the animal of each family being differently formed, and adapted to the peculiar ſhape or ſtructure of the ſhell.

Da Coſta, in his "Elements of Conchology," aboliſhes the Linnæan voluta genus altogether, but the ſhells are not reſtored according to his method to their proper or natural families; his definitions want preciſion, and his ſcheme is confuſed and uncouth. But notwithſtanding, the ſcheme of claſſification laid down by Da Coſta was never acceded to by conchologiſts, and certainly never will now; from the circumſtance of its being the only elementary work in the Engliſh language (Barbut's Gen. Verm. excepted) it has anſwered one uſeful purpoſe, that of directing the general collector to diſpoſe their ſhells into particular families, in a more comprehenſive manner than could have been accompliſhed by attending to the Linnæan arrangement. Thus, in the Linnæan volutæ, the families are diſtinguiſhed by the title of papal crowns, Perſian crowns, melons, olives, midas's ears, mitres, muſics, and other trivial appellations, by which they are known even to this day among Engliſh collectors. As Da Coſta derived his principal diſtinctions of theſe families from writers who flouriſhed before Linnæus, ſo alſo it has happened with the French conchologiſts: they diſapprove of the Linnæan arrangement, but retain moſt of the original families deſcribed by thoſe earlier writers, and thus we ſee at the preſent time the genera olive, turbinelle, mitre, harpe, &c. recaſt and adopted with ſome improvements, by the beſt informed conchologiſts of that country.

Buccinum. Animal a limax. Shell univalve, ſpiral, gibbous; aperture ovate, terminating in a ſhort canal, leaning to the right, with a retuſe beak, or tip; inner lip expanded.

The buccina are ſeparated into ſections, in the following order: * ampullacea, &c. inflated, rounded, thin, and ſubdiaphanous, and brittle. ** Caſſidea, caudata, &c.; tail ſhort, exſerted, and reflected; lip unarmed outwardly. *** Caſſidea, unguiculata, &c. lip aculeated on the outſide of the poſterior part, otherwiſe reſembling the laſt diviſion. **** Calloſa, &c. pillar lip dilated and thickened. ***** Detrita, &c. pillar lip appearing as if worn flat. ****** Laevigata, &c. ſmooth, not enumerated in the former diviſions.

Linnæus has occaſioned ſtrange confuſion in his claſſification of the ſhells which he denominated buccinum: in the indefinite latitude which his character of this genus admits, he embraces ſhells very little, if at all, allied to each other, in any other reſpect than according with his character. Thus the cochleæ globoſæ of Rumpſius and Argenville, the cochleæ pyriformes of Gualtieri, and other diſtinct natural families of writers, prior, as well as ſubſequent, are confounded altogether in this moſt copious genus. It is not ſufficient that theſe be kept apart by being referred to different families, they ſhould certainly conſtitute diſtinct genera.

nera. The French have long diſtinguiſhed theſe different ſhells, by the appellations on tonne, caſque, harpe, pourpre, &c.; the Engliſh collector will better conceive, perhaps, what is meant by the trivial diſtinctions of tuns, partridges, harps, and whelks. In Lamarck's arrangement, they aſſume a more claſſic form, and are defined generically, under the title of dolium, harpa, caſſis, terebra, purpura, buccinum, and naſſa, as will be more accurately explained hereafter.

Strombus. Animal a limax. Shell univalve and ſpiral; lip of the aperture often much dilated, and produced into a groove leaning to the left.

Previous to the time of Linnæus, the term ſtrombi was applied to ſhells of a different deſcription from thoſe at preſent underſtood by that name. Under the title of ſtrombi, the Greeks originally deſignated all kinds of turbinated ſhells. Among the older writers, the term ſtrombi was indiſcriminately employed as ſynonymous with turbo, trochus, and ſometimes with murex. Strombi was then a term indefinite, but rather applicable to the ſlender kinds, murices, or rhombi.

Linnæus was the firſt who limited the application of the word ſtrombus to thoſe univalve ſhells, which have the canule or gutter directed to the left, and the lip expanded. He was not, however, the firſt to eſtabliſh the genus. Liſter deſcribes the ſhells of this family which have the lip entire, under the title of purpuræ ſeu buccina bilinguia, and claſſes them in the twelfth ſection of his fourth book. Rumpfius, and after him Meuſchen, make a diſtinct genus of them, under the title of alatæ, and by this name alatus, they are pretty generally known to this day, it being well known that Solander intended to have eſtabliſhed ſuch a genus under this name. Davila ranks theſe winged alatæ among his murices, but independently, and as a diſtinct genus, conſiſting of ſimple or entire winged ſhells; placing immediately after them another genus, comprehending thoſe which have the expanded lip digitated, or elongated into pronglike proceſſes. Linnæus rejects this arrangement of Davila, including in his genus ſtrombus, the whole of thoſe winged or alated ſhells; not in a promiſcuous manner, but in ſections or families, as * Digitati, labio in lacinias lineares exeunte. ** Lobati. *** Ampliati. The French writers to this time, on the contrary, follow the example of Davila, and form two diſtinct genera of theſe ſhells under the title of ſtrombus, and pterocera, and to theſe another has been lately added after our countryman Liſter, under the name of roſtellaria.

On this arrangement, the genus ſtrombus is deſcribed as being a ventricoſe ſhell, terminated at the baſe by a ſhort canal, ſloping off or truncated: the right margin or lip dilating or expanding with age into a ſimple or entire wing-like lobe, and having a ſinus beneath, diſtinct from the ſlope of the baſe, or in the Linnæan language, the beak. This genus is ſufficiently explained by the ſhell called among Engliſh collectors the "pugiliſt's fiſt," ſtrombus pugilis of Linnæus. The genus pterocera, has the ſhell ventricoſe, terminated below by a long canal; the right margin, or lip expanding with age into a digitated wing, and having a ſinus near the baſe. The Linnæan ſtrombus lambis is of this genus. The generic character of roſtellaria is drawn from the ſtrombus fuſus of Linnæus, deſcribed by Liſter, t. 854. f. 11.; and Martini, t. 159, f. 1500. The ſhell is fuſiform, terminated beneath in a canal, ending in a ſubulated or pointed beak; right margin entire or dentated more or leſs dilated into a wing-like proceſs with age, and having a ſinus contiguous to the canal or gutter.

We may laſtly add, that the young ſhells of the ſtrombus genus do not poſſeſs the ſtriking peculiarity of the ample dilated lip before-mentioned, and that in conſequence, ſuch ſhells have been ſometimes referred to very different genera, an error committed by ſome of the beſt among the early writers.

Murex. Animal a limax. Shell inequivalve, ſpiral, rough, with membranaceous ſutures; aperture ending in an entire canal; either ſtraight, or ſomewhat aſcending.

The Linnæan genus murex is very extenſive; in the laſt edition of the Syſtema Naturæ a hundred and ſixty three ſpecies are deſcribed under the following ſections. * Spinoſi, ſpinous, with the tail (or beak) produced. ** Frondoſi, ſutures expanding into criſped foliations; tail (or beak) abbreviated (vulgarly called purpura). *** Varicoſi, ſutures rounded, protuberant, and thick. **** Ecaudati, without tail (or beak) and ſomewhat ſpinous. ***** Caudigeri, tail (or beak) ſubulate, cloſed, ſtraight and elongated; unarmed with ſpines. ****** Turriti, tapering, ſubulate, with the tail very ſhort.

The murices of the elder writers conſiſted for the moſt part of ſuch ſhells of the whelk or buccina kind as exhibited any conſiderable degree of aſperity or ruggedneſs on the exterior ſurface, the Latins having employed the word murex to expreſs the roughneſs of rude ſtones or walls. Many of the Linnæan murices are of that kind deſcribed by his predeceſſors under the name of purpuræ, the animals of which are ſpoken of by the ancients as being furniſhed with a tongue-like proceſs, by means of which they are enabled to perforate other ſhells, and derive ſubſiſtence from the incloſed animal. The Engliſh call the murices rocks, and the French in imitation, *rocher*.

Three genera of ſhells formed of the Linnæan murices by the continental writers, claim particular attention; theſe are faſciolaria, pleurotoma, and a genus, retained under the title of murex. The firſt of theſe conſiſts of ſuch ſhells as like the murex tulipa of Linnæus are of a ſomewhat fuſiform, or ſpindle ſhape; ſmooth or without rugoſities, and having upon the pillar two or three very oblique folds or plaits. Pleurotoma is alſo of a ſpindle form, with the aperture terminating below in a long gutter or canal, and has the lip cleft or cut off in a ſlope near the ſummit. The third or murex genus is of an oval or oblong form, canaliculated at the baſe, and having the outſide of the ſhell conſtantly beſet with prominent longitudinal ridges, and for the moſt part with tuberculations, ſpines, or fringes. We cannot refrain obſerving that this, and perhaps ſome further amendments in the Linnæan murices, were requiſite to reduce them to lucid order; it will not we think admit of any doubt that the two firſt genera before mentioned, ought not to be arranged in the ſame genus with the murices, admitting the Linnæan character of that genus as it ſtands in the Syſtema Naturæ. Linnæus, it is true, included ſhells of both theſe families among the murices, but ſurely without ſufficient attention to the generic character he had himſelf propoſed for the murex tribe.

Trochus. Animal a limax. Shell univalve, ſpiral, and ſubconic; aperture ſomewhat angular, or rounded; upper ſide tranſverſe and contracted; pillar placed obliquely.

The trochi Linnæus divides into three families; * umbilicati, &c.; umbilical, erect, and with the pillar perforated; as in the ſpecies niloticus and perſpectivus. ** Imperforati, &c.; erect, with the umbilicus cloſed; as in labio. *** Turriti, &c. turrited, with the pillar exſerted; ſhell falling on one ſide when placed on the baſe.

This is a long eſtabliſhed genus of ſhells, having been adopted by the principal conchological writers a conſiderable time before the Syſtema Naturæ of Linnæus appeared. Notwithſtanding this, we perceive no ſmall degree of difficulty ariſing in a general arrangement of ſhells from too ſtrict an adherence to this genus as the character is propoſed by Linnæus. We do not object to the trochus genus altogether; it is an excellent genus in itſelf, ſo far as relates to the greater number of the conic ſpecies, which may be readily diſtinguiſhed by their outline, but we cannot, it muſt be acknowledged, ſo eaſily reconcile our ideas to the propriety of including with theſe the turrited or tapering trochi of this writer; ſuch as, for example, in the ſpecies teleſcopium, and others in that family. Furthermore, it may be added that ſome amendment in the diſtribution of theſe ſhells is rendered the more neceſſary for the ſake of perſpicuity in the arrangement of a number of new ſpecies not ſtrictly according even with the former, and which have been diſcovered ſince the time of Linnæus.

Lamarck, and after him Latreille, conſtitute a new genus of the turrited kinds of the Linnæan trochi, under the title of pyramidella, and which they define generically, as being a turrited ſhell, with the opening entire, and ſemioval; pillar projecting, raiſed, with three tranſverſe folds, and perforated at the baſe. This genus is fully illuſtrated by the Linnæan trochus dolabratus.

The new genus pyramidella was certainly neceſſary; but beſides this, the continental naturaliſts above mentioned, have inſtituted ſome other genera from the Linnæan trochi, as ſolarium, and monodonta. The Linnæan trochus perſpectivus elucidates the character of the firſt of theſe three genera, which conſiſts in being of a depreſſed conic form, with an umbilical opening in the baſe, crenulated along the inner margin of the ſpiral volutions, and the opening or aperture almoſt quadrangular. This is the ſhell known among Engliſh collectors by the name of ſtaircaſe trochi, from a fancied reſemblance of the internal view of the umbilical opening to a well, or ſpiral ſtaircaſe. Theſe ſhells are comprehended by Linnæus in his firſt family of trochi; but we ſhould rather incline to admit them as a genus diſtinct from that tribe; the depreſſed contour of the ſhell, and ſingular ſtructure of the umbilical opening, forming an excellent generical diſtinction. The Linnæan trochus labio, and its analogous ſpecies, being of an oval or conoid ſhape, with the opening roundiſh and entire, but furniſhed with a projecting tooth, are the deſcription of ſhells of which the genus monodonta conſiſts.

Turbo. Animal a limax. Shell univalve, ſpiral, and ſolid; aperture contracted, orbicular, and entire.

The ſhells of this genus are divided into five families; * neritoidei, &c. having the pillar-margin of the aperture flat, or dilated and imperforate; ** ſolidi, ſolid and imperforate; *** ſolidi, &c. ſolid and umbilicated, or perforated; **** cancellati, cancellated; ***** turriti proprie dicti, turrited, or tapering.

The turbo genus, as it ſtands in the Linnæan Syſtema, is much too diffuſe, and comprehends ſhells ſo very remote from each other in various eſſential circumſtances, that the Linnæan ſtudent will find ſome difficulty in retaining it under its preſent form. So nearly indeed do the Linnæan turbines, and buccina approach, that the ableſt Linnæan is ſometimes unable to decide exactly to which of the two genera particular ſpecies ought to be referred. The diſſimilarity, in general appearance, is alſo very remarkable in the turbo genus. The conoid, and the tapering turbines of this writer, are altogether diſtinct, and ſhould certainly be aſſigned to different genera; and a diſſimilitude equally ſtriking prevails between thoſe which have a ſinus at the margin, and ſuch as have that part entire. In addition to theſe, we would mention the Linnæan turbines which have equidiſtant longitudinal ridges diſpoſed on the outſide of the ſhell, as in turbo ſcalaris and clathratus, as affording ſuch a very prominent diſtinction, that we cannot heſitate to conſider them as a genus of themſelves.

Helix. Animal a limax. Shell univalve, ſpiral, ſubdiaphanous, and brittle; aperture contracted, ſemilunar, or roundiſh.

This genus is divided into ſeveral families; as * ancipites, &c. angulated on both ſides, ** carinatæ, margin of the whorls acute, *** rotundatæ, whorls rounded, and umbilicated, **** rounded and imperforate, ***** turritæ, tapering, ****** ovatæ, &c. ovate and imperforate. The whole genus comprehends, according to the laſt edition of the Syſt. Nat. two hundred and fifty-two deſcribed ſpecies.

The animal of the helices ſeems to be endowed with a more perfect and lively power of motion than moſt others of the teſtacea tribe; this we have abundant opportunity of obſerving in the common land and garden ſnail which is of this genus. Before the time of Linnæus the helices were known under the more indefinite title of cochleæ, to which family the neritæ and ſeveral other natural families were alſo referred.

Late writers divide the Linnæan helices into a number of new genera, as janthina, bulimus, lymnæa, melania, planorbis, and helix. See Latreille, Olivier, &c.

Nerita. Animal a limax. Shell univalve, ſpiral, gibbous, flattiſh at bottom; aperture ſemi-orbicular, or ſemilunar; pillar lip tranſverſely truncated and flattiſh.

The Linnæan neritæ are divided into three families, * umbilicate, ** imperforate, with the lips toothleſs, *** imperforate, with the lips. No leſs than ſeventy-two ſpecies are deſcribed in the Syſtema Naturæ under theſe three families.

The nerita genus of Lamarck, Latreille, and other late writers, conſiſts of thoſe Linnæan ſpecies, which are ſemigloboſe, flattened at the baſe, and not umbilicated; with the opening entire and ſemi-circular; and the pillar ſomewhat tranſverſe, truncated, and often denticulated. Nerita exuvia of Linnæus is of this kind. The genus natica (natice) of thoſe writers, comprehend the umbilicated neritæ, ſuch as the ſpecies canrena, and its analogous kinds. The naticæ are ſubgloboſe, umbilicated, with the left margin callous near the umbilicus: mouth or opening of the ſhell entire; pillar oblique, and not denticulate.

Haliotis. Animal limax. Shell ear-ſhaped, dilated, ſpire lateral, and nearly concealed, and a longitudinal row of orifices along the diſk or ſurface.

Few ſpecies of this genus were known to Linnæus, and in the reference of theſe, he was peculiarly attentive to the characteriſtic longitudinal ſeries of orifices ſo conſpicuous in this genus. It was for this reaſon he referred the helix haliotoidea to the helices, rather than the haliotis tribe; the ſhell being deſtitute of this ſtriking character, though, in every other reſpect, it appertains more ſtrictly to this haliotis than the helix genus. After this we cannot think Gmelin adviſeable for having admitted the imperforate ſhells, his haliotis imperforata and perverſa, into this genus. It would have been perhaps better, even in that ſyſtem, to have conſtituted a new family for their reception; he conceived the introduction of a new genus an innovation. Chemnitz indeed calls the firſt of theſe an haliotis, but its impropriety is not leſſened by that circumſtance.

One of the imperforate kinds, the haliotis imperforata of Gmelin, was previouſly deſcribed by Heblins, under the new generic title of ſtomatia, a genus adopted ſince by Lamarck,

marck, Latreille, and various other writers; and which we cannot heſitate to admit as highly neceſſary. The diſtinctions between theſe two genera are ſufficiently characteriſtic. Stomatia has the ſhell of an oval form, and ear-ſhaped, with the ſpire prominent; the aperture ample, entire, and longer than its breadth; diſk imperforate, or without orifices. Haliotis ſhell flat, ear-ſhaped, with the ſpire very low, and almoſt lateral; aperture very ample, and longer than its breadth, and entire; and the diſk pierced with orifices diſpoſed in a line parallel with the left margin.

Liſter, in his "Hiſtoria Conchyliorum," places the haliotis, or ſea-ear tribe, among the turbinated ſhells, between the nerita and trochus; the ſame mode of arrangement is obſerved in his work "De Animalibus Angliæ," where he ſays it is ſpiral at the clavicle, in the ſame manner as other turbinated ſhells, and is therefore placed erroneouſly by ſome among the ſimple ſhells. Gualtieri ranks them among ſnails with depreſſed or flattened ſpires; Adanſon, in the firſt family of ſpiral ſhells; Da Coſta immediately after the patellæ, his firſt genus of ſimple ſhells, and Lamarck between the teſtacelle, which follows the helices and neritæ, and the vermiculaire or ſerpula.

Some writers admit it as a collateral character of the haliotis, that the inſide is always of the fineſt pearl, and pearls are oftentimes produced in theſe ſhells. The perforations vary in number in different ſpecies. It has been obſerved, that the animal always cloſes one of thoſe holes towards the ſpire, whenever he opens another towards the head as he grows bigger, and by that means that the number of openings are invariably the ſame in different individuals of the ſame ſpecies. Shells of this genus are very rarely diſcovered foſſil; we much queſtion if any of thoſe deſcribed by writers are truly of this genus.

PATELLA. Animal a limax. Shell univalve, ſub-conic, and without ſpire. Linn.

Theſe are the limpets, and are ſo named from their reſemblance to a little plate, or patella, and are more or leſs conic without, and concave within. Some have the apex or top entire; others perforated: the chambered limpets are diſtinguiſhed by a peculiar kind of projecting proceſs, or lip within; moſt have the margins entire, but ſome have an indent or fiſſure in that part; and again others are ſo completely ſpiral or wreathed in their exterior appearance that they reſemble rather the trochi, or top ſhells, than the limpet. Linnæus, in order to compriſe ſhells ſo very diſſimilar in appearance under one genus, found it neceſſary to conſtitute no leſs than five diſtinct ſections or families for their reception. Theſe he arranges in the following order.

* Labiatæ, &c. furniſhed with an internal lip; ſhell entire.

** Dentatæ, &c. with the margin angulated, and toothed.

*** Mucronatæ, &c. with the pointed tip recurved.

**** Integerrimæ, &c. very entire, and not pointed at the tip.

***** Perforatæ, &c. with the crown perforated.

Lamarck, as being one of the lateſt writers on this ſubject, deſerves particular attention; he divides the Linnæan patella into ſix diſtinct genera, which he calls patella, fiſſurella, emarginula, concholepas, crepidula, and calyptræa.

The ſhells retained under the old name of patella (patelle) are defined generically as being univalve, without ſpire, oval, or ſuborbicular, ſhield-form, or bonnet-ſhaped, concave and ſimple beneath, with the ſummit entire, and margin without fiſſure, as exemplified in patella teſtudinaria, in the fourth Linnæan family. Fiſſurella (fiſſurelle) has the ſhell ſhield-form, without any kind of ſpire, concave beneath, and at the ſummit an oval or oblong aperture. The fiſſurellæ correſpond with the fifth of the Linnæan families perforatæ, and with the genus formed by Da Coſta under the name of pierced limpets or maſks, in his "Elements of Conchology." The little ſlit limpet, patella fiſſura of Linnæus, very clearly illuſtrates the genus emarginula (emarginule), of Lamarck; the genus is diſtinguiſhed by the ſhell being of a conic form, concave beneath, and having the poſterior margin cleft. The concholepas has the ſhell univalve, oval, convex above with the ſummit obliquely inclined upon the left margin; the cavity within ſimple; and two teeth and a ſinuoſity at the baſe of the right margin. This genus is exemplified in the concholepas peruviana of Favanne, and buccinum lepas of Bruguiere. Some other writers admit it as a family of the limpets which they diſtinguiſh ſimply by having the beak produced and ſomewhat twirled or crooked. The crepidula (crépidule) of Lamarck is of an oval, or oblong form; with the ſummit inclined upon the margin, and a partial ſimple diaphragm or diviſion in the cavity. The Linnæan patella porcellana is of this genus. The calyptræa (calyptrée), is of the chambered kind, appertaining to the firſt of the Linnæan families, and is ſufficiently explained by the Linnæan patella equeſtris. The ſhells of this kind are of a conoid form with the ſummit vertical, entire, and pointed, and the cavity furniſhed with a thin plate, or tongue-like proceſs in the centre, which is either detached or connected to one ſide of the ſhell, and runs in a ſpiral direction.

DENTALIUM. Animal a terebella. Shell univalve, tubular, ſtraight, or ſlightly curved, with the cavity open at both ends, and undivided. Linn.

The ſimplicity and preciſion of the generic character of dentalium merits commendation, and, although ſome late writers on the continent ſeem too faſtidious to admit it, we deem it unexceptionable. The ſhells of this kind are known in England by the name of tooth ſhell. (Donov. Brit. Shells.) We have few ſpecies, and thoſe are principally of the minuter kinds, in this country. Gmelin enumerates altogether twenty-one ſpecies of this genus, ſome of which are found only in a foſſil ſtate.

SERPULA. Animal a terebella. Shell univalve, tubular, and adhering. Often ſeparated internally by diviſions at uncertain diſtances.

By the introduction of a few particular ſhells the Linnæan ſerpulæ are rendered altogether incongruous. The genus, as now retained, is extremely vague; and which, indeed, is neceſſary in order to compriſe the whole of the ſpecies deſcribed by Linnæus under this general head. Nothing abſolutely certain is eſtabliſhed for its character, except its being an univalve ſhell, a circumſtance common to the greater part of the ſhell tribe, and its being tubular without a regular ſpire, which is no leſs applicable to the dentalia, the teredines, and if, like Linnæus, we admit the genus to be really of the teſtaceous tribe, the ſabellæ alſo. What then remains to fix the character of a ſerpula? that it adheres to other bodies, but even this is not always the caſe; and beyond this we are again left in doubt, its character being confeſſedly indeciſive and local, "ſæpe iſthmis integris paſſim intercepta," Linn. There are ſometimes internal diviſions at uncertain diſtances in theſe ſhells, but what can we infer from theſe in conſtituting a generic character: theſe diviſions are in the firſt place concealed within the ſhells when entire, and are only to be diſcovered by deſtroying them! and can this be conſidered as a character well calculated to afford a generical criterion? Nor is this all, theſe internal diviſions are by no means conſtant; they are not as in the nautili and other regularly formed chambered ſhells placed at equal intervals, neither are they pierced by a ſiphunculus, or pipe-like receptacle communicating from chamber to chamber for the reception of the linear body of the animal inhabitant; the creature muſt remain in the ſingle chamber or encloſure, having no means of extending itſelf into the reſt of the ſhell. And beſides this, the concamerations above-mentioned do not ſeem conſtant to any particular ſpecies, but depend on the age of the ſhell, and appear to be formed progreſſively at various intervals as the animal from various cauſes or its increaſe of growth finds it neceſſary to form a larger dwelling. In this caſe the deſerted chamber laſt occupied being no longer uſeful is cloſed up, to render its new habitation more compact. We now advert only to particular ſhells; there are many ſpecies which do not exhibit ſuch a concamerated ſtructure.

One of the firſt writers upon this ſubject, after the time of Linnæus, was Da Coſta, who in his "Elements of Conchology" takes occaſion to notice the manifeſt impropriety of uniting in the ſame genus the ſhell known by the Linnæan ſtudent under the name of ſerpula penis, and the ſimple vermiculi.

He propoſes to obviate the difficulty by conſtituting two genera, the *vermiculi*, or tubular worm ſhells, which have no fixed or regular form, as the common vermiculi, (ſerpula vermicularis, Linn.); and *pencilli*, or thoſe worm-ſhells which, in the whole, or any eſpecial or particular part, have a determinate regular ſhape or ſtructure. Of this laſt genus, he obſerves there are few ſpecies; the watering pot (ſerpula pluis, Linn.) from the Eaſt Indies is the chief kind, and when perfect is much valued. The propriety of dividing theſe families of ſhells is well conceived, but the diſtinctions are leſs happily defined than might be expected. The ſuggeſtion, however, of this writer has been improved upon by the later French naturaliſts. The genus arroſoir or pencillus of Lamarck is the pencilli of Da Coſta; and yet, in truth, we ſhould add, that though the genus was laid down by Da Coſta, we may trace it to Argenville, who had previouſly, nay, even before the time of Linnæus, deſcribed the watering-pot ſhell under the title of pencillus marinus. The genus arroſoir, or pencillus, as defined by Lamarck, is a good one, and the ſame may be truly ſaid of the ſiliquaria of Davila, a genus exemplified in the Linnæan ſerpula anguina, which is diſtinguiſhed by having a longitudinal ſubarticulated opening or cleft, extending throughout the whole length of the ſhell. The concamerated ſerpulæ, we have ſeen, are not to be regarded as generically different from the reſt.

The vermiculi of Gualtieri include the Linnæan turbo ſcalaris, a rare ſpiral ſhell, better known in England by the name of wentletrap, and which is eſteemed of conſiderable value on account of its rarity. This writer places it with the vermiculi, becauſe, as he obſerves, the ſpires of the ſhell are not produced from or ſupported by a pillar, as is conſtantly the caſe in turbinated ſhells, but poſſeſs, on the contrary, the true character of the ſpiral worm ſhells; and there is certainly much truth in the ideas of Gualtieri, though we do not at the ſame time perceive the abſolute neceſſity of removing it to this genus, and we ſhould anxiouſly and moſt ſcrupulouſly avoid any needleſs innovation. Laſtly, we ſhall mention that the author of the "Teſtacea Britannica" propoſes as an amendment in the ſerpulæ, to divide them into two diſtinct genera; the ſerpula he retains under the old Linnæan character, "ſhell univalve, tubular, adhering, or affixed to other bodies; in ſome ſpecies divided into cells." The other he calls *vermiculum*, and defines "ſhell univalve, ſhape various; not attached, or adhering to other bodies." This we believe muſt in candour be admitted as more vague and indefinite than even the Linnæan diſtinction, and by the laxity of expreſſion may as well apply to the whole tribe of univalve ſhells, the adherent ſerpulæ excepted, as to the particular family called vermiculum. But though we diſapprove of the character aſſigned, we perfectly agree with the ingenious author as to the propriety of ſeparating the adhering kinds of ſerpula from thoſe ſpecies which conſtantly occur detached.

TEREDO. Animal a terebella, furniſhed with two calcareous, hemiſpherical valves, or maxillæ, truncated before, and two others of a lanceolate form; ſhell tapering, flexuous, and penetrating wood.

The animal inhabiting this ſhell is a terebella of a particular kind; the body being of a ſoft and gelatinous nature, but having the head provided with an inſtrument of a calcareous ſubſtance, which performs the office of an augre, and enables the worm to penetrate the hardeſt oak. The moſt deſtructive of the animals of this genus is the teredo navalis, which penetrates the bottoms of ſhips. It was originally imported from India into Europe about ſeventy years ago. Sellius, in the year 1733, publiſhed a treatiſe on this ſubject under the title of "Hiſtoria Naturalis Teredinis, ſeu Xylophagi marini Tubulo-conchoidis." It was afterwards deſcribed and figured by ſeveral writers, and among others by Baſter, in the Philoſophical Tranſactions, vol. lxi. It is now too well known by the name of *ſhip-worm*. See Donov. Brit. Shells.

Three ſpecies only of this ſingular genus have been yet diſcovered, and which are named navalis, utriculus, and clava. Favanne and Guettard divide theſe ſhells into two genera, teredo (taret) and fiſtulana; the ſhell of teredo is diſtinguiſhed as being tubular, cylindrical, and open at both ends, lower orifice furniſhed with two lozenge-ſhaped valves, and the upper with two ſpatulous opercules. Fiſtulana is a genus compoſed of a ſingle ſpecies, teredo clava, Gmel.: the ſhell is tubular, clavated at one end, open at the ſlender extremity, and containing in the cavity two non-adherent valves. This laſt is called by Favanne, fiſtulana cornicula, and fiſtulana gregata by Guettard.

SABELLA. Animal a nereis, with ringent mouth, and two thicker tentacula behind the head: ſhell tubular, compoſed of particles of ſand, broken ſhells, and vegetable ſubſtances, united to a membrane by a glutinous cement.

The ſabella, according to Linnæus, is inhabited by an animal of the nereis kind. Some of theſe animals were known among the old writers under the name of ſea ſcolopendiæ. Since the time of Linnæus, the number of ſpecies has been greatly augmented by the diſcoveries of Pallas, Fabricius, Müller, and others, and the nature of thoſe animals become better underſtood; in conſequence of which, they have been diſcovered to be the habitations not only of the nereis, but likewiſe of the amphitrite and terebella genera. We ſpeak of the marine kinds: with reſpect to ſeveral of the ſuppoſed ſpecies of ſabella found in freſh water, it is accurately determined they are not of this race of animals, but the larvæ of ephemeræ, phryganeæ, and other inſects, which conſtruct cylindrical cells of extraneous matter, in which they reſide while they remain in that ſtate in the water. Some naturaliſts, in order to avoid confounding theſe larvæ with the true ſabella, have cautiouſly omitted the whole; and we indeed ſuſpect, that although they may continue to be retained by the Linnæan ſtudent among the ſhell tribe, they will be expunged, or many of the ſpecies at leaſt, by future ſyſtematiſts. The Gmelinian ſyſtem comprehends 25 ſpecies of ſabella, the freſh-water kinds, deſcribed by Schroetter, included.

The marine ſabellæ ſhells are compoſed chiefly of ſand and the fragments of ſhells; thoſe of the ſuppoſed ſabella found in freſh water, either of ſmall fragments of vegetables, or the broken ſhells of teſtaceous vermes, thoſe of the helix tribe eſpecially.

Having preſented the reader with a detailed view of the Linnæan ſyſtem of conchology, we ſhall next proceed as before to ſpeak of the other principal writers on the ſubject, as nearly in chronological order as circumſtances will permit.

The third volume of the extenſive and coſtly work of Seba "Deſcriptio Theſauri Rerum Naturalium," was produced at Amſterdam in 1758. This part treats on marine ſubjects generally, as cruſtaceous and teſtaceous animals, corals, &c.; and contains, beſides plates in other departments, ſixty-one elucidatory of conchology. As a book of reference to the more ſtriking and well-known kinds of ſhells, the work of Seba poſſeſſes merit: it has been obſerved, and with much truth, that this valuable publication might however have been rendered leſs expenſive by the omiſſion of a number of figures, which conſiſt merely of repetitions, and alſo the ſpecimens of art abſurdly introduced, ſuch as the fanciful decorations on the ſhells of the nautili, and the examples of "ſhell work," on which a profuſion of engraving is unneceſſarily expended.

In the "Hiſtory of Cornwall," Dr. Borlaſe preſents us with a plate of ſhells containing about thirty ſpecies; the deſcriptive matter is ſlight, and is principally copied from ſome of the oldeſt writers on the ſubject. This was publiſhed in folio in London, A.D. 1758.

The magnificent work of Francois Michael Regenfus, "Choix de coquillages et de cruſtacés," appeared at Copenhagen, under the patronage of the king of Denmark, in the ſame year as the preceding. The work compriſes twelve coloured plates in imperial folio, and each plate comprehends twelve ſhells. The deſcriptions, which are written both in the French and Daniſh language, are the joint labour of profeſſor Kratzenſtein and Dr. Aſcanius. It has been lamented that the talents of this artiſt were not employed on ſubjects better deſerving of elucidation, as thoſe which are figured by Regenfus fall daily under the notice of the moſt humble collectors. A ſecond volume was begun, and conſiderable progreſs made in it before the year 1776; but as the artiſt is no more, the undertaking is in all probability relinquiſhed. Twelve plates deſigned for the ſecond volume are poſſeſſed by ſir Joſeph Banks, and which include ſhells of greater rarity than thoſe inſerted in the firſt volume.

We have already adverted to the "Claſſes Conchyliorum" of Carolo Auguſto de Bergen, publiſhed at Nuremberg in 1760. This little treatiſe contains a compendious view of the principal ſyſtems of conchology which had then appeared, under the heads of "Methodi Univerſales," and "Methodi Particulares," with conciſe prefatory ſtrictures on each. Theſe remarks of Bergen have evidently furniſhed later writers with many uſeful criticiſms on the ſeveral works that fall within the compaſs of his view, and may, upon the whole, be thought far preferable to many more elaborate obſervations that have ſince appeared on the ſame ſubject.

The "Amuſement Microſcopique" of Ledermuller relates to minute ſhells, and contains many figures. The firſt part was publiſhed at Nuremberg in 1764, and in 1766 and 1768 two other parts of the ſame work.

Davila's "Catalogue Syſtematique et Raiſonné des Curioſités de ſon Cabinet" was printed at Paris, in 1767, in three volumes octavo, preparatory to the diſperſion of his collection in the following year. The firſt volume treats entirely of ſhells, and contains twenty-two plates of the rarer ſpecimens in his cabinet, many of which are ſcarce even at this day. This work affords much intereſting information, though it is to be conſidered only as a ſale catalogue. The ſame year a ſimilar production, "Catalogue Syſtematique des Coquillages de Arnold Leers, de Rotterdam," appeared at Amſterdam, as an annunciation of the ſale of his valuable collection. This was written by Mr. F. C. Meuſchen, German envoy at the Hague, and contains a ſheet ſyſtem of ſhells.

The work of Geoffroy, "Traité des Coquilles, tant fluviatiles que Terreſtres, que ſe trouvent au Environs de Paris," was printed in 1767, and forms a valuable acquiſition in this department of ſcience. Three plates engraven by Ducheſne, contain figures of forty-ſix ſhells deſcribed by Geoffroy.

A curious and intereſting paper by Heriſſant, occurs in the Mem. de l'Acad. des Sciences, for 1768, entitled, "Eclairciſſemens ſur l'Organization juſqu' ici inconnue d'une Quantité conſidérable de Productions Animales, principalement de Coquilles des Animaux," with eight illuſtrative plates, three of which relate to ſhells. In the ſame year the "Memoire ſur le Coquillage appelé Datte en Provence" of A. D. Fourgeroux de Bondaroy, was inſerted in Mem. Etrang. de l'Acad. Roy. de Sc. together with a plate elucidatory of the ſubject, which is the Linnæan mytilus lithophagus.

Cotte's obſervations on the phyſiology, &c. of the ſnail tribe, occur in the "Journal de Sçavans" for 1770, and in the "Journal de Phyſique les Délices des Yeux, et de l'Eſprit" of Knorr, completed in 1773, conſiſt of ſix parts, and altogether contain 978 figures of ſhells. The author was a painter at Nuremberg, and his publication commenced in 1760; but not living to finiſh the undertaking, the laſt part was brought forward by his executors. Knorr had collected materials for another teſtaceological work, his "Deliciæ Naturæ ſelectæ," which was afterwards prepared for public view under the direction of Müller and De la Blaquière.

Another conchological work, of ſtill greater extent, "Neues ſyſtematiſches Conchylien-cabinet," was in a progreſſive courſe of publication at Nuremberg, about the ſame period. The firſt part appeared in 1769, another in 1771, and a third in 1777. Theſe conſtitute the firſt three volumes, which were all its author, Martini, lived to complete. Seven volumes have been ſince added by F. H. Chemnitz. The body of the work is written in the German language; the embelliſhments conſiſt of 366 plates, and exhibit a number of figures on each plate. It is highly probable this work will never be extended beyond its preſent limits; Chemnitz being dead, and his collection of ſhells, which was very copious, having been diſperſed within the laſt four years by public ſale. The catalogue of ſale bears date Feb. 7, 1803, it was drawn up by H. S. Holten, in a ſmall duodecimo, entitled, "Enumeratio ſyſtematica Conchyliorum J. H. Chemnitzii," &c.

Schröter is the author of many treatiſes on the ſubject of ſhells, and which appear to be little known. He has in particular diſtinguiſhed himſelf by his obſervations on the river ſhells of Thuringia; the ſource from whence Gmelin has obtained many of the new-ſpecies deſcribed in his edition of the Syſtema; the ſabellæ of this writer are very numerous. See his "Die geſchichte der Fluſſconchylien, mit vorzüglicher rückſichte auf diejenigen welche in den Thüringiſchin giſchen waſſern leben," 1779. This was preceded by a ſmall publication on the land ſhells found chiefly in the neighbourhood of Thangelſtadt, "Verſuch einer ſyſtematiſchen abhandlung uber die Erdkonchylien um Thangelſtadt." A later production of this writer's is the "Einleitung in die Conchylien kenntniſs nach Linné," publiſhed in three volumes octavo, 1783—1786, and which to the German ſcholar forms a valuable introduction to the ſtudy of conchology.

The "Zoologiæ fundamenta" of Martinus Thrane Brunnich, was publiſhed in 1772, and relates in a partial degree to ſhells.

In the "Vermium terreſtrium et fluviatilium Hiſtoria" of Müller, we are preſented with an arrangement of land and river teſtaceous animals diſpoſed according to the characters of the animals themſelves inſtead of their ſhells. The firſt volume was begun in 1773, and the ſecond in the year following. The teſtaceological productions of Denmark are deſcribed in the "Zoologia Danica" of this author.

The "Viaggia in Dalmazia," or travels in Dalmatia, by Albert Fortis publiſhed at Venice in 1774, contains a few figures elucidatory of thoſe ſhells which he found in the Porto di Bua.

The "Elements of Conchology," by Da Coſta, was publiſhed in 1776. This work preſents us with a new arrangement of ſhells, and beſides contains ſome judicious obſervations on the claſſification of Linnæus, and ſome other writers; which latter, in our opinion, deſerve more attention than his ſyſtem of ſhells. The "Elements" of this writer is one of the moſt inferior of this author's works. His "Britiſh Conchology," publiſhed in 1778, is more valuable, though it does not take a ſufficiently extenſive view of the Britiſh teſtacea. Da Coſta had intended to publiſh a ſecond edition of theſe with conſiderable improvements; the collection of materials, and the MS. for which are in the poſſeſſion of Mr. Donovan, and have been in part incorporated into his "Natural Hiſtory of Britiſh Shells." The great forte of Da Coſta appears to be in the antediluvian race of ſhells, and other extraneous foſſils, and in the more uſeful departments of mineralogy, or what he denominated native foſſils. Upon theſe ſubjects alone, no leſs than ten folio volumes of unpubliſhed manuſcripts are preſerved at this time in the extenſive collectanea of original MS., &c. formed by Mr. Donovan, and which are intended to be placed in the library of his muſeum.

Among the few teſtaceological works noticed by Da Coſta, in the introduction to his "Elements," he ſpeaks of "a new and anonymous conchology, began to be publiſhed in this metropolis, in 1770, in folio, illuſtrated with copper plates." "It was intended (he obſerves) to be a general natural hiſtory of ſhells, and to include figures of all the known ſpecies, common as well as rare, beautiful or otherwiſe, and ſome copies were deſigned to be accurately coloured for the uſe of the curious. This anonymous production was, to our knowledge, written by Da Coſta, and was the joint undertaking of himſelf and Mr. George Humphrey, by the latter of whom moſt of the ſhells were furniſhed that are deſcribed in this work. The numbers of this work that were publiſhed comprehend the firſt three families of his ſyſtem, limpet, ſea-ear, and ſerpula.

The publication of Ignaz Edler von Born, the celebrated mineralogiſt entitled "Index Rerum Naturalium Muſaei Cæſarei Vindobonenſis" preſented the public in 1778 with the deſcription of the ſhells preſerved in the muſeum of the empreſs queen at Vienna; and was undertaken at the expreſs command of her imperial majeſty. Two years after the baron publiſhed his "Teſtacea Muſei Caeſarei Vindobonenſis," as a ſplendid illuſtration of his former work; this contains about two hundred coloured figures delineated in eighteen folio engravings.

The early editions of the "Britiſh Zoology," as it is entitled by Mr. Pennant, though in reality it embraces only an inconſiderable portion of the zoological productions of Britain, include none of the teſtaceous tribe: theſe were added, in a fourth volume publiſhed in 1778. This volume contains an enumeration of 163 ſpecies of ſhells with conciſe deſcriptions, and 56 plates exhibiting figures of nearly all that are deſcribed. Dr. Maton obſerves in his comments on this work that "moſt of the plates are valuable for reference, but ſome of them are executed leſs carefully than could have been wiſhed. In the deſcriptive part (ſays the doctor) the author has tranſlated pretty cloſely the ſpecific characters, given by Linnæus, whenever they could be had, but there are ſeveral ſpecies of which the former is to be looked upon as the firſt deſcriber. It is very remarkable, however, that he ſhould have wholly omitted others which had been noticed by Liſter and Petiver, and which are unqueſtionably natives of our iſland." The number of Britiſh ſpecies of teſtacea known to us at preſent amount altogether to ſeveral hundreds more than Mr. Pennant was acquainted with, and it is our knowledge of theſe which renders his catalogue of little moment. But we ought in candour to allow that conſidering the very low ebb of natural ſcience in this country at the period Mr. Pennant wrote, his work is a reſpectable performance: we mean with regard to the number of ſpecies contained. The deſcriptive matter certainly betrays great want of information, as well as ſcience: many of the ſynonyms are miſapplied, and the names erroneous.

The "Obſervations ſur les moules" in the "Journal de Phyſique," 1779, is from the pen of a lady, Maſoon le Golſt, and relates to the reproduction of parts of muſcles. Dicquemare treats upon the locomotive faculty of oyſters in the ſame volume of this journal "Sur la Faculté locomotive des huitres," p. 241. tom. 28.

In 1780 the "Fauna Groenlandica," of Otho Fabricius was printed at Leipſic. This work contains the deſcription of fifty ſeven ſpecies of ſhells found in Greenland, among which are a number not previouſly obſerved by writers. Fabricius pays conſiderable attention to the ſtructure and habits of the animal as well as the ſhell.

The "Zoophylacium Gronovianum," a deſcription of the rich muſeum of L. T. Gronovius ſenator at Leyden was publiſhed in 1781. There are in this work a ſcientific deſcription of 589 ſpecies of ſhells, and among the plates, two appropriated to the illuſtration of the rarer kinds.

Molina's "Saggio ſulla ſtoria naturale del Chili," or natural hiſtory of Chili, comprehends deſcriptions of the ſhells obſerved by this writer in that part of South America. The work was printed in octavo, at Bologna in 1782.

A ſmall octavo tract was publiſhed at Naples in 1784 entitled "Deſcrizione di una nuova famiglia, e di un nuovo genere di Teſtacei, trovati nel littorale di Catania, con qualche oſſervazione ſopra una ſpezie di oſtriche," by M. Gioeni. The ſuppoſed new genus of ſhells which occurred to the notice of Gioeni on the ſhores of Catania was no other than the hard teſtaceous ſubſtance found in the gizzard of bulla lignaria, a ſimilar organ to which we have ourſelves found in the gizzard of bulla aperta. Some years paſſed before this miſconception was detected: it had been really conſidered as a ſhell by profeſſor Retzius from whom it obtained the name of triola Gioenii; and it is arranged alſo in the ſyſtem of Bruguiere under the name of gioenia ſicula. M. Draparnaud claims the merit of having firſt aſcertained the real nature of this teſtaceous ſubſtance, an account of which he inſerted in the Nouv. Journ. de Phyſique. We ſhould add that the ſame article is deſcribed and illuſtrated with figures in the ſecond volume of the Linnæan Society by Mr. G. Humphrey, aſſociate.

A variety of new and very curious experiments by the indefatigable Spallanzani on the reproduction of the head of the common ſnail is recorded in two memoirs, the firſt of which was publiſhed in 1782, the other in 1784. See "Riſultati di Eſperienze ſopra la Reproduzione della Teſta nelle Lumache Terreſtri," Mem. della Soc. Ital. t. 1. p. 581.—t. 2. p. 506

The ſplendid work on ſhells by Martyn entitled the "Univerſal Conchologiſt," was begun in the year 1784, and continued to be publiſhed at uncertain intervals till 160 plates appeared, when its progreſs was finally impeded. This work commenced with the nondeſcript ſhells collected in the different voyages of the Engliſh circumnavigators in the South Seas; many of which are ſtill eſteemed valuable, while others, as may be imagined from our more habitual intercourſe at this time with the ſouthern hemiſphere, are become common. As a ſcientific work, this performance will be found altogether defective, and it is beſides too barren of general particulars, to render the ſubject pleaſing to the common reader. Much greater praiſe is due to the plates, which are the productions of Grozier, and many other artiſts, and are for the moſt part well executed; it may be indeed added that they are the repreſentations of objects in themſelves ſo beautiful as to afford the artiſt every facility in the diſplay of talent. A number of the original ſpecimens are in the cabinets of Mr. Wood, apothecary, Mrs. Forſter, and others in London.

A ſmall quarto treatiſe embelliſhed with three plates, the joint labour of Mr. W. Boys, and Mr. G. Walker, appeared in London in 1784. The work treats only of microſcopic ſhells, and the reſearches of its authors were confined to the ſandy ſhores of Sandwich as the title indicates "Teſtacea minuta rariora nuperrime detecta in arena littoris Sandvicenſis." It is dedicated to the late ducheſs of Portland.

In the Philoſophical Tranſactions for 1786 is "an account of ſome minute ſhells, either not duly obſerved, or totally unnoticed by authors." This is illuſtrated with three plates and is the production of the rev. Mr. Lightfoot, the learned author of the "Flora Scotica," to whom the world is ſo highly indebted for his indefatigable inquiries reſpecting the Britiſh fuci and confervæ.

In 1786, C. L. Kämmerer deſcribed the collection of the hereditary prince of Schwarzburg-Rudolſtadt. This catalogue is in the German language, and is embelliſhed with twelve plates; it bears the title of "Die Conchylien in Cabinette der Herrn. Erb.—Prinzen von Schwartzburg-Rudolſtadt. An appendix, with four additional plates, was publiſhed at Leipſic in 1791, under the title of "Nachtrag zu der Conchylien un Fürſtlichen Cabinette zu Rudolſtadt."

The "Journal de Phyſique" for 1787, contains a deſcription accompanied with figures of chiton ſquamoſus by Lefebure des Hayes.

In the Tranſactions of the Ruſſian Academy, for the year 1787, we find a memoir on teſtaceology, entitled "Marina varia, nova, et rariora," by profeſſor Pallas. The ſubjects treated of are ſerpula ſpirillum, lepas carioſa, pholas teredula, chiton amiculatus, and helix coriacea. This author had previouſly diſtinguiſhed himſelf by his critical writings on conchology, both in his "Spicilegia Zoologica," which appeared in 1780, and his "Miſcellanea Zoologica," publiſhed ſome years before.

Retzius in the ſame year printed his "Nova Teſtaceorum Genera,", a ſmall work in quarto, in which many alterations and improvements on the Linnæan ſyſtem of conchology are projected. It was previouſly the ſubject of an inaugural diſſertation at Lund. Retzius was likewiſe the author of a deſcription of Venus lithophoga, publiſhed in the Memoirs of the French Academy for 1786.

Cordiner's work of "Remarkable Ruins and Romantic Proſpects of North Britain," appeared in numbers, and beſides the views compriſes ſome plates of natural hiſtory, among which are a few of the more remarkable ſpecies found on the coaſt of Scotland, grouped with a variety of other marine productions. Antiquity is however the leading feature of this work. Only part of this production appeared in 1788; ſome additions have been made to it ſince that time.

In the year 1789, Bruguiere, the well known traveller in the eaſt, commenced the teſtaceological part of the grand work, carried on in France, under the title of "Encyclopédie Méthodique," but unfortunately for the cauſe of ſcience, this ſkilful naturaliſt lived only to complete the firſt volume, which does not go beyond the letter C. of the article *vers* (worms). The prefatory matter to this volume contains the method of an arrangement he intended to purſue, founded principally upon that of Linnæus, with ſuch additions and deviations only, as he conceived to be required by the diſcoveries of other naturaliſts ſince the publication of the Linnæan Syſtema. This is the principal, though not the only production on the ſubject of conchology, Bruguiere ſubmitted to the world.

A pleaſing variety of beautiful and curious ſpecies of teſtaceous tribes, chiefly the extra-European kinds, have been introduced, at various times, to the notice of the Engliſh reader, through the medium of that well known periodical undertaking the "Naturaliſt's Miſcellany," of Dr. Shaw. We are not a little ſurpriſed indeed to obſerve, that the greater number of univalve ſhells in this work are reverſed in the plates, and are therefore likely to miſlead the incautious obſerver into a perſuaſion, that they are in reality heteroſtrophous. This work commenced in 1790, and ſtill continues in a progreſſive courſe of publication.

The "Zoologia Adriatica," of Abbé Olivi, printed in 1791, contains an account of the ſhells found in the gulf of Venice, with a ſeries of engravings, to illuſtrate ſome of the more remarkable ſpecies. In the "Ann. de Chimie," for the ſame year, M. Vauquelin treats of the reſpiratory proceſs in the helix pomatia, and proves in the courſe of his obſervations, that the vermes require vital air for the excitement of their pulmonary ſyſtem as well as other animals. The ſpecies above mentioned (according to this author) will reſpire azotic and carbonic acid gas, as long as any oxygen remains combined with either. The "Obſervations ſur la génération des Buccins d'Eau douce," by M. Ribaucourt, inſerted in the "Journ. d'Hiſt. Nat." for the ſame year, tend to prove that all the ſpecies of that tribe are viviparous. The laſt we have to mention in this year are the papers of M. Cuvier, the celebrated comparative anatomiſt. Theſe relate to the anatomy of the animal of the Linnæan patella vulgaris, and unguis; and the bulla aperta, and are to be found in the "Annales du Muſeum National."

The firſt volume of "Teſtaceographia ac Zoophytographia parva et microſcopica," by Am. Soldani, is dated 1789; a ſecond volume appeared in 1795. The microſcopic ſubjects, deſcribed by this writer, are principally ſhells diſcovered by himſelf at Porto-Ferrara; the iſland del Giglio; on the ſhores of Caſtiglioncello, la Follonica, &c. No leſs than 148 plates embelliſh this work, in which the ſhells are repreſented both of their natural ſize and magnified.

A number of minute, or microſcopic ſhells, diſcovered by the late Mr. Adams, on the coaſt of Pembroke, are deſcribed by that ingenious collector in the third and fifth volume of the Tranſactions of the Linnæan Society, in which will be alſo found two plates, containing figures of the ſhells deſcribed.

Among the “Obſervations ſur les Coquilles,” inſerted in the “Journ. d'Hiſt. Nat.” for 1792, and in the “Prodrome d'une nouvelle Claſſification des Coquilles.” Mem. Soc. d'Hiſt. Nat. An. 7, the curious reader will find much intereſting matter relative to the teſtaceological ſyſtems of Linnæus, and Bruguiere, and alſo a ſketch of that propoſed by their author, M. Lamarck. Theſe were the prelude to his more important undertaking “Syſtême des Animaux ſans Vertebres,” in which we meet with a new arrangement of teſtaceology more comprehenſive and ſatisfactory than has perhaps hitherto appeared upon this intereſting ſubject.

The “Teſtacea Microſcopica aliaque minuta ex Generibus Argonauta et Nautilus ad Naturam picta et deſcripta,” publiſhed at Vienna in 1798, is the joint production of L. A. Fichtell and J. P. C. Moll. It treats principally on the minute ſhells of the argonauta and nautilus genera, and contains, beſides the deſcriptions in the Latin and German languages, accurate figures of a great number of ſpecies, among which are many that eſcaped the obſervations of Plancus, and every other writer.

Mr. Hutchinſon's new and enlarged edition of the “Hiſtory of Dorſetſhire,” includes a catalogue of the birds, ſhells, and more rare plants of that county, by Dr. Pultney. The teſtaceological part of this catalogue is that which intereſts us in the preſent detail. Dr. Pultney beſtowed conſiderable attention on this department; his remarks on the Linnæan genera, which the limits of his views permitted him to notice, are judicious; the ſpecies he deſcribes are, however, leſs numerous than might be expected, nor can we refrain adding, with due reſpect to the memory of that zealous and well informed naturaliſt, that all the ſhells deſcribed as ſpecies, are not defined in a clear and ſatisfactory manner. As a local catalogue we admit its general utility with this exception.

The above mentioned catalogue was printed in 1799, and in the Philoſophical Tranſactions for the ſame year, appeared Mr. Hatchet's “Experiments on Shell and Bone,” in which that accurate chemiſt relates the particulars of his diſcoveries reſulting from analyſis of the component parts of teſtaceous and cruſtaceous ſubſtances, in the firſt of which he detected the preſence of phoſphate of lime, and he found the other to conſiſt only of the carbonate of lime mixed with gelatinous matter. The publication of Donovan's “Natural Hiſtory of Britiſh Shells,” commenced early in 1799. This work was deſigned to include all the ſpecies hitherto diſcovered in Great Britain, ſyſtematically arranged in the Linnæan manner, with ſcientific and general obſervations on each. Five volumes have ſince appeared in a progreſſive courſe of publication, compriſing altogether 180 plates, with many coloured figures. The writer of this article does not feel at liberty to comment further on a work which he has himſelf ſubmitted with deference to public opinion. It is allowed by Dr. Maton and Mr. Rackett, in their review of teſtaceological writers, inſerted in the Linnæan Tranſactions, “that the author has given ſeveral new ſpecies, and that he has rectified many errors of preceding writers.”

The fifth or laſt volume of Mr. Dryander's “Bibliotheca Hiſt. Natur. Bankſiana,” was publiſhed in 1803. This is an account of the books on the ſubject of natural hiſtory, in the valuable library of Sir Joſeph Banks bart., and although only a catalogue, will be found to contain much general information. In the “Elenchus Sectionum,” we are preſented with a methodical arrangement of the principal teſtaceological ſubjects treated of by different writers, named in the other part of the catalogue; and which, in many reſpects, may prove more acceptable as a mode of reference than a catalogue conſiſting merely of the titles of the books and names of the authors.

A paper deſcribing the hinges of ſome Britiſh ſhells of the bivalve tribe, by Mr. W. Wood, is inſerted in the ſixth volume of the Linnæan Tranſactions. The attempt is ingenious, but on a very confined ſcale, and it preſuppoſes, without the ſlighteſt countenance of fact, that among the many writers who had previouſly noticed ſhells, or even written profeſſedly on them, no one had hitherto paid attention to their hinges. The paper is illuſtrated by ſix plates of outlines.

In 1803, the “Teſtacea Britannica” of Mr. G. Montagu, was publiſhed in two quarto volumes. The number of ſhells deſcribed in this work is conſiderable, as it comprehends an account of the microſcopic kinds, in addition to thoſe of a larger ſize. It is embelliſhed with ſixteen coloured plates.

“The Hiſtorical Account of Teſtaceological Writers,” to which, in the courſe of our foregoing obſervations, we have had frequent occaſion to advert, appeared in the ſixth volume of the Linnæan Tranſactions, publiſhed in 1804, and is the joint production of Dr. W. G. Maton, and the Rev. Thomas Rackett.

The “Tableau Methodique des Molluſques,” by Latreille, publiſhed in the twenty-fourth volume of the “Nouveau Dictionaire d'Hiſtoire Naturelle,” printed at Paris in 1804, affords us an arrangement of ſhells, founded on that of Lamarck, with ſome additions that may render it more applicable to general uſe.

The riſe, progreſs, and general traits of the hiſtory of this ſcience may be more readily collected, we apprehend, in the courſe of the foregoing review of the different works that have appeared on the ſubject, than from any other mode that might be deviſed; and, under this idea, we have adhered as nearly as poſſible to the chronological order of arrangement, this being the moſt likely to facilitate the purpoſe intended. From the peruſal of this, the reader will at once perceive which are the moſt conſiderable and valuable works on the ſubject, as well as obtain a general knowledge of a number of treatiſes, tracts, and memoirs, on particular articles connected with teſtaceology, which, being diſperſed through a variety of miſcellaneous and voluminous publications, might, without ſuch reference, eſcape attention. The leading features, or deſign, of the reſpective performances, are likewiſe detailed, and the embelliſhments which accompany them pointed out; and, in fact, every other particular deemed likely to aſſiſt the ſtudent in his choice of the beſt books in forming a teſtaceological library.

In reſuming this ſubject, as we propoſe under the article TESTACEOLOGY, we ſhall be prepared to offer ſome further, and more general remarks on this topic, and in particular to ſubmit our own ideas as to an enlarged and improved arrangement for the claſſification of teſtaceous bodies, founded on the leading principles of the beſt authors, with ſuch amendments as we conceive neceſſary. D.

Miſcellaneous Additions relative to Conchology.

The following inſtructions for collecting, cleaning, and preparing ſhells, may not be unacceptable.

The teſtaceous, like all other animals, have their particular reſorts; ſome inhabit only the deep parts of the ſea, and are what the old writers diſtinguiſhed by the name of pelagian ſhells; others are as conſtantly found in ſhallow water, in bays, or thoſe parts of the ſea which are contiguous to the entrance of rivers: it has alſo been obſerved, that many fine and rare ſhells are ſometimes found in the ſtraits between iſlands, and in ſhallows near the coaſt, of four or five fathom water. Some ſpecies alſo are found on rocky, and others on ſandy ſhores. The beſt ſhells are thoſe taken alive out of the ſea, from whence they may be obtained by means of a trawling-net, ſuch as the fiſhermen employ, if the depths are not too great; they are alſo brought up by the cable in weighing anchor, the log-line in ſounding, and various other means. Sometimes valuable marine ſhells are found ſticking to the bottoms of ſhips, or the ſides of rocks.

After a ſtorm, good ſhells may be picked up on the ſea beach or ſhore, as the violent agitation of the water in a tempeſt ſeparates them from their native beds, and often caſts them aſhore. But ſuch as have lain expoſed for ſome time to the heat of the ſun, or beaten by the waves, are of little value, as their colours will be found faded, and the ſhells worn and broken; thoſe only are worth ſelecting from the ſea-ſhore, which have the animal alive within, or which have been recently thrown up.

River ſhells are, in general, of an obſcure colour, and remarkably thin and brittle, inſomuch that ſome have imagined it a peculiar character, by means of which they may be diſtinguiſhed from the marine or terreſtrial kinds. This is not, however, an abſolute criterion, for many of the latter are as thin as the river ſhells, as we obſerve, for example, in the argonautæ, or paper nautili, ſome pinnæ, and many other ſea ſhells, and in numbers of the ſhells of the terreſtrial kind.

Terreſtrial, or land ſhells, though few in compariſon with the former, are oftentimes very beautiful, and not leſs eſteemed than the marine kinds. Thoſe are found moſt commonly crawling, like the ſnail tribe, on various ſorts of plants, and in warm countries eſpecially abound.

Many ſhells poſſeſs ſuch a ſmooth, and highly poliſhed ſurface, and are ſo beautiful in colour when they are fiſhed up, that art cannot improve their appearance, ſuch as for inſtance, the cypræa or cowry, and the voluta or volute, with many others. It is the commonly received opinion, that the animals, inhabiting all naturally poliſhed ſhells whatever, are capable of not only adding to the extent and growth of their ſhells, but that they are able, from time to time, as occaſion may require, to add a freſh poliſhed covering to the whole ſhell. Should this opinion be unfounded, they can at leaſt extend their organs to ſuch a length, as to clear away all impurities from their ſhells, as we ſeldom find any cowries with coral, or any extraneous bodies, adhering to any part of them.

Other ſhells are covered with an epidermis or membrane, intended no doubt by nature to defend them from accident, and aid their growth. The ſtructure of this epidermis varies very much, being in ſome laminated, in others fibrous or bruſh like, or pilous, and velvetty. The epidermis prevents the lepas, and other ſimilar ſhells, or marine worms, from fixing their habitations on them; it is worthy of remark, that moſt ſhells, with a ſcabrous ſurface, are covered with an epidermis. Many others, when taken out of the ſea, are ſlimy, and encruſted with filth, coralline, and other extraneous matter.

Immediately after gathering or collecting the ſhells, and thoſe eſpecially taken from the ſea, the firſt proceſs neceſſary, is to deſtroy and extract the animal inhabitant, without injuring the ſhell, and then to prepare the ſhell that it may not be damaged by the action of the marine ſalts, with which they are ſaturated. As ſhells are of a calcareous nature, all acids ſhould be as much avoided as poſſible, both in killing the animal, and preparing the ſhell; it is uſual to boil them in water for this purpoſe, but as boiling may injure the ſhells, it will be moſt adviſeable to dip them into ſcalding water, which will be ſufficient to kill the animal, after which, let them remain for two or three minutes to cool, and then put them into cold water, in which they may lie till they are taken out to be cleaned. The animal, by being killed in this manner, becomes condenſed, and ſomewhat ſolid, and may be picked out by any ſharp inſtrument.

Shells encruſted with extraneous matter ſhould be allowed to ſteep for ſome time in warm water, both for the ſake of moiſtening theſe ſubſtances, and to extract as much as poſſible the marine ſalts. They may be ſuffered to remain in water two or three minutes without any injury. After this bruſh them well, obſerving only that the bruſh muſt not be too hard. If that proves inſufficient to clean them, rub or bruſh them again with tripoli or emery, or put them into weak acid for the ſpace of a minute and then dip them into cold water; which proceſs may be repeated as often as will be neceſſary to remove the extraneous matter. Strong ſoap may alſo be uſed with a rag of woollen or linen cloth to rub them, or a ley of pearl-aſhes; and when cleaned finiſh them with a ſoft bruſh and fine emery.

Scientific collectors endeavour to preſerve one at leaſt of every ſhell with the epidermis on, to exhibit its natural appearance, together with the uncoated ſpecimens.

The epidermis may ſometimes be ſo thick that it will be neceſſary to take it off before the ſhell can be poliſhed. For this purpoſe pour a quantity of the ſpirits of nitre, or nitrous acid, into water, in the proportion of about one-ſixth or one-tenth part of the former; put this into a ſhallow baſon or ſaucer, and place the ſhell or ſhells therein, in ſuch a manner that the corroſive fluid may act only on the coat, without injuring the orifices or mouth, which in ſome caſes may be coated with bees-wax: change the ſituation of the ſhell every two or three minutes, that all the parts may be equally uncoated; wipe off the bubbles as occaſion may require with a feather, firſt dipped in water: when you perceive the enamel in any part free from the coat, take it out, and waſh off the aquafortis, and after this proceſs rub them with fine emery powder. If inſtead of a thick epidermis it is only a pellicle, it is ſufficient to ſteep it in hot water, and then pick it off; or ſteep the ſhell in vinegar till it peels off freely, or is corroded away. The epidermis of ſome ſhells is ſo coarſe and thick as to reſiſt the corroſive quality of acids diluted, or even of aqua-fortis; emery with ſtrong bruſhes is then ſubſtituted, or ſeal-ſkin, and pumice-ſtone, or the exterior coat may be ground off with a grind-ſtone, or files of various dimenſions. If the matter is too obſtinate to be cleared off by this means, pour ſome ſpirit of nitre into a cup or other veſſel, ſtop up every part of the ſhell that may be ſuſceptible of injury with ſoft wax, as carefully as poſſible, and put it into the liquor in the veſſel; remove it every minute into cold water, but obſerve never to ſhift it into the ſame water more than once, and waſh it every time before you return it into the corroſive liquor. If the ſhell is warted, irregular, or armed with points, examine it with a common magnifier, and if you perceive on the more prominent parts through the wax any appearance of the poliſhed ſurface, cover them with wax, and let the ſhell remain a few minutes longer in the ſpirit, take it out and waſh it again; after which, poliſh the ſhell with fine emery, and paſs a camel's-hair pencil with gum arabic over them to brighten the colours; the white of egg is ſometimes uſed, but it is very apt to turn yellow in time, though at firſt it appears glaring; and varniſh communicates a diſagreeable ſmell.

Some ſhells have naturally a ſlight politure; thoſe may be rubbed by the hand with chamois leather, which will give them a bright gloſſy appearance: avoid when poſſible the uſe of emery powder, as it is apt to detriment the beautiful workings on the ſhells; it cannot however be often left out of uſe.

It is deſirable as far as can be to point out the impoſitions which are often practiſed on thoſe who are not well acquainted with ſhells, and are therefore not aware that any individual ſhell may be made to aſſume a very different appearance by having the firſt or ſecond exterior coat of the ſhell removed by acids, or any other means. Thus, for example, we ſee that though the outer ſurface of the common cowry, or tide ſhell, is of a pale colour, with dark ſpots; when that is cleared off, it is of a fine violet colour: the ſea ears are clouded with brown, green, and white; but when that coat is rubbed away it appears of a beautiful pearl colour. Thus alſo the nautilus ſhell is externally of a pale brown or ochraceous hue, variegated with ſtreaks of cheſnut, but on the exterior coating being taken off, the whole ſhell will be found of that ſubſtance known by the familiar name of mother of pearl. The ſame circumſtance is obſerved of the true mother of pearl ſhell, the exterior coat of which is blackiſh; many of the trochi, or top ſhells, and an infinite variety of other ſhells of different genera are of the ſame deſcription. Among thoſe ſhells which alter their appearance moſt, we muſt not omit the volute, called by us the purple or violet tip, and by the French *onyx*; it has a brown epidermis which, being taken off, diſcovers the ground colour to be a dull yellow. When this is worked down to beneath the cruſt or ſurface, it is of a pure white, with the tip of a fine violet. We ſhall laſtly mention the common muſcle, the exterior coat of which is dull blueiſh black, that beneath purple, and the inner one white: ſometimes we have ſeen muſcles in the hands of dealers, and in ſcientific collections, of a fine purple colour, variegated with large diſtinct ſpots of white or brown, ſo dexterouſly managed as to have all the appearance of a ſhell in a natural ſtate, though in reality ſuch ſhells are the work of art, and no other than the common or edible muſcle. For this purpoſe thoſe of the largeſt ſize are uſually ſelected, which, being firſt uncoated down to the brighteſt purple ſurface, are afterwards fretted or rubbed with a file, in particular parts, till the white or inner coating is ſeen through the purple. The ſpots may be managed however with more certainty, by covering the whole ſurface with a thin coat of wax, then ſcraping off the wax in ſuch parts as it is deſigned ſhould exhibit ſpots, and laſtly ſuffering the ſhell to remain in ſpirit of ſalts diluted, or nitrous acid, till the outſide is corroded in thoſe parts down to the white or inner coat of the ſhell. After waſhing the ſhell, and clearing off the wax; the ſpots thus formed may be ſtained of any colour, according to the fancy of the operator. A preparation of the oxyd of iron, or mangane̔ſe, are moſt commonly employed, as theſe produce a brown colour of different tints, and form an indelible ſtain. The Dutch, who are great amateurs in conchology, paint ſhells with a variety of colours, and that ſo ingeniouſly, as to render it difficult to detect the impoſition. Neither are they leſs expert in joining broken ſhells, cementing and filling up holes pierced by marine worms, or fractures, and filling the mouths and tips in ſuch a manner as to entirely alter their appearance.

Foſſil ſhells ſhould be noticed here if any inſtructions were neceſſary for their preſervation; but theſe in general conſtitute the moſt durable part of a collection, being either chalky, caſts in flint or ſtone, or replacements of ſparry matter, with perhaps only ſome ſlight fragments of the ſhell adhering, and that very rarely. They are dug out of chalk-pits, lime-ſtone, or other ſtone-quarries, and coal-pits, &c. Vide "Donovan's Inſtructions for collecting and preſerving Subjects of Nat. Hiſt." from which the above particulars are chiefly extracted.

CONCHUCOS, in *Geography*, a juriſdiction of South America, in the vice-royalty of Peru, ſubject to the archbiſhop of Lima, which commences 40 leagues N.N.E. of Lima, and extends along the centre of the Cordilleras. Its air, therefore, is different according to the height of the ſituation of its ſeveral parts, the mildeſt of which produce all kinds of grains and fruits, and the others, where cold checks their fertility, afford paſture for all kinds of cattle. This juriſdiction abounds with looms: the principal occupation of the Indians being woollen manufactures of various kinds, which conſtitute the greateſt part of its commerce with other provinces.

CONCIATOR, in the *Glaſs Art*, is for the cryſtal glaſs what the founder is at the green glaſs-houſes. He is the perſon that weighs and proportions the ſalt on aſhes and ſand, and works them with a ſtrong fire, till they run into lumps, and become white; and if the metal be too hard, and conſequently brittle, he adds ſalt, or aſhes; and if too ſoft, ſand; ſtill mixing them to a fit temper, which is only known by the working.

CONCILIO.—*Querela eorum rege et* CONCILIO. See QUERELA.

CONCINNA, DANIEL, in *Biography*, an Italian Dominican, born in the Venetian territory about the year 1686. He was highly diſtinguiſhed for his pulpit talents, which attached to him numerous admirers in Italy, and even in Rome itſelf. As a writer he was eſteemed, on account of the ſupport which he gave to the inſtitutions of the Papal church. He was author of numerous publications in the Latin and Italian languages, on hiſtorical, moral, and critical ſubjects, among which are "Defenſio Concilii Tridentini, et Apoſt. Conſt. Eccle Rom. in cauſa Paupertatis Monaſticæ, &c." "Uſura Contractus trini Diſſertationis Hiſt. Theol. demonſtrata," &c. "De Spectaculis Theatralibus Chriſtiano cuiquam, tum Laico, tum Clerico, vetitis, &c." "Theologia Chriſtiana, dogmatico-moralis," in 12 vols. 4to. "Theological, Moral, and Critical Diſſertations, relative to the Logic of Probabilities, with Supplementary Obſervations." "A Defence of Revealed Religion, &c." He died at Venice in the year 1756. Nouv. Hiſt. Dict.

CONCINNOUS *Intervals*, in *Muſic*, are ſuch as are apt and uſeful in harmony, as the V., 4th, III., 3d, VI., 6th, IV. and 5th, in contradiſtinction to ſuch as are inconcinnous, as the intervals deficient or redundant by a comma. See COMMA-*Redundant*, *Fifth*, *Fourth*, &c.

CONCINO Concini, Marshal D'Ancre, in *Biography*, was a native of Tuſcany, and, with his wife, Leonora Galigai, accompanied Mary de Medicis, queen of Henry IV. into France, in 1660. He was made gentleman of the bed-chamber, governor of Normandy, and marſhal of France, in 1615. As he was raiſed by the influence which he attained over the mind of the queen, he held the reins of government during the minority of Louis XIII. and behaved in ſo haughty a manner to the young king, that he was induced to order his arreſt, and in caſe of reſiſtance, the perſon ſent on the buſineſs was commanded to kill him. The captain of the guard demanded his ſword as he was paſſing the drawbridge of the Louvre, and upon his refuſing to comply, he ſhot him dead, April 24, 1617. His body, after it had been buried, was taken up and given to the populace, who treated it with every indignity. His wife was afterwards condemned, by a decree of the parliament, to be hanged and burnt. Moreri.

CONCIOLO, an Italian painter, who flouriſhed in the commencement of the thirteenth century. Upon a picture at Subiaco, in the Eccleſiaſtical State, repreſenting the conſecration of a church, the artiſt has thus ſigned his name, Conxiolus pinxit, 1219. This is one amongſt the many proofs, with which the churches and converts of Italy abound, to ſhew that however low the ſtate of the arts in Europe, previous to Cimabue and Giotto, the intervention of Greek painters was by no means neceſſary to their eſtabliſhment. Lanzi. Storia Pittorica.

CONCIONATORES, in *Antiquity*, common-councilmen, freemen, called to the hall or aſſembly, as moſt worthy. Thus, "quodam tempore cum conveniſſent *concionatores* apud London, &c." Hiſt. Elien. apud Gale, c. 46.

CONCLAMATIO, a ſhout raiſed by thoſe preſent at burning the dead, before they ſet fire to the funeral pile. See Shout. The word was alſo applied to the ſignal given to the Roman ſoldiers to decamp, whence the expreſſion "conclamare vaſa;" and "conclamari arma" was a ſignal for battle. It was likewiſe uſed for a practice of calling to a perſon deceaſed three times by his name, and when no reply was returned, they thus expreſſed his deceaſe, "conclamatum eſt." Whence the ſame term was afterwards applied to the ceſſation of the Roman empire.

Conclamatio, among the Greeks, Romans, and ſeveral other nations, was a ſpontaneous cry or ſhout, which all the ſoldiers of an army made when they underſtood or heard the third ſignal for combat.

CONCLAVE, an aſſembly or meeting of all the cardinals that are at Rome, ſhut up for the election of a pope; whence it derives its name. See Cardinal.

The conclave had its riſe in the year 1270, and on this occaſion; Clement IV. being dead at Viterbo, in 1268, the cardinals were nearly three years, *viz.* from the 29th of November 1268, to the 1ſt of September 1271, without being able to agree on the election of a ſucceſſor; in effect, things were carried to ſuch paſs that they were upon the point of breaking up, without coming to any concluſion at all.

The magiſtrates of Viterbo, being appriſed of their deſign, by the advice of St. Bonaventure, then at Viterbo, ſhut the gates of their city, and locked up the cardinals in the pontifical palace adjoining to the cathedral, till they were brought to a better underſtanding.

Hence aroſe the cuſtom, which has ſince prevailed, of ſhutting up the cardinals in a ſingle palace, till they have elected the pope.

Such was the origin of the conclave, as related by Onuph. Panvinius, Ciaconius, and Papebroch.

Panvinius informs us, that John of Toledo, cardinal biſhop of Porto, ſeeing the cardinals daily praying the Holy Ghoſt to inſpire them with the ſpirit of concord and union, and yet diſcord continuing to reign among them, ſaid pleaſantly, "Let us uncover the room, elſe the Holy Ghoſt will never get at us." When this ſarcaſtic remark was reported to the magiſtrates of Viterbo, they immediately ordered the roof of the room in which the cardinals were aſſembled, to be taken off, hoping that this new inconvenience would oblige them to haſten the election; but their obſtinacy prevailed againſt all inconveniences, till the magiſtrates bethought themſelves of daily leſſening their ſubſiſtence; and this had the deſired effect. For being thus reduced to the alternative of ſtarving or agreeing, they left the election by compromiſe to ſix of their number; and then Gregory X. was elected.

Conclave is alſo uſed for the place wherein the election of the pope is performed; which is now at St. Peter's in the Vatican; though Gregory X. and Clement V. appointed it ſhould always be held in the place where the laſt pope ſhould die. But if he ſhould die in a borough or village, where the electors could not conveniently meet, the election was to take place in the epiſcopal city, or in the neareſt to it, if that city were under an interdict.

While the affair is in hand, if it be in winter, the walls and windows are all mured up, excepting only a ſingle pane, to give a little light; in ſummer the windows are not cloſed; but the great door of the hall is ſecured with four locks and four bolts; an aperture being, however, left, through which to ſupply the impriſoned prelates with victuals.

If the election takes place at Rome, the door of the conclave, and all the avenues to it are to be carefully guarded by the city-guards, by the Roman nobility, by the ambaſſadors of princes, and by the biſhops and conſervators of the city. If the election is to be made out of Rome, the ſame duty is incumbent upon the temporal lords and magiſtrates of the place; and it is a duty common to them all to ſee that nothing be carried into the conclave, or out of it, that has the leaſt tendency to retard or prevent a lawful election.

In the hall, which is very ample, there are cells or ſtalls erected for as many cardinals as are to be preſent at the election; the cells being only ſeparated by deal boards, and the room having no outlet, except to the privy.

The cells are marked with letters of the alphabet, and are diſtributed to the cardinals by lot: each cardinal puts his arms on the cell that falls to his ſhare.

No one ſhall be allowed to go into the common room or conclave, nor out of it, but in caſe of ſickneſs, or on ſome other urgent occaſion.

After the aſſembly has continued three days, they are only allowed one diſh for a meal; and after fifteen days more, only bread, wine, and water, though this rule is not very ſtrictly regarded.

Each cardinal is allowed two concláviſts, or ſervants to attend him, and to be ſhut up with him.

The election is begun ten days after the pope's deceaſe, and decided by a majority of two parts in three of the cardinals preſent, who vote by ballot; and if, upon ſcrutiny, no one of the candidates has two-thirds of the votes, the balloting muſt, after a ſtated interval, be repeated. And this continues to be reiterated if they ſhould remain ſhut up for years, till one of them attains the fore-mentioned ſuperiority. Cardinals who arrive before the election is finiſhed, are incloſed with the reſt.

Theſe regulations were principally eſtabliſhed by Gregory X. in 1274. But as this conſtitution of Gregory X.

was thought by the cardinals to be too rigorous, they prevailed upon Clement VI. in the year 1351, not long before his death, to mitigate it. Clement allowed them to have each two ſervants, clerks, or laymen; to have curtains round their beds, and one diſh of fleſh or fiſh at dinner, and another at ſupper, beſides bread, wine, fruit, and ſweetmeats, ſo long as they continued in the conclave.

Matthew Paris ſays, the word conclave anciently ſignified the pope's wardrobe.

It is a popular proverb in Italy, *chi entra papa, eſce cardinale;* he who enters pope, comes out cardinal; q. d. he who according to common report will be elected pope, ordinarily is not.

We have various accounts, both by proteſtant and popiſh writers, of the intrigues that have been practiſed in the conclave, during conteſted elections. What is ſaid to have paſſed upon the deceaſe of Alexander VII. is no tale invented by proteſtants, but related by grave Roman catholics, *viz.* that on the laſt day, cardinal Sforza, going into the conclave, aſked another cardinal, his intimate friend, what he thought would be the iſſue? He returned this frank anſwer: "Signior cardinal, if the French make the pope, he will be cardinal Farneſe; if the Spaniards, cardinal Roſpiglioſi; if he is made by the people of Rome, he will be cardinal Barberini; if the Holy Ghoſt appoints him, cardinal Odeſchalchi will be the man; if the devil has a hand in it, he muſt be your eminence, or myſelf." Upon this, Sforza replied with a laugh, "then Roſpiglioſi will be the man;" and he was accordingly choſen by the name of Clement IX. In the year 1724, upon the death of Innocent XIII, the following ſatirical diſtinction was made between the candidates for the papal throne:

"Il Cielo vuol Orſini
Il popolo Corſini
Le Donne Ottoboni
Il Diavolo Alberoni."

i.e. "Heaven is for Orſini,
The people for Corſini,
The ladies for Ottoboni,
The devil for Alberoni."

But Orſini was choſen by the name of Benedict XIII. Keyſler's Trav. vol. ii. p. 109.

CONCLUSION, in *Law*, is where a man by his own act upon record hath charged himſelf with a duty or other thing, or confeſſed any matter whereby he ſhall be concluded: as if a ſheriff returns that he hath taken the body upon a capias, and hath not the body in court, at the day of the return of the writ; by the return, the ſheriff is concluded from plea of eſcape, &c. Terms de Ley, 153, &c. In another ſenſe the word concluſion ſignifies the end of any plea, replication, &c. and a plea to the writ, is to conclude to the writ; a plea in bar, to conclude to the action, &c. Concluſion of plea in bar ſhall be, *et hoc paratus eſt verificare:*—of other pleas *et de hoc ponit ſe ſuper patriam.* Kitch. 219, 220. See PLEA.

CONCLUSION *of deeds*, mentions the execution and date of the deed, or the time of its being given or executed, either expreſsly, or by reference to ſome day and year before-mentioned. Not but a deed is good, although it mention no date, or hath a falſe date; or even if it hath an impoſſible date, as the 30th of February; provided the real day of its being dated or given, that is delivered, can be proved.

CONCLUSION, in *Logic*, the laſt part of an argument; or the conſequence drawn from ſomething either aſſumed or proved before.

The concluſion of an argument contains two parts: the conſequent, which is the matter of it; and the conſequence, which is its form, and which, of a ſimple abſolute propoſition, renders the concluſion relative to the premiſes whence it is drawn.

The queſtion and concluſion, ſay the ſchoolmen, are the ſame ideas, only conſidered in different views, or relations: in the queſtion they are conſidered as doubtful; in the concluſion as void of doubt.

CONCLUSION, in *Oratory*, conſiſts of two parts; the RECAPITULATION, or ENUMERATION, and the PASSIONS. See alſo PERORATION.

CONCLUSIONS *d'une procedure militaire*, Fr. See the article JUDGE *Advocate*.

CONCOBAR, in *Ancient Geography*, a town of Aſia, in Upper Media, towards the S.W. of Ecbatana.

CONCOCTION, in the *Animal Economy*, a term uſed by the older writers to denote the proceſs which the food undergoes in the ſtomach, and by which it is converted into chyme and chyle. This proceſs is now more uſually termed DIGESTION, which ſee.

CONCOCTION, in the *Pathology* of Hippocrates and Galen, and their numerous followers, was alſo employed to ſignify certain changes in the fluids in the courſe of acute diſeaſes, from a ſuppoſed analogy between the changes, and thoſe which the aliments undergo in the ſtomach during digeſtion. The proceſs of concoction may be particularly illuſtrated in the caſe of a common phlegmon, or boil; the progreſs of which is marked, according to Galen, by four diſtinct ſtages. The firſt, or *incipient* ſtage, when theſe fluids are beginning to collect, is conſidered as the ſtage of crude and unchanged humours: in the ſecond, or ſtage of *increaſe*, in conſequence of the proceſs of concoction, heat is diffuſed through the part, and the pain, tenſion, and tumour are increaſed: when the humours are completely concocted, and converted into *pus*, the ſtage of the phlegmon is ſaid to be *ſtationary*, or the diſeaſe to be in its vigour: and the fourth ſtage is that, in which the tenſion and tumour become leſs, and which is termed the *decline* of the ſwelling. A ſimilar progreſs is obſervable in almoſt all inflammatory diſeaſes. Thus in catarrh, affecting the mucous membrane of the noſe, the diſcharge in the commencement is thin and watery, and, in the language of the humoral pathology, *crude;* by degrees a thicker and more opake matter is diſcharged, which at length (becoming completely concocted), aſſumes a very thick and purulent appearance, which betokens the decline of the diſeaſe. Such alſo is the progreſs of change in the fluids expectorated in inflammations of the lungs and bronchiæ, diſcharged from the eyes in ophthalmia, &c. By an analogy ſomewhat remote, this doctrine was transferred to febrile complaints, where no local inflammation, or depoſitary of morbid concocting matter, exiſted. In an idiopathic fever, as ſynochus or typhus, the alvine excrements, the urine, and the diſcharge from the ſkin, were referred to, as evidence of the proceſs of concoction; and the varieties of the appearance of theſe diſcharges are deſcribed by Hippocrates, and his commentator Galen, as denoting the ſtates of crudity and of concoction, and hence as affording a prognoſis of the future progreſs and event of the diſeaſe. The alvine excrement is ſaid to be well concocted, when it is, as in health, ſoft and connected, and is diſcharged with the uſual regularity. When it is not in this ſtate, but liquid and watery, partly liquid, partly ſolid, &c. it is conſidered as not concocted, and therefore indicating the unhealthy condition of the bowels, through which it had paſſed. And thus, with reſpect to the urine, when it is extremely thin and limpid, it is ſaid to be crude; and when it is ſlightly tinged with yellow, it is conſidered as having undergone a ſmall degree of concoction, which is ſtill more complete, if it ſoon depoſits a moderate ſediment. But the ſigns of concoction in the urine were ſaid to be different in the young and the old, and different alſo in different diſeaſes. Thus in bilious and ſummer fevers, a light cloud ſuſpended in the urine was deemed the ſign of concoction; in inflammatory fevers, a white ſediment. See Galen, de Tot. Morbi. Tempor. et de Criſibus, lib. i.

CONCOLIN, in *Geography*, a town of France, in the department of the Iſere; 4½ leagues N.E. of Grenoble.

CONCOMITANT, in *Theology*, ſomething that accompanies, or goes along with, another.

Concomitant grace, is that which God affords us during the courſe of our actions to enable us to perform them; and as the Roman ſchoolmen ſay, to render them meritorious.

CONCOMITANT *Neceſſity*. See NECESSITY.

CONCORD, FORM OF, in *Eccleſiaſtical Hiſtory*, a ſtandard-book among the Lutherans, compoſed at Torgaw, in 1576, and thence called the Book of Torgaw, and reviewed at Berg, by ſix Lutheran doctors of Germany, the principal of whom was James Andreæ. This book contains in two parts, a ſyſtem of doctrine, the ſubſcription of which was a condition of communion, and a formal and very ſevere condemnation of all who differed from the compilers of it, particularly with reſpect to the majeſty and omnipreſence of Chriſt's body, and the real manducation of his fleſh and blood in the euchariſt. It was firſt impoſed on the Saxons by Auguſtus, and occaſioned great oppoſition and diſturbance, both among the Lutherans and Reformed.

Several of the moſt eminent churches of the Lutheran communion rejected it ſo firmly and reſolutely, that no arguments nor intreaties could engage them to admit it as a rule of faith, or even as a mean of inſtruction. Accordingly, it was rejected for various reaſons, by the churches of Heſſia, Pomerania, Nuremberg, Holſtein, Sileſia, Denmark, Brunſwick, and others. Among the Reformed, or Calviniſts, the Swiſs doctors, at the head of whom was Hoſpinian, the Belgic divines, thoſe of the Palatinate, together with the principalities of Anhalt and Bade, declared war againſt it. This form of concord, however, was patronized in a ſpecial manner by Julius, duke of Brunſwick, to whom, in a great meaſure, it owed its exiſtence; and who employed his authority and munificence in encouraging thoſe by whom it was compoſed, and in commanding all the eccleſiaſtics, within his dominions, to receive and ſubſcribe it as a rule of faith. But ſoon after it was publiſhed, this zealous prince changed his mind, ſuffered it to be publicly expoſed by the divines of his univerſity of Helmſtadt, and to be excluded from the number of creeds and confeſſions that were received by his ſubjects. Various means were uſed to obviate his objections; and particularly in the year 1583, a convocation of divines from Saxony, Brandenburg, Brunſwick, and the Palatinate, was held at Quedlinburg for this purpoſe. But Julius perſiſted in his oppoſition, and propoſed that the form of concord ſhould be examined, and its authority diſcuſſed by a general aſſembly or ſynod of the Lutheran church.

In the year 1614, John Sigiſmund, elector of Brandenburg, following the example of the landgrave of Heſſe, renounced Lutheraniſm, and, under certain reſtrictions, embraced the communion of the Reformed churches. This event occaſioned a diſpute, which was agitated with violence, and which occaſioned the form of concord to be ſuppreſſed in the territories of Brandenburg, and the ſubjects of that electorate to be prohibited, by a ſolemn edict, from ſtudying divinity in the academy of Wittemberg. Towards the cloſe of the 17th century, *viz.* in the year 1675, a new confeſſion of faith was drawn up by the Helvetic divines, under the denomination of the "form of concord or of agreement," which was alſo entitled the "Conſenſus;" but the introduction of it occaſioned conteſts and tumults in ſeveral places. It maintained, however, its credit and authority in the church of Geneva, until the year 1706, when, without being abrogated by any poſitive act, it fell into diſuſe. In ſeveral other parts of Swiſſerland, it was ſtill impoſed as a rule of faith, particularly in 1718, by the magiſtrates of Bern, who publiſhed an order, by which all profeſſors and paſtors, particularly thoſe of the univerſity and church of Lauſanne, who were ſuſpected of entertaining any erroneous opinions, were obliged to declare their aſſent to this formulary. Many paſtors and candidates for holy orders refuſed the aſſent that was demanded by the magiſtrates, and ſome of them were puniſhed for this refuſal. In conſequence of theſe warm conteſts and grievous complaints letters were addreſſed by George I., king of England, as alſo by the king of Pruſſia, in the year 1723, to the Swiſs cantons, in order to procure the abrogation of this form, or conſenſus, which was conſidered as an obſtacle to the union of the Reformed and Lutheran churches. Moſheim's Eccl. Hiſt. by Dr. Maclaine, vol. iv. v. vi.

CONCORD, in *Geography*, a flouriſhing poſt-town of America, in New Hampſhire, pleaſantly ſituated on the W. bank of Merrimack river, in Rockingham county, eight miles above Hookſet falls. The legiſlature has, of late, held its ſeſſions here; and on account of its central ſituation in the front of a thriving country, it will probably become the permanent ſeat of government. Much of the trade of the upper country centers here. This town is connected with Pembroke by a handſome bridge acroſs the Merrimack. Concord was incorporated in 1765, and has 1747 inhabitants. Its Indian name was "Penacook." It was granted by Maſſachuſetts, and called "Rumford." The compact part of the town contains about 170 houſes, a congregational church, and an academy, which was incorporated in 1790. It is 54 miles W.N.W. of Portſmouth, 58 S.W. of Dartmouth college, and 70 northward from Boſton. N. lat. 43° 12′. W. long. 71° 29′.

CONCORD, a town of America in the ſtate of Vermont and county of Eſſex, lying on Connecticut river, oppoſite to a part of the 15 mile falls.

CONCORD, a poſt-town of America, in the ſtate of Maſſachuſetts, being one of the moſt conſiderable towns in Middleſex county, ſituated on Concord river, in a healthy and pleaſant ſpot, nearly in the centre of the county, and 18 miles N.W. of Boſton, and 17 E. of Lancaſter. Its Indian name was Muſquetequid; and it owes its preſent name to the peaceable manner in which it was obtained from the natives. It was incorporated in 1635; being at that time the moſt diſtant ſettlement from the ſea-ſhore of New England. In 1791 this townſhip contained 225 dwelling houſes and 1590 inhabitants; and as a proof of the ſalubrity of its ſituation, 80 of the number were above 70 years old; and for 13 years before 1791, the average number of deaths was 17, one in four of whom was 70 years old or upwards. The public buildings are a congregational church, a ſpacious ſtone gaol, and a very handſome county court houſe. The river is croſſed by three bridges, of which one is 208 feet long and 18 feet wide, ſupported by 12 piers, and built after the manner of Charles river bridge. This town, during the revolution, was the ſeat of the provincial congreſs in 1774, and the ſpot where the firſt oppoſition was made to the Britiſh troops, on the 19th of April 1775. The grand court has been held here, when contagious diſeaſes have prevailed in the capital. N. lat. 42° 25′.

Concord, a ſmall river of Maſſachuſetts, formed of two branches, which unite near the centre of the town of Concord, whence it takes its courſe in a N.E. and N. direction through Bedford and Billerica, and empties itſelf into Merrimack river at Tewſkbury. This river is remarkable for the gentleneſs of its ſcarcely perceivable current. At low water mark it is from 100 to 200 feet wide, and from 3 to 12 feet deep. During floods it is nearly a mile in breadth: and when viewed from the town of Concord, exhibits a fine appearance.

Concord, a townſhip of Delaware county in the ſtate of Pennſylvania.

Concord, a ſettlement in Georgia, on the E. bank of the Miſſiſſippi, about a mile from the ſouth line of Tenneſſee, 108 miles N. from the mouth of Yazoo river, and 218 below the Ohio. N. lat. 33° 55′. W. long. 91° 25′.

Concord, in *Grammar*, that part of ſyntax, or conſtruction, whereby the words of a ſentence agree among themſelves, *i. e.* whereby nouns are put in the ſame caſe, number, gender, &c. and verbs in the ſame number and perſon, with nouns and pronouns.

The rules of concord are generally the ſame in all languages, as being of the nature of what is in uſe almoſt everywhere, for the better diſtinguiſhing of diſcourſe.

Thus, the diſtinction of the two numbers ſingular and plural obliges us to make the adjective agree with the ſubſtantive in number; that is, to put the one either in this or that number, according as the other is: for the ſubſtantive being the thing confuſedly, though directly, marked by the adjective; if the ſubſtantive word mark ſeveral, there are ſeveral ſubjects of the form marked by the adjective, and of conſequence this ſhould be in the plural; as *homines docti*, &c.

Again, the diſtinction of maſculine, and feminine, renders it neceſſary to put the ſubſtantive and adjective in the ſame degree.

And verbs ſhould have concord or agreement with nouns and pronouns in number and perſon.

If any thing occur apparently contrary to theſe rules, it is by a figure; *i. e.* ſomething is implied, or the ideas are conſidered more than the words themſelves. See Syntax.

Concord, *Order of*, in *Heraldry*, was inſtituted by Chriſtian-Erneſt, Margrave of Brandenburgh, on his return from Spain, in the year 1660, to diſtinguiſh the part he had taken in reſtoring peace and union to many European princes. The badge of the order is a gold croſs of eight points enamelled white, ſurmounted by an electoral crown; in the centre of the croſs a medal thereon, two olive branches paſſing ſaltierwiſe through two crowns: around the medal the motto *concordans*. On the reverſe the founder's cypher with the date of the inſtitution. This badge is worn pendent from an orange ribbon.

Concord, in *Law*, is the agreement between parties who intend the levying a fine of lands to one another, how and in what manner it ſhall paſs. This is uſually an acknowledgment from the deforciants (or thoſe who keep the other out of poſſeſſion) that the lands in queſtion are the right of the complainant. And from this acknowledgment or recognition of right, the party levying the fine is called the *cognizor*, and he to whom it is levied the *cognizee*. This acknowledgment muſt be made either openly in the court of common pleas, or before the lord chief-juſtice of that court; or elſe before one of the judges of that court; or two or more commiſſioners in the country, empowered by a ſpecial authority, called a writ of "dedimus poteſtatem;" by which judges and commiſſioners are bound by ſtatute 18 Edw. I. ſt. 4. to take care that the cognizors be of full age, ſound memory, and out of priſon. If there be any feme-covert among the cognizors, ſhe is privately examined whether ſhe does it willingly and freely, or by compulſion of her huſband.

Concord, is alſo an agreement made upon any treſpaſs committed (betwixt two, or more); and is divided into *concord executory*, and *concord executed*. Theſe concords or agreements are by way of ſatisfaction for the treſpaſs, &c.

Plowden obſerves, that the firſt binds not, being imperfect; but the latter is perfect, and binds the party.

Others are of opinion, that concords executory are perfect, and bind no leſs than thoſe executed.

Concord, in *Muſic*, denotes the relation of two ſounds which are always agreeable to the ear, whether heard in ſucceſſion or conſonance.

If two ſingle ſounds be in ſuch a relation, or have ſuch a difference of tone, as that, being ſounded together, they make a mixture, or compound ſound, which affects the ear with pleaſure; that relation is called *concord*: and whatever two ſounds make an agreeable compound in conſonance, thoſe ſame ſounds will always be pleaſing in ſucceſſion, or will follow each other agreeably.

The reverſe of concord is what we call *diſcord*; which is the general denomination of all the relations or differences of tone that have no pleaſing effect.

Concord and harmony are, in effect, the ſame thing; though cuſtom has applied them differently. As concord expreſſes the agreeable effect of two ſounds in conſonance: ſo harmony expreſſes the ſame ſort of agreement in a great number of ſounds in conſonance: add, that harmony always implies conſonance; but concord is ſometimes applied to ſucceſſion, though never but when the tones will make an agreeable conſonance; whence it is, that Dr. Holder, and ſome other writers, uſe the word conſonance for what we call concord.

Uniſonance, then, being the relation of equality between the tones of two ſounds, all the uniſons are concords, and in the firſt degree; but an interval being a difference of tone, or a relation of inequality between two ſounds, becomes a concord or diſcord, according to the circumſtances of the particular relation. Indeed ſome reſtrain concord to intervals, and make a difference of tone conſtitute the eſſential difference of concord and diſcord; but two uniſons cannot form an interval.

It is not eaſy to affirm the reaſon or foundation of concordance: the difference of tone, we have elſewhere obſerved, takes its riſe from the different velocity of the vibrations of the ſonorous body, *i. e.* of the velocity of thoſe vibrations in their recourſes; the more frequent their recourſes are, the more acute will be the tone, and *vice verſâ*.

But the eſſential difference between concord and diſcord lies deeper: there does not appear any natural aptitude in the two ſounds of a concord, to determine it to give us a pleaſing ſenſation, more than in the two ſounds of a diſcord: theſe different effects are merely arbitrary, and muſt be reſolved into the divine pleaſure.

We know by experience what proportions and relations of tone afford pleaſure, and what do not; and we know alſo how to expreſs the difference of tone by the proportion of numbers; we know what it is pleaſes us, though we do not know why: we know, *v. gr.* that the ratio of 1 : 2 conſtitutes concord, and 6 : 7 diſcord: but on what original grounds agreeable or diſagreeable ideas are connected with thoſe relations, and the proper influence of the one on the other, are above our reach.

By experience we know, that the following ratios of the lengths of ſtrings are all concord; *viz.* 2 : 1, 3 : 2, 4 : 3, 5 : 4, 6 : 5, 5 : 3, 8 : 5; that is, take any ſtring for a fundamental, which ſhall be repreſented by the number 1, and the following diviſions thereof will be all concord with the whole; *viz.* $\frac{1.2.3\text{[illegible]}3.5}{2.3.4.5.6.5.8}$.

So that the diſtinguiſhing character between concords and diſcords muſt be looked for in theſe numbers, expreſſing the intervals of ſound; not abſtractedly and in themſelves, but as expreſſing the number of vibrations. Now, uniſons are in the firſt degree of concord, or they have the moſt perfect likeneſs or agreement in tone; and therefore have ſomething in them acceſſory to that agreement which is found, leſs or more, in every concord: the nearer two ſounds come to an equality of tone, the ſlower are the beats, and the more agreement they have; therefore, it is not in the equality or inequality of the numbers that this agreement lies.

Further, if we conſider the number of vibrations made in any given time by two ſtrings of equal tone; on the principle laid down, they are equal: and therefore the vibrations of the two ſtrings coincide, or commence together as frequently as poſſible, *i. e.* they coincide at every vibration; in the frequency of which coincidence, or united mixture of the motions of the two ſtrings, and of the undulations of the air which they occaſion, it is, that the difference of concord and diſcord muſt be ſought. Now, the nearer the vibrations of two ſtrings approach to a coincidence as frequent as poſſible, the nearer they ſhould approach that condition, and conſequently the agreement of uniſons; which is confirmed by experience.

For if we take the natural ſeries 1, 2, 3, 4, 5, 6, and compare each number to the next, as expreſſing the number of vibrations in the ſame time of two ſtrings, whoſe lengths are reciprocally as thoſe numbers; the rule will be found exact, for 1 : 2 is beſt, then 2 : 3; after 6 the union is unſufferable; the coincidences being too rare: though there are other ratios that are agreeable, beſides thoſe found in that continued order, *viz.* 3 : 5, and 5 : 8, which, with the preceding five, are all the concording intervals within, or leſs than an octave, or 1 : 2; that is, whoſe acuteſt term is greater than half the fundamental.

On this principle, 3 : 5 will be preferable to 4 : 5; becauſe thoſe being equal in the number of vibrations of the acuter term, there is an advantage on the ſide of the fundamental in the ratio 3 : 5, where the coincidence is made at every third vibration of the fundamental, and every fifth of the acute term: ſo alſo the ratio 5 : 8 is leſs perfect than 5 : 6; becauſe, though the vibrations of each fundamental that go to one coincidence are equal; yet in the ratio 5 : 6, the coincidence is at every ſixth of the acute term, and only at every eighth in the other caſe.

Thus, we have a rule for judging of the preference of concords, from the coincidence of their vibrations: agreeable to which rule, they are diſpoſed into the order of the following table; to which the names of the concords in practice, the ratio of their vibrations, the lengths of the ſtrings, and the number of coincidences in the ſame, are expreſſed.

Ratios, or vibrations.				
	Grave Term.		Acute Term.	Coincid.
Uniſon	1	:	1	
Octave, 8ve	2	:	1	60
Fifth, 5th	3	:	2	30
Fourth, 4th	4	:	3	20
Sixth, gr.	5	:	3	20
Third, gr.	5	:	4	15
Third, leſſer	6	:	5	12
Sixth, leſſer	8	:	5	12
	Grave		Acute	
	Lengths.			

Though this order be ſettled by reaſon, yet it is confirmed by the ear. On this foundation, concords muſt ſtill be the more perfect, as they have the greateſt number of coincidences, with regard to the number of vibrations in both the ſtrings; and where the coincidences are equal, the preference will fall on that interval, whoſe acuteſt term has feweſt vibrations to each coincidence: which rule, however, is in ſome caſes contrary to experience; and yet it is the only rule hitherto diſcovered.

Indeed, Kircher, after father Merſenne, gives us another ſtandard for ſettling the comparative perfection of intervals with regard to the agreement of their extremes in tone: and it is this.

The perception of concordance, ſay they, is nothing but the comparing two or more different motions which in the ſame time affect the auditory nerve: now we cannot make a certain judgment of any conſonance, till the air is as often ſtruck in the ſame time by two ſtrings, as there are units in each member expreſſing the ratio of that concord; *v. gr.* we cannot perceive a fifth, till two vibrations of the one ſtring, and three of the other, are accompliſhed together; which ſtrings are in length as 3 to 2: the rule then is, that thoſe concords are the moſt ſimple and agreeable, which are generated in the leaſt time; and thoſe, on the contrary, the moſt compound and harſh, which are generated in the longeſt time.

For inſtance, let 1, 2, 3, be the lengths of 3 ſtrings, 1 : 2 is an octave; 2 : 3 a fifth; and 1 : 3 an octave and fifth compounded, or a twelfth. The vibrations of ſtrings being reciprocally as their lengths, the ſtring 2 will neceſſarily vibrate once, while the ſtring 1 vibrates twice, and then exiſts an octave; but the twelfth does not yet exiſt, becauſe the ſtring 3 has not vibrated once, nor the ſtring 1 thrice, which is neceſſary to form a twelfth.

Again, for generating a fifth, the ſtring 2 muſt vibrate thrice, and the ſtring 3 twice; in which time, the ſtring 1 will have vibrated 6 times; and thus the octave will be thrice produced, while the twelfth is only produced twice; the ſtring 2 uniting its vibrations ſooner with the ſtring 1, than with the ſtring 3; and they being ſooner conſonant than the ſtring 1 or 2 with that 3. Whence, that author obſerves, many of the myſteries of harmony, relating to the performance of harmonious intervals, and their ſucceſſion, are eaſily deduced.

But this rule, upon examining it by other inſtances, Mr. Malcolm has ſhewn defective, as it does not anſwer in all poſitions of the intervals with reſpect to each other; but a certain order, in which they are to be taken, being required: and there being no rule, with reſpect to the order, that will make this ſtandard anſwer to experience in every caſe: ſo that at laſt we are left to determine the degrees of concord by experience and the ear.

Not but that the degrees of concord depend much on the more or leſs frequent uniting the vibrations, and the ear's being more or leſs uniformly moved, as above; for that this mixture or union in motion is the true principle, or, at leaſt, the chief ingredient in concord, is very evident: but becauſe there ſeems to be ſomething farther in the proportion of the two motions neceſſary to be known, in order to fix a catholic rule for determining all the degrees of concord, agreeable to ſenſe and experience.

The reſult of the whole doctrine is ſummed up in this definition.—Concord is the reſult of a frequent union, or coincidence of the vibrations of two ſonorous bodies, and, by conſequence, of the undulating motions of the air, which, being cauſed by theſe vibrations, are like and proportionable to them; which coincidence, the more frequent it is, with regard to the number of vibrations of both bodies, performed in the ſame time, *cæteris paribus*, the more perfect is that concord: till the rarity of the coincidence, in reſpect of one or both the motions, produces diſcord. See ſome of the remarkable phenomena of ſounds accounted for from this theory, under the word Unison; ſee alſo Interval, &c.

Mr. Carre, in the Memoirs of the Royal Academy of Sciences, lays down a new general propoſition, to determine the proportion which cylinders are to have, in order to form the concords or conſonances of muſic. And it is this—that the ſolid cylinders, whoſe ſounds yield thoſe concords, are in a triplicate and inverſe ratio of that of the numbers which expreſs the ſame concords.

Suppoſe, *e. gr.* two cylinders, the diameters of whoſe baſes and lengths are as 3 to 2: it is evident their ſolidities will be in the ratio of 27 to 8, which is the triplicate ratio of 3 to 2: we ſay then, that the ſounds of thoſe two cylinders will produce a fifth, which is expreſſed by thoſe numbers; and that the biggeſt and longeſt will yield the grave ſound, and the ſmalleſt the acute one.—And the like of others.

Concords are divided into *ſimple*, or original, and *compound*.

A *ſimple*, or *original* concord, is that whoſe extremes are at a diſtance leſs than the ſum of any two other concords.

On the contrary, a *compound* concord is equal to two or more concords.

Other muſical writers ſtate the diviſion thus: an octave 1 : 2, and all the inferior concords above expreſſed, are all ſimple and original concords: and all greater than an octave, are called compound concords; as being compoſed of, and equal to the ſum of one or more octaves, and ſome ſingle concord leſs than an octave; and are uſually, in practice, denominated from that ſimple concord.

As to the compoſition and relations of the original concords, by applying to them the rules of the addition and ſubtraction of intervals, they will be divided into *ſimple* and *compound*, according to the firſt and more general notion; as in the following table.

Simple Concords	Compound Concords.			
5 : 6 a 3d leſſ.	4th	3dg. and 3dl.	8ve. compoſed of	5th 4th or 6th g. 3dl. or 3d. g. 3d. l. 4th.
4 : 5 a 3d gr.	6th l.	4th. 3dl.		
3 : 4 a 4th.	5th g.	4th. 3 g.		

The octave is not only the firſt concord in point of perfection, the agreement of whoſe extremes is greateſt and the neareſt to uniſon; inſomuch that, when ſounded together, it is impoſſible to perceive two different ſounds; but it is alſo the greateſt interval of the ſeven original concords; and, as ſuch, it contains all the leſſer, which derive their ſweetneſs from it, as they ariſe more or leſs directly out of it; and which decreaſe gradually, from the octave to the leſſer ſixth, which has but a ſmall degree of concord.

A remarkable circumſtance is the manner wherein theſe minor concords are found in the octave, which ſhews their mutual dependences.

For, by taking both an harmonical and arithmetical mean between the extremes of the octave, and then both an harmonical and arithmetical mean betwixt each extreme, and the moſt diſtant of the two means laſt found; viz. betwixt the leſſer extreme and the firſt arithmetical mean, and betwixt the greater extreme and the firſt harmonical mean; we have all the leſſer concords.

Thus, if betwixt 360 and 180, the extremes of octave, we take an arithmetical mean, it is 270; and an harmonical mean is 240: then, betwixt 360 the greateſt extreme, and 240 the harmonical mean, take an arithmetical mean, it is 300; and an harmonical mean is 288. Again, betwixt 180 the leſſer extreme of the octave, and 270 the firſt arithmetical mean, it is 225, and an harmonical one 216.

Thus, we have a ſeries of all the concords, both aſcending towards acuteneſs from a common fundamental 360; and deſcending towards gravity from a common acute term 180: which ſeries has this property, that taking the two extremes, and any other two at equal diſtances, the four will be in geometrical proportion.

The octave, by immediate diviſion, reſolves itſelf into a fourth and fifth; the fifth, again, by immediate diviſion, produces the two thirds; the two thirds are therefore found by diviſion; though not by immediate diviſion; and the ſame is true of the two ſixths. Thus do all the original concords ariſe out of the diviſion of the octave; the fifths and fourths immediately and directly, the thirds and ſixths mediately.

From the perfection of the octave ariſes this remarkable property, that it may be doubled, tripled, &c. and yet ſtill will preſerve a concord, *i. e.* the ſums of two or more octaves are concord; though the more compound will be gradually leſs agreeable: but it is not ſo with any other concord leſs than octave; the doubles, &c. of which are all diſcords.

Again, whatever ſound is concord to one extreme of the octave, is concord to the other alſo; and if we add any other ſimple concord to an octave, it agrees to both its extremes; to the neareſt extreme it is a ſimple concord, and to the fartheſt a compound one.

Another thing obſervable in this ſyſtem of concords is, that the greateſt number of vibrations of the fundamenta cannot exceed five; or that there is no concord where the fundamental makes more than five vibrations, to one coincidence with the acute term. It may be added, that this progreſs of the concords may be carried on to greater degrees of compoſition, even *in infinitum;* but ſtill the more compound, the leſs agreeable.

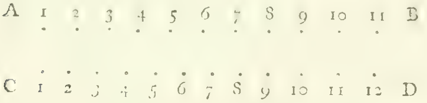
So a ſingle octave is better than a double one, and that than a triple one; and ſo of fifths, and other concords.

Three or four octaves form the extremes of all the intermediate ſounds; what will afford all the variety of pleaſure the harmony of ſounds is capable of affording, or at leaſt that we can receive; for we can hardly raiſe ſounds beyond that compaſs, either by voice or inſtrument, that ſhall not offend the ear.

The phenomena attending ſimultaneous ſounds have been conſidered by Euler, and treated of in ſo clear and perſpicuous

cuous a manner, that we cannot do better than uſe his own words in this place.

"On hearing a ſimple muſical ſound, our ear is ſtruck with a ſeries of pulſations equally diſtant from each other, the frequency and number of which, in a given ſpace of time, conſtitute the difference which ſubſiſts between low notes and high; ſo that, the ſmaller the number of vibrations or ſtrokes produced in a given time, ſay a ſecond, the lower we eſtimate that note; and the greater the number of ſuch vibrations, the higher is the note. The perception of a ſimple muſical ſound may, therefore, be compared to a ſeries of dots equidiſtant from each other, as . . . . If the intervals between theſe dots be greater or ſmaller, the ſound produced will be lower or higher. It cannot be doubted, that the perception of a ſimple ſound is ſomewhat ſimilar, or analogous, to the ſight of ſuch a ſeries of dots equidiſtant from each other: we are enabled thus to repreſent to the eye, what the ear perceives on hearing ſound. If the diſtances between the dots were not equal, or theſe dots were ſcattered about confuſedly, they would be a repreſentation of a confuſed noiſe, inconſiſtent with harmony. This being laid down, let us conſider what effect two ſounds, emitted at once, muſt produce on the ear. Firſt, it is evident, that if two ſounds are equal, or if each performs the ſame number of vibrations in the ſame time, the ear will be affected in the very ſame manner as by a ſingle note; and, in muſic, theſe two notes are ſaid to be in uniſon, which is the ſimpleſt union or combination of two ſounds: we mean by the term the blending of two or more ſounds heard at once. But if two ſounds differ in reſpect of low and high, we ſhall perceive a mixture of two ſeries of pulſations, in each of which the intervals are equal among themſelves, but greater in the one than in the other; the greater intervals correſponding to the lower note, and the ſmaller to the higher. This mixture, or this combination of two notes, may be repreſented to the eyes by two ſeries of dots, arranged on two lines, A B, and C D;



and in order to form a juſt idea of theſe two ſeries, we muſt have a clear perception of the order which ſubſiſts among them, or, in other words, of the relation between the intervals of the one line and of the other. Having numbered and marked the dots of each line, and placed N° 1 under N° 1; thoſe marked with the figure 2, will not exactly correſpond, and ſtill leſs thoſe marked 3; but we find N° 11 exactly over N° 12; from which we diſcover that the higher note makes twelve vibrations, and the other only 11. If we had not affixed the figures, the eye would hardly have perceived this order; it is the ſame with the ear, which would with much difficulty have traced it in the two notes, which are repreſented by two rows of dots. But in the following figure,

you diſcover at the firſt glance, that the upper line contains twice as many dots as the under, or that the intervals in the under are twice as great as thoſe of the upper. This is undoubtedly, next to uniſon, the ſimpleſt of all caſes, in which you can at once diſcover the order which ſubſiſts between theſe two ſeries of dots; and the ſame thing holds with reſpect to the two notes repreſented by theſe two lines of dots: the number of vibrations contained in the one, will be preciſely the double of the vibrations contained in the other, and the ear will eaſily perceive the pleaſing relation of theſe two ſounds; whereas, in the preceding caſe, it was extremely difficult, if not impoſſible, to diſcriminate. When the ear readily diſcovers the relation ſubſiſting between two notes, their combination is denominated conſonance; and if it be very difficult, or even impoſſible, to catch this relation, the combination is termed diſſonance. The ſimpleſt conſonance, then, is that in which the high note produces preciſely twice as many vibrations as the low note. This conſonance, in the language of muſic, is called octave; every one knows what it means; and two notes which differ preciſely in octave, harmonize ſo perfectly, and poſſeſs ſuch a complete reſemblance, that muſicians mark them by the ſame letters." Euler's Letters, vol. i.

Let the ſeries of equal parts contained in the parallel right lines 01, 02, 03, &c., *fig. a*, *Muſic-Plate*, repreſent the ſeries of equal times between the ſucceſſive pulſes of air that beat on the ear, when the ſingle ſounds 01, 02, 03, &c. are heard reſpectively; then, when any two of theſe ſounds are heard together, the combination of the two correſponding lines, will rightly repreſent the two ſeries of equal times, if the magnitude of the equal parts in one line be to the magnitude of thoſe in the other, in the ratio of the ſingle vibrations of the ſounds; or, the whole lines being ſuppoſed equal, if the number of aliquot parts in each be ſeverally the ſame, as the leaſt numbers of the vibrations of each ſound, made in the ſame time. And the points which divide the ſeparate lines, will ſubdivide the combined lines into ſmaller portions, as in *fig. b*, where $0\frac{2}{3}$ repreſents a third ſeries, or cycle of times, in which the pulſes of the ſounds 02 and 03 interchangeably ſucceed each other in beating upon the ear; in like manner $0\frac{3}{4}$ and $0\frac{3}{5}$ will repreſent the cycles reſpectively produced, by the union of the ſounds 03 and 04, in the firſt caſe, and 03 and 05 in the ſecond caſe. See CYCLE.

According to Dr. Smith, (Harmonics, p. 15.) ſuch a mixture of pulſes, ſucceeding one another in a given cycle of times, terminated at both ends by coincident pulſes, and ſufficiently repeated, is the phyſical cauſe that excites the ſenſation of a given conſonance or concord: eſpecially when conſidered as diſtinct from any other conſonance, whoſe ſingle vibrations having a different ratio from that of the former, will conſtitute a different cycle, and excite a different ſenſation. And although the abſolute times may be different, yet if the ratio is the ſame, the conſonances are ſimilar, and may be looked upon as the ſame in this reſpect, that their cycles have the ſame form; the times in both having the ſame order, and the ſame proportions. And that this form of the cycles ſerves to excite the ſenſation of a particular concord, is evident, from conſidering, that if the agreeable ſenſation of conſonances, according to the received principle in harmonics, be the reſult of the frequent coincidences of their pulſes, and conſequently be more or leſs agreeable, according as the coincidences are more or leſs frequent; all the conſonances in tempered ſyſtems, whoſe vibrations are incommenſurable, ought to be the greateſt diſcords in nature; it being impoſſible for their pulſes to coincide more than once in an infinite time. For as no two numbers, how large ſoever, can expreſs the ratio of ſuch vibrations, ſo no multiple of one vibration can ever be equal to any multiple of the other. And yet experience ſhews that ſuch conſonances are much more agreeable than perfect diſcords, whoſe pulſes coincide very often.

We may, indeed, ſays Dr. Smith (p. 99.) approach as near as we pleaſe; and certainly much nearer than the ſenſe can diſtinguiſh, towards the exact magnitude of an incommenſurable ratio, by the ratios of whole numbers; but as theſe will grow larger and larger without bounds, ſo will the time between the ſucceſſive coincidences, or the length of the approximating cycle of the pulſes; by which is meant the time of either of the incommenſurable vibrations, multiplied by the heterologous term of the approximating ratio. Let any man tell us then where we may ſtop, and which of thoſe cycles it is, whoſe repetition excites the determinate ſenſation of the conſonance.

The like difficulty occurs in approaching gradually even to a commenſurable ratio of the vibrations of any perfect conſonance. For, if either of its vibrations be pretty much altered at once, and then be made to approach by degrees to its former length, the terms of the ſeveral approximating ratios will grow larger and larger without bounds, and in regular order, except when ratios occur whoſe terms are reducible; and the cycles of their pulſes will accordingly be longer and longer, and their coincidences fewer without limit, thoſe interruptions excepted; and yet the conſonance will grow better and better by regular degrees, till it arrives at perfection, as is certain by experience. For inſtance, the ratios 30 to 21, 300 to 201, 3000 to 2001, &c. approach nearer and nearer to 3 to 2, and the Vths, whoſe vibrations are in thoſe ratios, grow more and more harmonious, though the cycles of their pulſes grow longer and longer to infinity.

It ſeems indiſputable, that coincident pulſes are not neceſſary to ſuch harmony as the ear judges to be perfect. For if any long period of imperfect uniſons, intercepted between two beats, be lengthened greatly and indeterminately, as in tuning an inſtrument, any given part of it, as long as any muſical note, will approach indefinitely near to perfect uniſons; certainly nearer than the ear can diſtinguiſh, as being often doubtful of their perfection. And yet throughout that part (ſuppoſed to be ſmall in compariſon to the whole period) the pulſes of one ſound divide the intervals of the pulſes of the other very nearly in a given ratio, of any determinate magnitude, between infinitely great and infinitely ſmall, in proportion to the diſtance of that part from the periodical point or point of coincidence. Nevertheleſs, the ear cannot diſtinguiſh any difference in the harmony of ſuch different parts, as is evident by often repeating the ſame conſonance, which can hardly begin conſtantly in the ſame place of the long period; and this argument applies to all other conſonances beſides uniſons.

Dr. Robiſon ſupports this train of argument, by a reference to the well known fact, that if two muſical inſtruments, as two organ pipes, tuned ſo exactly in uniſon that their pulſes may be ſuppoſed to begin and end at the ſame inſtants, making the moſt perfect coincidence of pulſes, be placed at a given diſtance from each other, and ſounded, the conſonance will be perfectly the ſame, in whatever part of the room or ſpace round the ſounding pipes the ear of an auditor may be placed; while, owing to the time taken up by ſound in travelling through a given ſpace, it is evident that the ſuppoſed coincidence of the pulſes in the ſounds cannot ſo affect or reach an ear unleſs it be placed exactly at equal diſtances from each of the ſounds; whereas, by placing himſelf exactly in the middle of the right line joining two uniſon ſounds, and gradually approaching one of the ſounds, every poſſible diſlocation or deviation of the pulſes from coincidence will prevail, in their action upon one of the ears of an obſerver, while in moſt caſes the other ear will be very differently affected upon, owing to its relative diſtances from the ſounding bodies being different. And hence, as Dr. Robiſon concludes, "a muſical ſound is the ſenſation of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious ſound is the ſenſation produced by another definite form of the agitation. This is the compoſition of two other agitations; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the ſenſation, making it pleaſant or unpleaſant," or in other words, a concord or a diſcord.

On the ſuppoſition that nature has appointed no certain limits between concords and diſcords, Dr. Smith (Harmon. p. 15.) inquires into the order of ſimplicity of the conſonances between different ſounds, perfectly adjuſted according to their ratios, on the principle, that one conſonance may be conſidered as more or leſs ſimple than another, according as the cycle of times belonging to it is more or leſs ſimple than the cycle belonging to the other, or, as the ſum of the leaſt terms expreſſing the ratio of the ſingle vibrations is ſmaller than the like ſum in the other conſonance; and that, when ſeveral ſuch ſums are the ſame, theſe conſonances are ſimpler in the ſame order as the leſſer terms of their ratios are ſmaller; and he diſpoſes the conſonances in a table, differing little, except in arrangement of the columns, from the following:

Order of the Simplicity.	Ratios of the vibrations.	Concords.	Order of the Simplicity.	Ratios of the vibrations.	Concords.
1	1 : 1	Uniſon.	16	1 : 16	XXIX
2	1 : 2	VIII	$16\frac{1}{8}$	2 : 15	
3	1 : 3	XII	$16\frac{1}{5}$	5 : 12	10th
4	1 : 4	XV	$16\frac{7}{8}$	8 : 9	
$4\frac{1}{2}$	2 : 3	V	17	1 : 17 *

15	1 : 15				

The firſt and ſecond columns of this table can ſcarcely need any explanation; the third contains the concords, major and minor, expreſſed as in the ſecond column of the general table of concords, which follows in this article: the blanks in this column denote the diſcords, ſuch as are marked with a * being compoſed of primes larger than 5, as 7, 11, 13, &c. and have no exiſtence in muſic, except in the falſe notes of the TRUMPET, HORN, &c.; ſee thoſe articles: the others, or their octaves, will be found in the table of DISCORDS; ſee that article.

On the other hand, Dr. Robiſon and other writers have maintained, and we think juſtly, that nature has not left the concords without other diſtinctions than the capricious and uncertain preference given to them by muſicians, but in addition to the almoſt univerſal delight which concords afford to every deſcription of auditors, that the phenomena of ſlow and audible beats, accompanying each concord, when ſlightly tempered either in exceſs or defect, ſufficiently diſtinguiſh ſuch from all other muſical intervals, compriſed properly under the denomination of diſcords, or imperfect concords; and we cannot but agree with Dr. R. in thinking, that the ſtudy of the principles of harmonics would be greatly facilitated by conſidering the concords as the elements or fundamental intervals of melody fixed by nature, and that we ſhould proceed to ſupply the other ſteps wanting in the ſcale, from their differences or combinations, rather than by aſſuming the tones and hemitones (which are diſcords that the moſt refined ear cannot accurately appreciate) to be the elements for compoſing the practical intervals of muſic; which it is not meant to contend, that they cannot accurately do in theory, but that concords of the truth or exact magnitude of which ordinary ears can at once judge with ſufficient exactneſs (while the curious can adjuſt ſuch in practice, by help of the beats, to any deſired degree of accuracy) are better adapted to the purpoſes of harmonical computations and reaſonings, and will admit of more direct and perhaps alſo of ſome new applications in practice.

For illuſtrating this ſubject, we beg to be allowed to mention an experiment by Dr. Robiſon, made with a wheel monochord, perhaps improperly ſo named, becauſe it had two ſtrings, which, by means of a reſined revolving wheel, could be made to yield clear and even ſounds for any required ſpace of time: one of the ſtrings giving conſtantly the ſame ſound, while the length of the other, after being accurately tuned in uniſon therewith, admitted of being ſhortened in any required degree, without altering its tone.

Beginning with the uniſon (but which was not exactly the order in the Doctor's experiment), the moveable bridge, which determined the length of the variable ſtring, was ſlowly and gradually moved forwards; at firſt a very ſlow, and by degrees a quicker, beating of the imperfect uniſon was heard, which increaſed in rapidity until the beats could no longer be counted, and at length they became a violent rattling flutter, which degenerated into a diſagreeable jar. Still advancing the bridge, vile diſcordant noiſes reſulted from the ſound of the two ſtrings, until the variable ſtring had been ſhortened nearly $\frac{1}{10}$, or when a little more than $\frac{9}{10}$ of the ſtring continued to ſound; when a very rapid angry flutter commenced, that became rather leſs rapid and offenſive as the point $\frac{9}{10}$ was approached, and again increaſed after that, until the diſcordant jar prevailed again; and this continued, until $\frac{8}{9}$ of the ſtring was approached, when a ſimilar flutter commenced, decreaſed, and again increaſed as this point was paſſed by the bridge; the jar beginning again, and accompanying the motion of the bridge, until it almoſt arrived at $\frac{5}{6}$ths of the ſtring's length, when a flutter and rapid beat commenced, decreaſing in frequency, until at $\frac{5}{6}$, or when the minor third (3^{d}) was ſounded, they ceaſed entirely, and the reſult was a concord rather agreeable than otherwiſe, but ſtrongly marked by a mournful melancholy in the expreſſion; which, being ſufficiently noticed, the bridge was again advanced, and produced the ſame beating, ſlow at firſt, then quicker, and at length fluttering, until the like grating diſſonance ſucceeded as before. This continued, until near the point marked $\frac{4}{5}$, when the beatings again commenced, having a peeviſh fretful expreſſion as they decreaſed in quickneſs, owing to the advance of the bridge, to the point of the major third (III), when the beats ceaſed, and the peculiarly enlivening and gay character of this concord was experienced by the hearers, who noticed an angry and waſpiſh expreſſion to accompany the ſucceeding beats as the ſtring ſhortened, but which gave place gradually to the ſame flutter and jar as before.

When little more than $\frac{3}{4}$ths of the ſtring's length continued to ſound, the flutterings and rapid beats were again heard, and the latter decreaſed and ceaſed entirely, at the point marking the fourth (4^{th}) which was noticed as a ſoft and agreeable concord. To this firſt ſlow, and then rapid, beats ſucceeded, and rapid flutterings, and a jarring noiſe. Near $\frac{32}{45}$ths of the ſtring the fluttering commenced again, and decreaſed until about ſix of them could be counted in a ſecond of time as the falſe IV was paſſed, after which they increaſed again in rapidity as the bridge advanced, and an indiſtinct and jarring noiſe ſucceeded, which ſoon again became a flutter that decreaſed until at $\frac{45}{64}$ths of the ſtring about eight of theſe angry flutters could be counted in a ſecond, correſponding to the falſe fifth, after which they increaſed in rapidity, and the jarring noiſe was again heard.

The bridge being progreſſively moved, the flutterings began, beats ſucceeded, and paſſed into a gentle and not unpleaſant undulation which ceaſed entirely at $\frac{2}{3}$ds of the ſtring, when the fifth (V) with the cheering ſweetneſs which characterizes it, was heard in the accordance of the two ſounds, neither of which could be ſeparately diſtinguiſhed: after which the ſlow and rapid beats, and fluttering, and jar ſucceeded as before. Some time before the bridge reached the mark for $\frac{5}{8}$ths of the ſtring the flutter and beats began again, and at that point the minor ſixth (6^{th}) a conſonance in a ſlight degree pleaſant was heard of a mournful character, without any beatings, but which were heard to recommence and increaſe as the bridge advanced; and the jarring diſſonance contiuued, until little more than $\frac{3}{5}$ths of the variable ſtring was left ſounding, when flutters and beats ſucceeded, and ſuch ceaſed when the true major ſixth (VI) was heard, the character of which it was found difficult to expreſs, otherwiſe than as being greatly inferior to the V in ſweetneſs, and to the III in gaiety, but poſſeſſing in a lower degree both of theſe qualities: ſhifting the bridge forwards, beats, flutters, and diſcordant noiſes ſucceeded, attended with two perceptible changes to flutters, in its progreſs towards the $\frac{1}{2}$ of the ſtring; which was not reached without the violent flutters, rapid and ſlower beats, ſo often before deſcribed; but when the beatings ceaſed the true octave (VIII) was heard, the treble note being with difficulty diſtinguiſhed from the baſs or fundamental afforded by the other ſtring, and not at all ſo if the notes were duly apportioned in loudneſs. After this, if the bridge was ſtill further advanced, beats, flutters, &c. ſucceeded as before, anſwering to the octaves of the ſounds already deſcribed, as the bridge advanced to make half of the lengths of the former ſtrings, reſpectively.

The doctor concludes his account of this very intereſting experiment by remarking, that he has perhaps been raſh in affixing certain moral or ſentimental characters to certain concords; becauſe he had ſeen inſtances of perſons who gave them different denominations, but theſe were never contradictory to his, but always expreſſed ſome ſentiment allied to thoſe above aſſigned. A perſon capable of a little diſcriminating reflection was never met with by the doctor, who did not acknowledge a manifeſt ſentimental diſtinction among the different concords, which could not be confounded. Speaking in another place on this ſubject, the doctor remarks, that he had made numberleſs trials of the different concords with perſons altogether ignorant of muſic; none of all thus examined had much pleaſure from an octave; all without exception, were delighted with a fifth, and with a major third, and many of them preferred the latter. All of them agreed in calling the pleaſure from the fifth a ſweetneſs, and that from the major third a cheerfulneſs or ſmartneſs, or by names of ſimilar import. The greater part preferred even the major ſixth to the fourth, and ſome felt no pleaſure at all from the fourth. Few had much pleaſure from the minor third or minor ſixth. Care was in the above inſtances taken, to ſound theſe concords without any preparation, merely as ſounds, not as making part of any muſical paſſage, circumſtances which have great effect on the mind. When the minor third and ſixth were heard as making part of the minor mode, all were delighted with them, and called them ſweet and mournful. In like manner the chord $^{6}_{4}$ never failed to give pleaſure. Dr. Smith (Harmonics, p. 21.) ſeemed to think that the concords within the octave would be found to affect the ear with ſmoother and pleaſanter ſenſations in the following order: *viz.* VIII, V, 4th, VI, III, 3^{d}, 6th, the laſt being the leaſt harmonious; but this concluſion he ſeemed to have formed from the numerical ſimplicity of their ratios as expreſſed in his Table above, rather than from a ſeries of experiments on their effects: but it is plain that this cannot expreſs the order of harmoniouſneſs, becauſe four diſcords will be found to intervene among the ſeven concords above, two of which alſo include the primes 7 and 11, which excludes them from our ſcale of muſic.

It will appear from the above, that each of the ſeven concords has a natural foundation and place in the ſcale of melody, but perhaps they will not all be found equally fit to be conſidered as elements in compoſing the ſcale. Reſpecting which, it may be right here to obſerve, that no general and ſtrictly accurate method of notation, for compoſing or ſhewing the relations of muſical intervals, can have leſs than three terms (for logarithms are only an approximation to their ratios, depending on the number of places of figures uſed) whether theſe are the muſical integers, 2, 3, and 5; the intervals T, *t*, and H; Σ, *f*, and *m*, or any other (Phil. Mag. xxvii. 195, and xxviii. 140). The comparative perfection of the harmony of the VIII, V, and 4th, the facility with which they can be tuned by the ear, and the ſimplicity of their ratios $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{3}{4}$, might ſeem to point them out as the moſt eligible, for concordant elements of the ſcale, but conſiderable experience in theſe kinds of calculations and inquiries has led us to prefer the three ſmalleſt concords, or 4th, III, and 3^{d} for this purpoſe; (ſee *Common* CHORD,) becauſe ſubſtraction of the ratios is thereby moſt avoided, at the ſame time that the larger concords can by inſpection be formed, out of theſe, in moſt inſtances. The following Table has been calculated and arranged with conſiderable care and trouble, and it will, we hope, prove uſeful to our muſical readers in ſaving much of their time when purſuing theſe curious and uſeful ſpeculations.

A TABLE of the Relations which the ſeveral Concords bear to the Key-Note, within the Compaſs of Seven Octaves.

	Intervals, Major and Mior.	Letters.	Ratios.	Common Logarithms.	Ratio in their Component Primes.	Tuneable Intervals.				

The titles of the columns are placed at the bottom of the foregoing Table, becauſe it is intended to be read from the bottom upwards, agreeably to the practice of muſicians, who read their notes upwards. Column 1 contains the number of finger-key intervals or half-notes: it will be found of uſe, in rough calculations reſpecting muſical intervals; thus, ſuppoſe a VI were to be added to a 6th, and it was required to know on what note the ſum would fall, we have 9 + 8 = 17, which anſwers in the Table to the 11th, and which happens to be exactly their ſum, as is evident by comparing column 7: ſuppoſe again, that it was required to know the interval anſwering to three IIIds, we have in this caſe 4 × 3 = 12; this in the Table anſwers to the VIII, but it is evident from col. 7, that this is only an approximate value, becauſe this is 4 + III + 3 inſtead of 3 III, the difference being an enharmonic dieſis, or the Tierce wolf of earl Stanhope.

Column 2 contains the marks of the intervals, the major intervals being denominated by Roman, and the minor intervals by Arabic characters, or numbers. Column 3 ſhews the notes of the gamut, diſtinguiſhing the ſeven different octaves, the firſt or loweſt by Roman capitals, the next by Italic ſmall letters, the third by theſe accented, the fourth by the ſame double accented, the fifth by three accents, and the ſixth and ſeventh octaves by ſmall figures or indices, to expreſs the number of accents.

Column 4 contains the ratios of the ſeveral notes, in their loweſt terms. Column 5 contains the common or Briggs's logarimths to eight places of figures, the laſt being ſeparated by a comma, in order to agree with the common tables, which have only ſeven places: whenever this number only is wanted, the ſeventh figure muſt be increaſed an unit, in every caſe where the eighth figure in the table exceeds 5.

Column 6 ſhews the ratios, expreſſed in their component primes, for the convenience of decompoſing the ſame into tuneable intervals, as explained in our article Comma; thus, the ſecond fraction, or $\frac{3}{2.2.2.2.2.2.5}$ may be divided or expreſſed by $\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{2}$, $\frac{1}{2}$, $\frac{3}{5}$ which ſhews it to be equivalent to 6 VIII + VI, as in column 7. The fraction anſwering to the 6th, or $\frac{5}{2.2.2}$ may be thus ſtated, *viz.* $\frac{1}{2}$, $\frac{5}{4}$, or VIII – III, the laſt term being negative, becauſe the ratio or fraction expreſſing it is found reverſed.

Column 7 contains ſeveral different values of each interval in col. 2, all expreſſed in tuneable intervals, or concords: the firſt, in each caſe, is expreſſed in the concordant elements, or ſmalleſt concords 4, III and 3d; the next expreſſion in each line has one or more VIIIths in its compoſition; we have next given thoſe tuneable intervals, which are found to expreſs each interval by two terms only; and have then added two others, (being all that our room would admit) of the various expreſſions in tuneable intervals, which can be had for any concord in col. 2, eſpecially if negative ſigns are admitted, as we have done in the loweſt octave of our table. Matter for curious reflection will preſent itſelf to the muſical ſtudent, who attentively conſiders the laſt column of our table, ſuch as; 1ſt, that the octave is the only concord which admits of being added to itſelf, without producing a diſcord; 2dly, that the complement of every concord to an octave (or to 2, 3, 4, &c. octaves,) is a concord; 3dly, that all the ſimple combinations by one, by two, or by three, of our concordant elements 4th, III and 3d, produce concords; 4thly, after theſe ſimple combinations are made, no farther ones can be made, except the addition of an equal number of each of the concordant elements (as 4 + III + 3, ²4 + 2 III + ²3, &c.) without producing diſcords; &c. If the difference between any two concords be wanted, as between the XVII and the X, ſuch is readily obtained from column 7th thus; ²4 + 3 III + ²3 – 4 – 2 III – 3 is equal to 4 + III + 3, or the octave. The ſum alſo of any concords, as a VI and 6th, is thus obtained; 4 + III + 4 + 3, or ²4 + III + 3, which anſwers to the 11th, as before obſerved, when explaining the uſes of column 1.

It may be of uſe here to mention, that the differences between each adjoining concord, in each ſeveral octave in column 7, will be found to be 3d, III – 3 (or the minor ſemitone, $\frac{24}{26}$), 4 – III (or the major ſemitone $\frac{15}{16}$) III + 3 – 4, or V – 4 (or the major ſemitone $\frac{8}{9}$), 4 – III, III – 3, and 3d; and this, whether we begin at the top or at the bottom of the octave. which ſhews that nature has diſtributed theſe ſix concords, in a ſurpriſingly uniform manner, between the uniſon and the octave. The intervals which will, in addition to thoſe above, be found by deducting every concord within the octave from each other, are, 4 – 3 (or the minor tone, $\frac{9}{10}$) and 4 + III – 3, or VI – 3 (or the comma-deficient tritone or ſharp fourth $\frac{18}{25}$).

It has been remarked by Mr. Holder, that the number 6 combined with itſelf, or with every leſs integer, produces in every inſtance a concord, thus $\frac{6}{6}$, $\frac{6}{5}$, $\frac{6}{4}$, $\frac{6}{3}$, $\frac{6}{2}$, and $\frac{6}{1}$, expreſs the uniſon, 3d, V, VIII, XII and XIX.

Concord, or *Concordia*, in *Mythology*, was perſonified by the Romans, and worſhipped as a deity under this appellation. Concord is commonly repreſented on coins as a graceful female, holding a cup in her right hand, and in her left ſometimes a ſceptre, and at other times a cornucopia, to intimate that plenty is the reſult of unanimity and friendſhip. Her ſymbols were two hands joined, as is ſeen on a coin of Aurelius Verus, and another of Nero; alſo two ſerpents twiſting round a caduceus. Mr. Spence obſerves, that concord is ſometimes repreſented with two cornucopias in one of her hands, a thing, ſays he, which I do not remember to have ſeen in any figure but her's, and as agreement often doubles the advantages we receive from the world, they ſeem to be given her with more propriety than perhaps they could be to any other.

Concord, *Temple of*, a building erected in Rome, at the expence of the public, upon an eminence at the foot of the capitol; ſo that it was ſeen from the forum, and the places where the aſſemblies were held and juſtice was adminiſtered. This temple was built in purſuance of a vow of Camillus to this purpoſe. See the article Camillus.

Concord had ſeveral other magnificent temples, beſides this and another erected by Tiberius, at the requeſt of his mother Livia. In one of theſe temples were depoſited the rich ſpoils of the temple of Jeruſalem.

CONCORDANCE, a dictionary or index to the bible, wherein all the leading words, uſed in the courſe of the inſpired writings, are ranged alphabetically; and the various places where they occur referred to; to aſſiſt in finding out paſſages, and comparing the ſeveral ſignifications of the ſame word.

Cardinal Hugo de St. Charo is ſaid to have employed five hundred monks at the ſame time in compiling a Latin concordance: beſides which, we have ſeveral other concordances in the ſame language; one, in particular, called the concordance of England, compiled by J. Darlington, of the order of Prædicants; another more accurate one, by the Jeſuit de Zamora.

R. Mordecai Nathan has furniſhed us with a Hebrew concordance, firſt printed at Venice in 1523, containing all the Hebrew roots branched into their various ſignifications, and under each ſignification all the places in ſcripture wherein it occurs: but the beſt and moſt uſeful Hebrew concordance is that of Buxtorf, printed at Baſil in 1632.

Dr. Taylor publiſhed, in 1754, a Hebrew concordance in two volumes folio, adapted to the Engliſh Bible, and diſpoſed after the manner of Buxtorf. See the preface of this work.

The Greek concordances are only for the New Teſtament: indeed we have one of Conr. Kircher's on the Old; but this is rather a concordantial dictionary than a concordance; containing all the Hebrew words in an alphabetical order; and underneath, all the interpretations or ſenſes the LXX. give them; and in each interpretation, all the places where they occur in that verſion.

In 1718, Trommius publiſhed his Greek concordance for the Septuagint at Amſterdam, in two volumes folio; and Schmidius, improving on a ſimilar work of H. Stephens has given an excellent Greek concordance for the New Teſtament, the beſt edition of which is that of Leipſic, an. 1717.

Calaſius, an Italian Cordelier, has given us concordances of the Hebrew, Latin, and Greek, in two columns: the firſt, which is Hebrew, is that of R. Mordecai Nathan, word for word, and according to the order of the books and chapters: in the other column is a Latin interpretation of each paſſage of Scripture quoted by R. Mordecai; this interpretation is Calaſius's own; but in the margin he adds that of the LXX. and the Vulgate, when different from his. The work is in four volumes folio, printed at Rome in 1621.

Of all the helps towards underſtanding the Hebrew Scriptures, ſays Dr. Geddes (Proſpectus, p. 71.) a good concordance is undoubtedly the moſt uſeful. But we yet want a good concordance; and the man who ſhould devote five or ſix years to the compiling of one from Buxtorf, Calaſio, Noldius, Taylor, Kircher, Montfaucon, and Trommius, would do a ſingular ſervice to biblical ſtudies. Buxtorf's method of arrangement, with very little improvement, ſhould be ſtrictly followed; the errors of orthography rectified from the authority of manuſcripts and other ſources of emendation; and the various acceptations of the ſame word in the ancient verſions exactly noted and methodically diſtinguiſhed. Such a work would be worth all the commentaries that have ever been made.

We have ſeveral very copious concordances in Engliſh; as Newman's, &c. but the laſt and beſt eſteemed is that in 4to. by Alex. Cruden.

CONCORDANT *Elements*, in *Muſic*, are the fourth (4^{th}) the major third (III) and the minor third (3^{rd}); ſee Concord. Dr. Smith conſiders the major tone (τ) the minor tone (t) and the hemitone (*s*) as elements; Harmonics, p. 13.

Concordant *Verſes*, ſuch as have ſeveral words in common; but which, by the addition of other words, convey an oppoſite, at leaſt, a different meaning. Such are theſe.

$$\textit{Et}\left\{\begin{matrix}\textit{Canis}\\ \textit{Lupus}\end{matrix}\right\}\textit{in ſilva}\left\{\begin{matrix}\textit{venatur}\\ \textit{nutritur}\end{matrix}\right\}\textit{\& omnia}\left\{\begin{matrix}\textit{ſervat.}\\ \textit{vaſtat.}\end{matrix}\right.$$

CONCORDAT, in the *Canon Law*, denotes a covenant, or agreement concerning ſome beneficiary matter, as a reſignation, permutation, promotion, or the like.

The council of Trent, ſeſſ. vi. *de reform.* cap. 4. ſpeaking of concordats made without the authority and approbation of the pope, calls them *concordias quæ tantum ſuos obligant auctores, non ſucceſſores*. And the congregation of cardinals, who have explained this decree, declares alſo, that a concordat cannot be valid ſo as to bind ſucceſſors, unleſs confirmed by the pope.

Concordat is alſo uſed, abſolutely, among the French, for an agreement concluded at Bologna in 1516, between pope Leo X. and Francis I. of France, for regulating the manner of nominating to benefices. The concordat ſerves in lieu of the pragmatic ſanction, which has been abrogated; or, rather, it is the pragmatic ſanction ſoftened and reformed. The king went in perſon to the parliament to offer the concordat to be regiſtered, and letters patent were made out, requiring all the judges and courts of juſtice to obſerve this act, and ſee it executed. The parliament, after deliberating a month upon this important matter, concluded not to regiſter the concordat, but to obſerve ſtill the pragmatic ſanction, unleſs the former edict was received and eſtabliſhed in as great an aſſembly as that was, which publiſhed the latter in the reign of Charles VII. And when, by violence and force, they were obliged to publiſh the concordat, they joined to the publication a ſolemn proteſt and an appeal from the pope to the next general council, into both which meaſures the univerſity and the clergy entered with the greateſt alacrity and zeal. But royal and papal deſpotiſm at length prevailed. The chancellor De Prat, who was principally concerned in promoting the concordat, has been generally regarded as an enemy to the liberties of the Gallican church. The illuſtrious and learned Hainault has defended his memory againſt this accuſation, and juſtified the concordat as an equitable contract, and as a meaſure attended with fewer inconveniences, than the pragmatic ſanction. He obſerves, that by the king's being inveſted by the concordat with the privilege of nominating to the biſhoprics and vacant benefices of the firſt claſs, many corruptions and abuſes were prevented, which aroſe from the ſimoniacal practices that prevailed almoſt every where, while, according to the pragmatic ſanction, every church choſe its biſhop, and every monaſtery its abbot. He obſerves moreover, that this nomination was the natural right of the crown, as the moſt conſiderable part of the great benefices had been created by the kings of France; and he particularly inſiſts on this conſideration, that the right which Chriſtian communities have to chuſe their leaders, cannot be exerciſed by ſuch large bodies without much confuſion and many inconveniences; and that the ſubjects, by entruſting their ſovereign with the government of the ſtate, inveſt him, *ipſo facto*, with an authority over the church, which is a *part* of the ſtate, and its nobleſt branch. The moſt ſpecious objection that was made to the concordat was this: that, in return for the nomination to the vacant benefices, the king granted to the popes the annates, or firſt fruits, which had too long been complained of as an intolerable grievance. There is, however, no mention of this equivalent in the concordat. And it was by a papal bull that ſucceeded this compact, that the pontiffs claimed the payment of the firſt fruits, of which they had put themſelves in poſſeſſion in the year 1316, and which had been ſuſpended by the pragmatic ſanction.

As the concordat gave to the kings of France the abſolute right of ſucceeding to all the great, or what are called the conſiſtorial benefices, of the Gallican church; it was a very important edict. Since the eſtabliſhment of the pragmatic ſanction and of the concordat, the clergy of France in general (before the late Revolution) manifeſted leſs reſpect to the decrees of the papal court than the clergy of any other Catholic country. In all the diſputes which their ſovereign has had with the pope, they have almoſt conſtantly taken part with the former. Their independence on the court of Rome ſeems to have been principally founded on this act.

The concordat between the pope and the republic of Venice reſembles the former.

There is alſo a German concordat, made between the emperor Frederic III. and the princes of Germany, in 1448, relating to beneficiary matters, confirmed by pope Nicholas V.

Concordat, as it is now uſed in France, is a term that applies excluſively to an agreement or convention exchanged between the pope, Pius VII., and the French government, the 23d Fructidor, an. 9, or September the 10th, 1801. In this agreement the Roman catholic religion is acknowledged to be that of the majority of the French people; and the better to conſolidate the reſtoration of its worſhip, which had been almoſt totally neglected ſince the year 1792, the pope engages not to diſturb the proprietors or purchaſers of eſtates, which, before the French revolution of 1789, belonged to the church; and he acknowledges in the firſt conſul of the French government the ſame rights and prerogatives which the ancient government poſſeſſed. By virtue of the ſaid concordat, the whole territory of European France is divided into ten archbiſhoprics; *viz.* Paris, containing eight biſhoprics, Malines ſeven, Beſançon five, Lyons four, Aix four, Toulouſe five, Bourdeaux three, Bourges three, Tours ſeven, and Rouen four; and fifty biſhoprics; *viz.* Troyes, Amiens, Soiſſons, Arras, Cambray, Verſailles, Meaux, Orleans, Namur, Tournay, Aix la Chapelle, Treves, Gand, Liege, Mayence, Autun, Metz, Straſbourg, Nancy, Dijon, Mende, Grenoble, Valence, Chambéry, Nice, Avignon, Ajaccio, Digne, Cahors, Montpellier, Carcaſſonne, Agen, Bajonne, Poitiers, La Rochelle, Angoulême, Clermont, Saint Flour, Limoges, Le Mans, Angers, Nantes, Rennes, Vannes, Saint Brieux, Quimper, Coutances, Bayeux, Siez, and Evreux. The nomination to the ſees reſts with the French government; the pope only confirms each nomination by his canonical inſtitution, according to the forms anciently eſtabliſhed with regard to the Gallican church, whoſe privileges and immunities continue in full force. The biſhops, before they enter upon their functions, ſhall take before the firſt conſul, in perſon, the oath of fidelity which was in uſe before the change of government, expreſſed in the following terms; "I ſwear and promiſe to God, upon the holy evangeliſts, to preſerve obedience and fidelity to the government eſtabliſhed by the conſtitution of the French republic. I alſo promiſe to have no correſpondence, nor to aſſiſt at any council or cabal, either within the country or out of it, that ſhall be contrary to the cauſe of the public tranquillity; and if in my dioceſe, or elſewhere, I ſhall learn of any plot or machination prejudicial to the ſtate, I ſhall inform the government of it." The clergy of the ſecond order ſhall take the ſame oath before the civil authorities appointed by the government. The following prayer ſhall be recited at the end of divine ſervice in all the Catholic churches of France:

Domine, ſalvam fac rempublicam!
Domine, ſalvos fac conſules!

The biſhops ſhall make a new diviſion of pariſhes in their dioceſes, ſubject to the conſent of the government: the biſhops ſhall name the curés, ſubject to the approbation of the government. The biſhops may have a chapter in their cathedral, and a ſeminary in their dioceſe, but the government is not engaged to endow them. All the metropolitan, cathedral, parochial, and other churches, undiſpoſed of, ſhall be placed at the diſpoſal of the biſhops. The government engages to ſecure a ſuitable proviſion for the biſhops and curés, whoſe dioceſes and pariſhes ſhall be marked out by the new diviſion. The allowance of the archbiſhops ſhall be 15,000 livres annually, and that of the biſhops 10,000. Biſhops may add to their titles the qualification of "citoyen," or "monſieur." No man can be named a biſhop but a Frenchman, aged at leaſt 30 years, having an atteſtation of his morals delivered by a biſhop, and after an examination of his doctrine by a biſhop and two prieſts: nor ſhall biſhops quit their ſees without the permiſſion of the firſt conſul. Biſhops are required to viſit every year a part of their dioceſe, and the whole every five years. No clergyman ſhall be ordained as prieſt, who is not 25 years of age, and poſſeſſed of 300 livres annual revenue. The curés ſhall reſide in their pariſhes; and prieſts, who do not regularly belong to any dioceſe, ſhall not officiate. The clergy in general ſhall wear black clothes; and the biſhops violet-coloured ſtockings. There ſhall be a liturgy and a catechiſm for the French church. The names of the days ſhall be as in the ancient calendar; and Sunday ſhall be the day of reſt for the public functionaries; nor ſhall any other holidays, except Sundays, be kept without the conſent of the government. The bells ſhall only be rung for divine ſervice. The ſame temple ſhall be conſecrated only to one form of worſhip. The nuptial benedictions ſhall be only given by the clergy to thoſe who have been married by the civil officers.

With regard to the Proteſtant religion, no perſon ſhall exerciſe the miniſterial functions but a Frenchman; nor ſhall the Proteſtant churches and their miniſters have any connection with any foreign power. The miniſters and their communities ſhall pray for the proſperity of the French republic, and the conſuls. No doctrine, nor alteration of doctrine, ſhall be publiſhed or taught, without being firſt authorized by the government. The maintenance of the miniſters ſhall be provided for, wherever the property and oblations of the communities fall ſhort. The articles for the liberty of foundations, in the organic laws of the Catholic worſhip, ſhall be common to the Proteſtant churches. There ſhall be two ſeminaries, one in the eaſt of France, for the inſtruction of miniſters of the confeſſion of Augſburg; and the other at Geneva for the reformed churches. The profeſſors are to be named by the firſt conſul, and no miniſter to be appointed without a certificate of his having ſtudied in the ſeminary of his religion. The regulations of the ſeminaries are to be ſettled by the government. The reformed churches of France ſhall have paſtors, local conſiſtories, and ſynods. There ſhall be a conſiſtorial church for every 6000 ſouls of the ſame communion. Five conſiſtorial churches ſhall form the diſtrict of a ſynod. The number of miniſters or paſtors in the ſame conſiſtorial church cannot be increaſed without the authority of government; nor can the paſtors reſign without ſtating their motives to government, which ſhall approve or reject them. The title of election ſhall be preſented to the firſt conſul for his approbation. Each ſynod ſhall conſiſt of a paſtor and a notable of each church. The ſynods ſhall ſuperintend the celebration of worſhip and conduct of eccleſiaſtical affairs, and all their deciſions ſhall be ſubmitted for the approbation of government. The ſynods cannot aſſemble until they ſhall have received the permiſſion of government; nor ſhall any ſynodal aſſembly laſt more than ſix days.

The churches of the confeſſion of Augſburg ſhall have paſtors, local conſiſtories, inſpections, and general conſiſtories. The paſtors and conſiſtorial churches ſhall be ſubject to the regulations preſcribed for the reformed paſtors and churches. The churches of this confeſſion ſhall be ſubordinate to the inſpections. Five conſiſtorial churches ſhall form an inſpection, which is to aſſemble only by permiſſion of government. Each inſpection to chooſe an inſpector, and two laymen of ſuch choice to be confirmed by the firſt conſul. There are to be three general conſiſtories; one at Straſburg, for the Proteſtants of Augſburg, of the departments of the Upper and Lower Rhine; a ſecond at Mentz, for thoſe of the departments of the Sarte and Mont-Tonnerre; and the third at Cologne, for thoſe of the departments of the Rhine, Moſelle, and Roer.

Concordat *Militaire*, Fr., an agreement entered into by officers of the ſame corps, to eſtabliſh a fund or proviſion for one of them that quitted it. This agreement, however, was only tolerated in particular caſes and circumſtances, to which the chiefs ſeemed to conſent, without either openly, or with their ſignatures, giving their approbation to the ſame.

CONCORDIA, in *Ancient Geography*, a town of Italy, with the title of colony; placed by Ptolemy in the country of the Carni, but by Pliny in that of the Veneti, between Pons Liquentiæ and Tilavemptus. Eutropius and the Itinerary of Antonine place it in Venetia. It took the name of *Julia*, becauſe a colony had been ſent thither by Julius Cæſar.—Alſo, a town of Spain, placed by Ptolemy in Luſitania, ſuppoſed to have been the preſent *Tomar*.—Alſo, a town and Roman fortreſs of Gaul, in Germania Prima, between Brocomagum and Noviomagum, according to the Itinerary of Antonine.

Concordia, in *Geography*, a town of Italy, in the duchy of Mirandola, on the Sechia; 6 miles W. of Mirandola; between which cities there is a fine canal, which facilitates the communication of both.—Alſo, a town of Italy, in the country of Friuli; which, though in ruins, is the ſee of a biſhop, who reſides at Porto Gruaro.

CONCOTS, a town of France, in the department of the Lot; 3 leagues S.S.E. of Cahors.

CONCOU, in *Botany*, a name given by the people of Guinea to an herb which is in great eſteem with them for killing that troubleſome ſort of worm called the Guinea-worm, which breeds in their fleſh. They bruiſe the leaves, and mixing them with oil, apply them in form of a cataplaſm. The leaves of this ſhrub ſomewhat reſemble thoſe of the caggow, but they are thicker and ſtiffer, and are not ſo full of veins. They are broadeſt within one third of the baſe, and from thence they go tapering to each end. They are placed on long footſtalks of a fine green throughout. Phil. Tranſ. N° 232.

CONCOURES, in *Geography*, a town of France, in the department of the Aveiron, and diſtrict of Rhodez; 7 miles N.N.E. of Rhodez.

CONCOURSE, or CONCURRENCE, the reciprocal action of divers perſons or things co-operating toward the ſame effect or end.

The ſchoolmen diſtinguiſh two kinds of concurrence; *viz.* mediate, which conſiſts in giving a power or faculty to act; and immediate, which is a contemporary influence of one cauſe along with another, to produce an effect. Thus, the grandfather concurs mediately to the production of a grandſon, as he originally gives the power of generating to the father; but the father concurs immediately with the mother to the production of the ſame child. With reſpect to the agency of God, ſome divines maintain both theſe kinds of concurrence; others deny the latter. See CAUSE.

CONCOURSE, *Point of.* See FOCUS.

CONCQUE, Fr. A piece of artillery, of which the bore is wider towards the muzzle than towards the breech. It is alſo the name of a ſhell, which the ancients made uſe of in their armies inſtead of a trumpet.

CONCRESSAUT, or CONCORSAUT, in *Geography*, a town of France, in the department of the Cher, on the Saudre, almoſt ruined by the civil wars; 25 miles N. of Bourges.

CONCRETE, in the *School Philoſophy*, an aſſemblage, or COMPOUND.

CONCRETE, *Phyſical*, or a CONCRETE *body*, may denote any mixed body, or body compoſed of different principles; and conſequently, all ſenſible bodies whatever, as all bodies ariſe from a coalition of divers elements, or at leaſt of divers principles, matter, and form.

But, in ſtrictneſs, concrete is only uſed for thoſe compounds wherein the ingredients ſtill retain their diſtinct natures, nor are wholly converted into any new common nature.

Authors diſtinguiſh *natural* concretes and *artificial* ones: antimony is a *natural* concrete, and ſoap a *factitious* concrete.

CONCRETE *Juices.* See JUICES.

CONCRETE, *Logical*, or a CONCRETE *word*, called alſo *paronymum*, is that which has a compound ſignification, as denoting both the ſubject and ſome quality or accident of the ſubject, which gives it its denomination.

Such, *e. gr.* are *man*, *learned*, *white*; for *man* ſignifies as much as *having human nature*; *learned*, as much as *having learning*, &c. Hence, the word concrete is chiefly uſed to expreſs the union of qualities or quantities with the bodies or ſubjects, without any ſeparation, even in idea. The oppoſite term, whereby things are ſeparated in thought, is *abſtract*.

Concrete properly ſignifies a ſubject accompanied with its form or quality; as *pious*, *hard*, *white*: *abſtract*, on the contrary, expreſſes the form and quality without the ſubject, as *piety*, *hardneſs*, *whiteneſs*.

CONCRETE *Numbers*, are thoſe which are applied to expreſs or denote any particular ſubject: as two men, three pounds, two thirds of a ſhilling, &c.

Whereas, if nothing be connected with a number, it is taken abſtractedly or univerſally: thus, three ſignifies only an aggregate of three units; let thoſe units be men, pounds, or what you pleaſe.

CONCRETION, the act whereby ſoft bodies are rendered hard; or an inſenſible motion of the particles of a fluid or ſoft body, whereby they come to a conſiſtence.

The word is uſed indifferently for *induration*, *condenſation*, *congelation*, and *coagulation*.

CONCRETION is alſo uſed for the coalition of ſeveral little particles into a ſenſible maſs, called a CONCRETE; by virtue of which union, the body acquires this or that figure, and theſe or thoſe properties.

CONCRETION, in *Surgery*, from *concretio*, the adheſion or growing together of parts. This term alſo denotes the impacting or cohering of ſubſtances together, ſo as to form a maſs; as in the ſanguineous concretion, the bilious or biliary concretion, the calculous concretion, &c. The coaleſcence of parts which ought to be ſeparate, as of the fingers and eyelids, might be rather called agglutination or coheſion.

Membranes and other parts may adhere together, either from natural or accidental cauſes; but the moſt frequent cauſe of external concretions is an ulceration or abraſion of the ſkin, ſo that two ſurfaces lying in contact ſhall unite by inflammation and reciprocal granulation. In all ſuch caſes, where an operation is practicable and neceſſary, the ſurgeon muſt ſeparate the united parts with a ſcalpel, and keep them aſunder during the cure. See STONE and CALCULUS.

CONCUBINAGE ſometimes expreſſes a criminal, or prohibited commerce between the two ſexes; in which ſenſe it comprehends *adultery*, *inceſt*, and *ſimple fornication*.

Promiſcuous concubinage is productive of a great variety of evils, and tends not only to the corruption, but to the ultimate deſtruction, both of individuals and of ſociety. It is not only ineffectual to promote love, and the tender affections, either between perſons themſelves, or towards their offspring, but it contributes towards exciting and maintaining endleſs jealouſies and quarrels among mankind. The great and radical miſchief attending unreſtrained promiſcuous concubinage in a ſtate of ſociety, conſiſts in its tendency to diminiſh marriages, and thus to defeat the ſeveral beneficial purpoſes reſulting from this inſtitution. (See MARRIAGE.) It diſcourages marriage by weakening the force of a very urgent motive and temptation to it, ariſing from the intention of the original former of mankind, and the conſtitution of human nature. "The male part of the ſpecies," ſays Dr. Paley, "will not undertake the incumbrance, expence, and reſtraint of married life, if they can gratify their paſſions at a cheaper price; and they will undertake any thing rather than not gratify them."

A juſt idea may be formed of the magnitude of this miſchief, by attending to the importance and variety of the uſes to which marriage is ſubſervient; and by duly conſidering that the malignity and moral quality of each crime are not to be eſtimated by the particular effect of one offence, or of one perſon's offending, but by the general tendency and conſequence of crimes of the ſame nature. The libertine may not be conſcious that thoſe irregularities hinder his own marriage; from which, as he may allege, he is deterred by different conſiderations; nor may he perceive, or be diſpoſed to acknowledge, that his indulgences hinder the marriage of others; but it behoves him to reflect, what would be the conſequence of univerſal licentiouſneſs in this reſpect, and what ſhould prevent its becoming univerſal, if it be innocent or allowable in him. Moreover, fornication ſupports proſtitution; and proſtitution entails on its victims almoſt certain miſery, occaſioned by the indigence, diſeaſe, and inſult, to which theſe wretched outcaſts of ſociety, who infeſt populous cities, are ſubject; the whole aggregate of which is a general conſequence of fornication, and to the increaſe and continuance of which, every act and inſtance of fornication contribute. Beſides, fornication promotes habits of ungovernable lewdneſs, which introduce the more aggravated crimes of ſeduction, adultery, violation, &c.; to which we may add, in this connection, that the criminal commerce of the ſexes depraves the mind and moral character more than any ſingle ſpecies of vice whatſoever; theſe indulgences prepare an eaſy admiſſion for every other crime: in low life, they are uſually the firſt ſtage in men's progreſs to the moſt deſperate villainies; and, in high life, to that lamented diſſoluteneſs of principle which manifeſts itſelf in a profligacy of public conduct, and a contempt of the obligations of religion and moral probity. Habits of libertiniſm alſo incapacitate and indiſpoſe the mind for all intellectual, moral, and religious pleaſures, which would very much contribute to every man's happineſs.

It deſerves further to be conſidered, that fornication perpetuates a diſeaſe, which may be accounted one of the ſevereſt maladies of human nature; and the effects of which are ſaid to contaminate the conſtitution of even diſtant generations. This dreadful malady, the ſevereſt ſcourge, ſays Dr. Robertſon, (Hiſt. of America, vol. ii. p. 87), with which, in this life, offended Heaven chaſtens the indulgence of criminal deſires, ſeems to have been peculiar to the Americans; and he adds, that by communicating it to their conquerors, they have not only amply revenged their own wrongs, but by adding this calamity to thoſe which formerly embittered human life, they have, perhaps, more than counterbalanced all the benefits which Europe has derived from the diſcovery of the New World.

Dr. Hartley, in his "Obſervations on Man," (p. 443), remarks, that the ſhameful, loathſome, and often fatal diſeaſe, which peculiarly attends the vice of lewdneſs, may be conſidered as a moſt unqueſtionable evidence of the Divine Will. This diſeaſe, with all its conſequences, would ſoon ceaſe among mankind, could they be brought under the reſtraints of lawful marriage; but muſt ever continue, whilſt licentiouſneſs continues. Without this check, however, the licentiouſneſs which has always been obſerved to follow improvements in arts and politeneſs, and to attend upon bodies politic in their declenſion, and which the corruption of the Chriſtian religion in ſome, and the diſbelief of it in others, have, in a manner, authorized, would have brought on utter diſſoluteneſs in this weſtern part of the world, ſuch as would have been inconſiſtent with the very exiſtence of regular government. Nay, it may be, that this will ſtill be the caſe, and that we are haſtening to our period, through the great wickedneſs of the world in this reſpect particularly, though our lives, as a body politic, be ſomewhat prolonged by this correction.

If we appeal to the Chriſtian ſcriptures on the ſubject of this article, it is certain that theſe ſacred writings condemn fornication abſolutely and peremptorily, and that they claſs this crime with murders, thefts, falſe witneſs, and blaſphemies. Beſides, the aggravated ſin of idolatry is repreſented by adultery and fornication in the prophetic writings. Although the ſcriptures give no ſanction to thoſe auſterities which have been impoſed upon the world under the name of Chriſtianity, as the celibacy of the clergy, the practice of perpetual virginity, the "prohibitio concubitûs cum gravidâ uxore;" yet, with a juſt regard to the condition and intereſt of the human ſpecies, they have provided, by the marriage of one man with one woman, an adequate gratification for the propenſities of their nature, and have *reſtrained* them to that gratification. The avowed toleration, and in ſome countries the licenſing, taxing, and regulating of public brothels (ſee BAWDY-HOUSE), have appeared like a ſanction of fornication, and have contributed, with other concurring cauſes, ſo far to vitiate the public opinion, that there is no practice, the immorality of which is ſo little thought of or acknowledged, although there are few in which it can be more eaſily and more ſatisfactorily evinced. The legiſlators who have patronized receptacles of proſtitution ought to have foreſeen this effect, and alſo to have conſidered, that whatever facilitates fornication, diminiſhes marriage. As to the uſual apology for this relaxed diſcipline, the danger of greater enormities if acceſs to proſtitutes were too ſtrictly watched and prohibited, "it will be time enough," ſays Dr. Paley, "to look to that, when the laws and magiſtrates have done their utmoſt." After all, theſe fears are without foundation in experience. The men are in all reſpects the moſt virtuous, in countries where the women are the moſt chaſte.

In its more reſtrained ſenſe, concubinage is uſed for a man's and a woman's cohabiting together in the way of marriage without having paſſed the ceremony thereof.

This ſpecies of cohabitation is, without doubt, diſtinguiſhable from vagrant concubinage, and by reaſon of its reſemblance to marriage, may be thought to participate of the ſanctity and innocence of that ſtate. In modern phraſe, it is denominated "the keeping of miſtreſſes," under the ſuppoſed favourable circumſtance of mutual fidelity. For this practice the following kind of apology has been ſometimes alleged:

"That the marriage rite being different in different countries, and in the ſame country among different ſects, and with ſome, ſcarcely any thing; and, moreover, not being preſcribed or even mentioned in ſcripture, can be regarded only as a form or ceremony of human invention; and that, conſequently, if a man and woman betroth and confine themſelves to each other, their intercourſe muſt be the ſame, as to all moral purpoſes, as if they were legally married; for the addition or omiſſion of that which is a mere form and ceremony can make no difference in the ſight of God, or in the actual nature of right and wrong."

To this ſpecious ſort of reaſoning, archdeacon Paley has replied:

1. If the ſituation of the parties be the ſame thing in marriage, why do they not marry? 2. If the man chooſe to have it in his power to diſmiſs the woman at his pleaſure, or to retain her in a ſtate of humiliation and dependence inconſiſtent with the rights which marriage would confer upon her, it is not the ſame thing. 3. It is not at any rate the ſame thing with reſpect to the children. Moreover, as to the marriage rite being a mere form, and that alſo variable, the ſame may be ſaid of ſigning and ſealing of bonds, wills, deeds of conveyance, and the like, which yet make a great difference in the rights and obligations of the parties concerned in them. And with reſpect to the rite not being appointed in ſcripture, the ſcriptures forbid fornication, that is, cohabitation without marriage, leaving to the law of each country to pronounce what is, or what makes, a marriage; in like manner as they forbid theft, that is, the taking away of another's property, leaving it to the municipal law to fix what makes the thing property, or whoſe it is, which alſo,

as well as marriage, depends on arbitrary and mutable forms. Independently of the injunctions of ſcripture, the plain account of the queſtion ſeems to be this; it is immoral, becauſe it is pernicious, that man and woman ſhould cohabit, without undertaking certain irrevocable obligations, and mutually conferring certain civil rights: if, therefore, the law has annexed theſe rights and obligations to certain forms ſo that they cannot be ſecured or undertaken by any other means, which is the caſe in this inſtance (for whatever the parties may promiſe to each other, nothing but the marriage ceremony can make their promiſe irrevocable), it becomes in the ſame degree immoral, that men and women ſhould cohabit without the interpoſition of theſe forms. Paley's Principles of Moral and Political Philoſophy, vol. 1. b. 3. c. 2.

Concubinage was anciently tolerated: the Roman law calls it an allowed cuſtom, *licita conſuetudo*. When this expreſſion occurs in the conſtitutions of the Chriſtian emperors, it ſignifies what we now call a "marriage in conſcience."

The concubinage tolerated among the Romans in the time of the republic, and of the heathen emperors, was that between perſons not capable of contracting marriage together: nor did they even refuſe to let inheritances deſcend to children which ſprung from ſuch a tolerated cohabitance.

Concubinage between ſuch perſons they looked on as a kind of marriage, and even allowed it ſeveral privileges: but then this concubinage was confined to a ſingle perſon, and was of perpetual obligation, as much as marriage itſelf. Hottoman obſerves, that the Roman laws had allowed of concubinage long before Julius Cæſar made that law whereby every one was allowed to marry as many wives as he pleaſed. The emperor Valentinian, Socrates tells us, allowed every man two.

Concubinage is alſo uſed for marriage performed with leſs ſolemnity than the formal marriage; or a marriage with a woman of inferior condition, and to whom the huſband does not convey his rank, or quality.

Cujas obſerves, that the ancient laws allowed a man to eſpouſe, under the title of concubine, certain perſons, ſuch as were eſteemed unequal to him, on account of the want of ſome qualities requiſite to ſuſtain the full honour of marriage. He adds, that though concubinage was beneath marriage, both as to dignity, and civil effects; yet was concubine a reputable title, very different from that of *miſtreſs* among us.

The commerce was eſteemed ſo lawful, that the concubine might be accuſed of adultery in the ſame manner as a wife.

This kind of concubinage is ſtill in uſe in ſome countries, particularly in Germany, under the title of a *half-marriage*, *morgengabic marriage*, or *marriage with the left hand*; alluding to the manner of its being contracted, *viz.* by the man's giving the woman his left-hand inſtead of the right.

This is a real marriage, though without ſolemnity: the parties are both bound for ever; though the woman be thus excluded from the common rights of a wife, for want of quality or fortune.

The children of concubines were not reputed either legitimate or baſtards, but natural children, and were capable only of donations.

They were deemed to retain the low rank of the mother; and were on this ground unqualified for inheriting the effects of the father.

Concubinage, in a *Legal Senſe*, is uſed as an exception againſt her that ſueth for dower, alleging thereby, that ſhe was not a wife lawfully married to the party, in whoſe lands ſhe ſeeks to be endowed, but his concubine. Brit. c. 107. Bract. lib. iv. tract. 6. cap. 8.

CONCUBINE, a woman whom a perſon takes to cohabit with him, in the manner, and under the character, of a wife, without being authorized thereto by a legal marriage.

Concubine is alſo uſed for a real, legitimate, and only wife, diſtinguiſhed by no other circumſtances but a diſparity of birth or condition between her and the huſband. Du-Cange obſerves, that one may gather from ſeveral paſſages in the epiſtles of the popes, that they anciently allowed of ſuch concubines. The ſeventeenth canon of the firſt council of Toledo declares, that he, who with a faithful wife keeps a concubine, is excommunicated; but that if the concubine ſerved him as a wife, ſo that he had only one woman, under the title of concubine, he ſhould not be rejected from communion: which ſhews that there were legitimate wives under the title of concubines.

In effect, the Roman laws did not allow a man to eſpouſe whom he pleaſed; there was required a kind of parity, or proportion, between the conditions of the contracting parties; but a woman of inferior condition, who could not be eſpouſed as a wife, might be kept as a concubine; and the laws allowed of it, provided the man had no other wife.

It is certain the patriarchs had a great number of wives, and that theſe did not all hold the ſame rank; ſome being ſubaltern to the principal wife; which were what we call concubines, or half-wives. The Romans prohibited a plurality of concubines, and only had regard to the children iſſuing from a ſingle concubine, becauſe ſhe might become a legitimate wife. Solomon had 700 wives, and 300 concubines: the emperor of China has ſometimes two or three thouſand concubines in his palace. Q. Curtius obſerves, that Darius was followed in his army by 365 concubines, all in the equipage of queens; and Diodorus Siculus ſays, that he maintained as many as the days of the year. Artaxerxes had by his concubines 115 children. The concubines were introduced to the Perſian king, each in her turn; whence ſome have concluded, that the ancient Perſian year conſiſted of 360 days, ſince ſeveral of the Perſian monarchs had this number of concubines, who went to their kings in conſtant courſe.

CONCUPISCENCE, among divines, an irregular deſire, appetite, or luſt after carnal things, inherent in human nature.

The dominion or prevalence of concupiſcence, according to F. Malebranche, is what we call original ſin.

The origin of concupiſcence he aſcribes to thoſe impreſſions made on the brain of our firſt parents at their fall; which are ſtill tranſmitted and continued on thoſe of their children; for as animals produce their like, and with like traces in the brain (whence the ſame ſympathies and antipathies in the ſame kind; and whence the ſame conduct on the ſame occaſions); ſo our firſt parents, after their fall, received ſuch deep traces in the brain, by the impreſſion of ſenſible objects, that they might well be ſuppoſed to communicate them to their children.

The ſchoolmen uſe the term *concupiſcible appetite* for the deſire we have of enjoying any good; in oppoſition to *iraſcible appetite*, whereby we eſchew what is evil.

CONCURRENCE. See Concourse.

CONCURRING, or Congruent *Figures*, in *Geometry*, ſuch as, being laid upon one another, do exactly correſpond to, and cover one another, and conſequently muſt be equal among themſelves. Thus, triangles having two ſides and the contained angle equal each to each, appear to be equal to one another in all reſpects. See Congruity.

CONCUSSION *crimen repetundarum*, in *Juriſprudence*, is the abuſe of power by ſome perſon entruſted with a public commiſſion or employment; by extorting money from thoſe under his power or command. This crime is taken notice of in the heads of the Digeſt, or Code—*ad legem Juliam repetundarum;* and it is to be obſerved, that he who gave a bribe contrary to the oath he had taken, might be proſecuted as well as the receiver: and that the judge who was corrupted was deemed guilty of concuſſion, as much as he who purchaſed property which was in a courſe of litigation. The magiſtrates were even forbidden to acquire any thing by way of purchaſe, donation, or otherwiſe, in the provinces wherein they reſided, under pain of being guilty of concuſſion.

The crime of concuſſion was not ranked in the number of public offences, except when committed by a magiſtrate; when committed by a perſon of inferior ſtation, it was only a private crime; but it is not the quality of the perſon which renders the crime public or private, but the nature of the crime itſelf.

Concussion, in *Surgery*, from *concutio*, a ſhaking together. This term is moſtly applied to a violent commotion of the body, and eſpecially of the brain; but a concuſſion of the nervous ſyſtem in general, or of the ſpinal marrow in particular, may produce the ſame train of ſymptoms in a partial degree, as a commotion of the brain does in the whole body. A concuſſion of the brain may be occaſioned not only by blows on the head, but alſo by violence inflicted upon other parts of the body. It is frequently occaſioned by a fall upon the thighs when ſtretched out ſtraight, or upon the breech; it is alſo obſerved in caſes of contuſion of the face, and fractured bones, occaſioned by a fall from a conſiderable height, in gun-ſhot wounds attended with a ſplintering of the bones, and, in general, in every caſe of external violence attended with conſiderable commotion of the whole body. However, from whatever cauſe it may ariſe, it always requires ſurgical treatment.

Moſt of the ſymptoms attending compreſſion of the brain occur alſo in concuſſion; but in a compreſſed ſtate of the brain they are more permanent. See Compression.

There is no diſcharge of blood from the eyes, noſe, or ears, which frequently happens in compreſſion; and inſtead of that apoplectic ſtertor in breathing which accompanies compreſſion, the patient ſeems to be in a ſound and natural ſleep. The pulſe is irregular and ſlow in compreſſion, and grows ſtronger and fuller by blood-letting; but in concuſſion it is weaker, being ſoft and equal, and ſinks by blood-letting. There are beſides, convulſions in compreſſions, which are not obſerved in a ſtate of concuſſion. The ſymptoms ariſing from concuſſion come on immediately after the injury is received. In the violent degrees of theſe, the patient remains quite inſenſible; the pupils are much dilated, and do not contract though the eyes be expoſed to the ſtrongeſt light.

In more violent accidents, eſpecially when the patient is rendered inſenſible, it is extremely difficult to diſtinguiſh between concuſſion and depreſſion; for ſymptoms which have been ſuppoſed to ariſe entirely from concuſſion, have, after death, been found to be owing to extravaſation or undiſcovered fracture; and extravaſation has been blamed, when, on diſſection, not the leaſt morbid appearance could be diſcovered.

The ſymptoms conſequent upon concuſſion of the brain are various, in proportion to the different degrees of the violence inflicted. In its ſlighteſt degree, it produces ſtupor and inclination to ſleep, debility of the intellectual and corporeal faculties, inſenſibility, or paralyſis of ſome particular part. In the ſecond degree, the patient lies without ſenſation and motion in a ſtate of profound coma, from which he cannot be rouſed. But at the ſame time he is generally reſtleſs, toſſes about, ſpeaks much in his ſleep, ſometimes looks up, ſtares wildly, raves, is affected with convulſions, and generally his pulſe betokens irritation. In the third degree, death ſupervenes, either immediately, or as the ſymptoms increaſe in violence.

Theſe ſymptoms, however, are not always of the ſame nature and origin, and therefore require different methods of treatment. Thus the blood-veſſels of the brain may be weakened in conſequence of the violence inflicted; the blood may be preternaturally accumulated in them, and dilate them, to which ſometimes alſo a congeſtion in the head contributes. Sometimes, alſo, the external violence acts upon the ſubſtance of the brain itſelf and the whole nervous ſyſtem, either by the irritation or by the debility and paralytic ſtate which it induces: in the firſt of theſe caſes ſpaſmodic affections, reſtleſſneſs, want of ſleep, or coma attended with delirium and convulſions, are obſerved, and in the ſecond the patient is thrown into a ſtate ſimilar to ſyncope.

Before the external violence has been inflicted, it may happen that the patient may have been in a ſtate of great anxiety and fear, and he may have been greatly terrified by the danger whilſt it was ſtill impending, in which caſes the conſequences of theſe violent emotions of the mind, may be miſtaken for effects of a concuſſion of the brain. The patient is in a very different ſtate when the injury has been inflicted whilſt he was intoxicated, or in anger, or when his ſtomach was full. Not unfrequently alſo ſome of the ſymptoms proceed from leſions of other parts of the body more remote from the head, or from collateral cauſes, eſpecially from inflammatory, and bilious complaints in the viſcera; which frequently produce not only a determination towards the head, but alſo various other ſymptoms indicative of irritation.

All theſe ſymptoms the ſurgeon muſt take into mature conſideration, in order to be able to form a proper judgment concerning the ſtate of the patient in whom he diſcovers ſymptoms of concuſſion of the brain. Theſe ſymptoms are commonly of a fourfold nature; that is, they are ſymptoms indicative of compreſſion of the brain, and ariſe from the congeſtions in the veſſels; or they are ſymptoms of debility and inactivity of the concuſſed nervous ſyſtem; or they are ſymptoms of irritation in the nervous ſyſtem; or finally, they are conſequences of preternatural irritating cauſes in the abdominal viſcera. Commonly the ſymptoms belonging to each of theſe four different heads are combined; but frequently thoſe of one claſs are more violent than thoſe of the reſt, and to this circumſtance the ſurgeon muſt eſpecially attend in regulating his method of treatment.

With reſpect to the cure, much alſo depends upon making the proper diſtinction between the ſymptoms of concuſſion and thoſe of extravaſation. In many caſes this may eaſily be done; for the ſymptoms of concuſſion come on immediately after the violence has been inflicted, whilſt thoſe of extravaſation generally ſupervene within a longer or ſhorter time after. This criterion is however not always to be depended upon, nor diſcoverable in every caſe; for when the patient was alone at the time when the accident happened, and is now deprived of his ſenſes, the ſurgeon cannot aſcertain whether the ſymptoms followed the accident immediately.

If the ſymptoms abate after the uſe of antiphlogiſtic remedies, ſuch as blood-letting, evacuations, glyſters, waſhing with cold water, &c. they ought to be continued; but in the contrary caſe, they are to be relinquiſhed and an oppoſite method of treatment adopted. The effects of blood-letting alone ſometimes form an important criterion; for in caſes of concuſſion of the brain it frequently lowers the pulſe to a great degree, nay, even aggravates the ſymptoms; whilſt in extravaſations, even though it be frequently repeated, it produces a far leſs deciſive effect upon the pulſe, and frequently alleviates the ſymptoms.

Amongſt the various remedies that have been recommended in concuſſions of the brain, blood-letting is moſt generally employed; but it ought to be moderate. Topical detraction of blood from the head has ſometimes been found uſeful. Purgatives are always very ſerviceable, but in general it is neceſſary to adminiſter them in large and repeated doſes. Still more beneficial are emetics, and amongſt theſe tartar emetic and vitriolated zinc commonly prove the moſt efficacious; though, on account of the inſenſibility of the patient, they muſt uſually be adminiſtered in very large doſes, in order to produce their effect. Many recommend alſo ſtimulating glyſters, and various other ſtimulating remedies; ſuch as the volatile alkalies, bliſters applied to the head, and it is affirmed that ſome have even adminiſtered wine internally with the beſt effects. Cold fomentations are here particularly uſeful, as they are adapted to all caſes, as are likewiſe all the remedies uſually employed in ſyncope. Where there are ſymptoms of irritation, ſpaſms, and convulſions, antiſpaſmodics are frequently found to produce great benefit; and in theſe caſes Dover's powder is particularly recommended. Before uſing it, the warm bath, and when the patient is plethoric, blood-letting is preſcribed. This remedy muſt be continued as long as the ſymptoms remain, and it muſt be repeated when they return. Alſo a mixture of three parts of Vin. Antimonii and one part Tinct. Theb. given in doſes of ten drops every four hours, is found very uſeful. The uſe of laudanum alone has ſometimes removed the ſymptoms of concuſſion.

Notwithſtanding that all the above mentioned remedies ſtand recommended by authentic experience, yet as they are ſo oppoſite to each other in their properties, it cannot poſſibly be adviſeable to preſcribe them all together, or any ſingle one in all caſes; and the ſurgeon has therefore in every ſingle caſe to chooſe thoſe remedies that are particularly adapted to remove the moſt urgent ſymptoms of the diſeaſe. Thus, when the ſymptoms of preternatural repletion of the veſſels of the brain are urgent, he muſt employ blood-letting, cold fomentations, evacuations, and glyſters; to the latter of which it has been particularly recommended to add powder of ſquills: when the urgent ſymptoms are thoſe of debility bordering on ſyncope, he may uſe volatile alkali, wine, epiſpaſtics, cold fomentations, emetics, and other tonic remedies; when the ſpaſmodic ſymptoms are the moſt prominent, Dover's powder, Tinct. Antimon. and laudanum; when the ſymptoms of bilious effuſions prevail, emetics and purgatives.

As there is always reaſon at firſt to ſuſpect an accumulation of blood, and to apprehend inflammation, it will almoſt always be adviſeable firſt to draw blood, unleſs it ſhould be contraindicated by any peculiar ſymptoms. Stimulants and tonics will produce more benefit after the ſymptoms have continued for ſome time, than if adminiſtered at the beginning. If after the firſt or ſecond blood-letting, the pulſe ſinks whilſt the other ſymptoms remain the ſame, or are even aggravated, it ought not to be perſiſted in, but a contrary mode of practice is to be attempted. We may expect advantage from blood-letting, purgatives, and emetics, when the pulſe is full, hard, and quick; from antiſpaſmodics, when it is ſmall and hard; and from ſtimulant and tonic remedies, when it is ſmall and ſoft. Neutral ſalts, gentle purgatives, and blood-letting, may be employed when the patient is ſtrong, vigorous, plethoric, and florid; ſtimulant antiſpaſmodics, when he is weakly, very irritable, pale, and cold.

Finally, we muſt alſo attend to the ſtate in which the patient has been before the injury: ſhould he have received it whilſt in a ſtate of intoxication, cooling evacuants, and blood-letting are neceſſary; if he has received it whilſt his ſtomach was full, or whilſt in a paroxyſm of anger, emetics and purgatives are indicated; if whilſt under the influence of great fear or apprehenſion, tonic and antiſpaſmodic remedies will be proper. Moreover, the head of the patient muſt be carefully guarded againſt all motion and concuſſion during the courſe of the cure.

Should the patient recover under the uſe of the above-mentioned remedies, he muſt ſtill for ſome time after carefully avoid all commotion of the head, and whatever tends to accelerate the circulation, as anger, wine, violent bodily exerciſe; it is alſo proper to continue ſtill for ſome time, to waſh or bathe the head in cold water; and ſometimes to take tonic remedies, ſuch as Peruvian bark, acid of vitriol, &c. When the patient, though in other reſpects recovered, ſtill continues to labour under debility or paralyſis of particular parts, theſe complaints may ſometimes be removed by the continued uſe of internal and external tonics and ſtimulants, eſpecially volatile alkali, emetics, bliſters, electricity, &c. But when the ſymptoms increaſe in ſpite of the moſt careful treatment, the ſurgeon is authorized, eſpecially when the diagnoſis is doubtful, to ſuppoſe an extravaſation, and to trepan the part that has been injured. And ſuppoſing even that the ſurgeon has drawn a falſe concluſion, the operation of the trepan, if ſkilfully performed, will do no harm, nay, may even in ſome inſtances be productive of benefit, in conſequence of the diſcharge of blood which it occaſions.

On this important ſubject Mr. Abernethy's obſervations deſerve particular attention. He is of opinion that the effects of concuſſion have not been juſtly deſcribed by authors, nor the ſymptoms related by them thoſe which uſually occur. In his Surgical Eſſays, he, therefore, ſelects two caſes out of many others, in order to ſhew what really are the common conſequences of this injury named concuſſion.

"The whole train of ſymptoms following a concuſſion of the brain," ſays he, "may, I think, be properly divided into three ſtages. The firſt is, that ſtate of inſenſibility and derangement of the bodily powers which immediately ſucceed the accident. While it laſts, the patient ſcarcely feels any injury that may be inflicted on him. His breathing is difficult, but, in general, without ſtertor; his pulſe intermitting, and his extremities cold. But ſuch a ſtate cannot laſt long; it goes off gradually, and is ſucceeded by another, which I conſider as the ſecond ſtage of concuſſion. In this, the pulſe and reſpiration become better, and though not regularly performed, are ſufficient to maintain life, and to diffuſe warmth over the extreme parts of the body. The feeling of the patient is now ſo far reſtored that he is ſenſible if his ſkin be pinched; but he lies ſtupid, and inattentive to ſlight external impreſſions. As the effects of concuſſion diminiſh, he becomes capable of replying to queſtions put to him in a loud tone of voice, eſpecially when they refer to his chief ſuffering at the time, as pain in the head, &c. otherwiſe, he anſwers incoherently, and as if his attention was occupied by ſomething elſe. As long as the ſtupor remains, the inflammation of the brain ſeems to be moderate; but as the former abates, the latter ſeldom fails to increaſe; and this conſtitutes the third ſtage, which is the moſt important of the ſeries of effects proceeding from concuſſion.

"Theſe ſeveral ſtages vary conſiderably in their degree and duration; but more or leſs of each will be found to take place in every inſtance where the brain has been violently ſhaken. Whether they bear any certain proportion to each other or not, I do not know. Indeed this will depend upon ſuch a variety of circumſtances in the conſtitution, the injury, and the after treatment, that it muſt be difficult to determine.

"With regard to the treatment of concuſſion, it would appear, that in the firſt ſtage very little can be done; and perhaps, what little is done, had better be omitted, as the brain and nerves are probably inſenſible to any ſtimulants that can be employed. From a looſe, and, I think, fallacious analogy between the inſenſibility in fainting, and that which occurs in concuſſion, the more powerful ſtimulants, ſuch as wine, brandy, and volatile alkali, are commonly had recourſe to, as ſoon as the patient can be got to ſwallow. The ſame reaſoning which led to the employment of theſe remedies in the firſt ſtage, in order to recal ſenſibility, has given a kind of ſanction to their repetition in the ſecond, with a view to continue and increaſe it.

"But here the practice becomes more pernicious, and leſs defenſible. The circumſtance of the brain having ſo far recovered its powers, as to carry on the animal functions in a degree ſufficient to maintain life, is ſurely a ſtrong argument that it will continue to do ſo, without the aid of means which probably tend to exhauſt parts already weakened by the violent action they induce.

"And it ſeems probable that theſe ſtimulating liquors will aggravate that inflammation which muſt ſooner or later enſue. The acceſs of it, in the caſes which I have related, is ſufficiently evident; and its cure is to be effected by the common methods. The great benefit of evacuations was, in thoſe caſes, very evident."

After ſome further remarks in oppoſition to the cordial plan of treatment, and the relation of a fatal caſe of ſimple concuſſion, in which that ſyſtem would have been manifeſtly hurtful, Mr. Abernethy adverts to the very deſirable object of pointing out the marks by which we may diſtinguiſh between compreſſion and concuſſion of the brain; for theſe, he apprehends, may in general be diſtinguiſhed.

"As far as my obſervation goes," ſays he, "the inſenſibility is much leſs in concuſſion, eſpecially after a ſhort time has elapſed. Patients in this caſe, though they ſeem reluctant to anſwer queſtions, yet complain much if their heads are moved; and in thoſe inſtances where it was judged neceſſary to inſpect the bone, I have generally found they made great complaint during the operation. The pupils alſo are uſually more contracted than in compreſſion of the brain, the muſcles of the limbs retain their natural ſtate of tone, and reſpiration is performed with little or no ſtertor, though the pulſe generally intermits in a very conſiderable degree. In the ſlighter caſes of concuſſion, the ſickneſs of the patient is often very great.

"But, in caſes of compreſſion of the brain, circumſtances very much the reverſe of thoſe juſt related take place; the ſenſibility is much diminiſhed in proportion to the degree of the injury; from this cauſe alſo the pupils are dilated, and the limbs relaxed; the reſpiration is attended with ſtertor; and the pulſe is ſubject to much leſs intermiſſion."

COND, Con, or Conn, in *Sea Language,* ſignifies to guide or conduct a ſhip in her right courſe.

He that conds her, ſtands aloft with a compaſs before him, and gives the word of direction to the man at the helm how he is to ſteer. See Steering.

If the ſhip go before the wind, or, as they call it, betwixt the ſheets, the word is either *ſtarboard,* or *port the helm*; according as the conder would have the helm put to the right or left ſide of the ſhip, upon which the ſhip always goes the contrary way.

If he ſays, *helm a mid ſhip,* he would have the ſhip to go right before the wind, or directly between her two ſheets.

If the ſhip ſail by wind, or on a quarter wind, the word is, *aloof, keep your luff, fall not off, veer no more, keep her to, touch the wind, have a care of the lee-latch:* all which expreſſions are of the ſame import, and imply that the ſteerſman ſhould keep the ſhip near the wind.

On the contrary, if he would have her ſail more large, or more before the wind, the word is, *eaſe the helm, no near, bear up.*

If he cries *ſteady,* it means, keep her from going in and out, or making yaws (as they call it), howſoever ſhe ſails, whether large or before a wind; and when he would have her go juſt as ſhe does, he cries *keep her thus, thus,* &c

CONDA, or Kond, ſignifies fortreſs, and often occurs as a termination of words in the ſouth part of India, in this ſenſe, as *cotta* and *coté,* which have the ſame ſignification, do in the north.

CONDABORA, in *Ancient Geography,* a town of Spain, placed by Ptolemy in Celtiberia.

CONDALIA, in *Botany,* Cavanilles, Icon. tab. 525. Claſs and order, *pentandria monogynia.* Nat. Ord. *rhamni.*

Gen. Ch. *Cal.* one-leafed, with five lanceolate diviſions, permanent. *Cor.* none. *Stam.* five. *Piſt.* Germ ſuperior, egg-ſhaped, ſurrounded by the glandular diſk of the calyx; ſtyle one; ſtigma emarginate. *Peric.* Drupe egg-ſhaped; nut one-celled.

Sp. C. *parvifolia.* A ſhrub. *Branches* numerous, ſpinous. *Leaves* ſmall, egg-ſhaped, acute, cluſtered in the axils of the ſpines. *Flowers* yellowiſh, very ſmall, axillary. Ruiz and Pavon, in their Flora Peruvienſis, have given the ſame name to another genus, conſiſting of ſome herbaceous plants diſcovered by them in Peru. Claſs and order, *tetrandria monogynia.*

Gen. Ch. *Cal.* one-leafed, four-toothed, permanent. *Cor.* monopetalous, funnel-ſhaped; tube inflated; border with four lanceolate diviſions. *Stam.* four, very ſhort. *Piſt.* Germ inferior; ſtyle bifid. *Peric.* Berry egg-ſhaped, crowned by the calyx, hollow, ſpongy, two-celled. *Seeds* ſeveral, attached to a pedicelled receptacle, adnate to the interior of the partition.

CONDALUS, in *Antiquity,* a kind of ring uſually worn by ſlaves.

CONDAMINE, Charles-Marie de la, in *Biography,* a celebrated traveller, was born at Paris in the year 1701. In early life he diſtinguiſhed himſelf as a military man; but quitting the profeſſion of arms for the purpoſe of indulging a laudable curioſity, and a thirſt for natural ſcience, he diligently ſurveyed all the countries bordering on the coaſts of the Mediterranean, and travelled into various parts of Leſſer Aſia, Egypt, and Turkey. He was elected a member of the Academy of Sciences, and propoſed a voyage to the equator, in order to meaſure a degree of the meridian. In 1736 he went, with other mathematicians, to Peru for this purpoſe, and exhibited the greateſt aſſiduity and ſkill in accompliſhing the work. On his return he deſcended the celebrated river of the Amazons; in this enterprize he ſuffered many hardſhips, which were, however, more than requited by the inſtruction, which regions ſo remote, and ſo fruitful of the wonders of nature, afforded him. Here he compared the number of vibrations made by the ſame pendulum, which he had uſed at Paris, at Quito, and other places, and he found that for 100,000 vibrations at Paris, 98,770 were made by the ſame pendulum at the ſide of the Amazons, 98740 at Quito, and 98720 on Pinchincha. He publiſhed in the year 1745 an account of his travels, under the title of "Relation Abrégée d'un Voyage fait dans l'Interieur de l'Amerique Meridionale;" and in 1751, a "Journal du Voyage fait par Ordre du Roi a l'Equateur, avec un Supplement, en deux Parties." Condamine, after a ſhort reſidence at home, went to Italy, where he was honoured with the particular notice of the pope, who granted him a diſpenſation to marry his own niece. In 1762 he publiſhed ſome remarks on what he had ſeen in his tour through Italy. He then viſited England, and, among other intereſting objects, he became warmly attached to the new practice of inoculation for the ſmall-pox. On his return he publiſhed in two volumes "Memoires et Lettres ſur l'Inoculation." About this period he was elected member of the French Academy of Belles Lettres; he likewiſe received the ſame honour from ſeveral foreign learned ſocieties, as thoſe of London, Peterſburgh, Berlin, and Bologna. He died in February 1774, in conſequence of an operation for the hernia. "The acquiſitions of M. de la Condamine," ſays one of his biographers, "were more extenſive than profound; and he poſſeſſed rather an ardour for making reſearches on a variety of ſubjects, than patience completely to inveſtigate any." Nouv. Dict. Hiſt. Gen. Biog. See alſo the article Bouguer.

CONDANORE, in *Geography*, a town of Hindooſtan, in the country of Golconda; 15 coſſes E. of Adoni. N. lat. 15° 40′. E. long. 78°.

CONDAPILLY, a town of Hindooſtan, and capital of a circar of the ſame name, near the bay of Bengal; 142 miles S.E. of Hydrabad. N. lat. 16° 40′. E. long. 80° 4[illegible]′.

Condapilly, a circar of Hindooſtan, bounded on the N.E. by the circar of Ellore, on the S.E. by the bay of Bengal, on the S.W. by the river Kiſtnah, which divides it from Guntoor, and on the N.W. by the country of Golconda; about 60 miles long and 25 broad.

CONDATCHY, a bay of Ceylon in the Eaſt Indies, lying on the weſt ſide of the iſland, ſix miles ſouthward from Arippo, and about 12 miles from Manaar. N. lat. 8° 45′. E. long. 80°. In this bay all the boats are collected for the pearl-fiſhery. The bay forms nearly a half-moon; the beach which ſurrounds it is an extenſive ſandy waſte, with only a few miſerable huts ſcattered along the ſhore between the bay and the woods which ſkirt the beach. Such is the appearance which this bay preſents at moſt ſeaſons of the year; but during the fiſhery the ſcene is entirely reverſed. At that time the bay is crowded with ſmall veſſels, and the beach preſents an aſtoniſhing multitude of people from every quarter of India. The principal bank for the fiſhery is oppoſite to Condatchy, and lies out at ſea about 20 miles. See Pearl-*Fiſhery*.

CONDATE, in *Ancient Geography*, an appellation, probably of Celtic original, bearing relation to the idea of *Confluent*, and giving name to ſeveral towns, ſuch as follow.

Condate, or Redones, *Rennes*, a town of Armorica, the capital of the Redones, according to Ptolemy.—Alſo, *Montreau*, a town of Gaul, between Melodunum and Agedinium, which afterwards bore the name of Monaſteriolum.—Alſo, *Combe*, a place of Gaul between Noviomagus and Durocaſſes.—Alſo, *Cone*, a town of Gaul, between Nevirnum and Brivodurum.—Alſo, *Coignac*, a town of Gaul, between Mediolanum Santonum and Veſunna, according to the table of Peutinger.—Alſo, a place of the iſle of Albion, between Manucium or Mancheſter and Deva or Cheſter in, Antonine's Itinerary: generally placed at Congleton; but Mr. Horſley hath made it very probable that it was ſomewhere near Northwich.

CONDAT-en-Ferrieres, in *Geography*, a town of France, in the department of the Tarn; 10 miles N. of Murat.

CONDATOMAGUS, in *Ancient Geography*, a place of Gaul, marked in the Peutingerian table between Ségodunum and Luteva.

CONDAVIR, in *Geography*, a fortified place of Hindooſtan, and a principal poſt in the circar of Guntoor; ſtrongly ſituated on a mountain, eight coſſes to the weſt of Guntoor, and ten from the bank of the Kiſtnah. Not far from Condavir is Colore, a diamond mine on the ſouthern bank of the Kiſtnah. Condavir is diſtant S.E. from Hydrabad 131 miles; from Madras 276 miles; from Nagpour, S. 385 miles; and N.E. from Seringapatam 414 miles.

CONDE, Lewis I. *De Bourbon*, in *Biography*, was the ſon of Charles of Bourbon, duke of Vendome, and born in 1530. He diſtinguiſhed himſelf when very young at the battle of St. Quintin, and behaved with great gallantry till the death of Henry II., when he became a leader of the Huguenots. He was accuſed of having been the principal contriver of the conſpiracy of Amboiſe, but, in the preſence of the king, he vindicated his honour with all the intrepidity natural to him, and offered to maintain his innocence in ſingle combat againſt his accuſer. He was ſet at liberty, but engaging in another plot, he was condemned by his judges to have his head ſtruck off on a ſcaffold before the king's apartment. To the ſudden death of the ſovereign he was indebted for his freedom a ſecond time; he now openly put himſelf at the head of the Huguenots, and was admitted, with Admiral Coligny, to ſhare their full confidence. After many and very important inſtances of ſucceſs, he was wounded and taken priſoner in the battle of Dreux in 1562. At the battle of Jarnac 1569, he encountered the enemy with his arm in a ſcarf, and as he marched to the attack, the horſe of his brother-in-law reared and broke his leg; ſuperior however to this painful accident, he thus addreſſed his followers: "Nobility of France, know, that the prince of Condé, with an arm in a ſcarf, and broken leg, fears not to give battle, ſince you attend him." The village of Jarnac has been rendered memorable by the courage and conſtancy with which the Huguenots diſputed the day; but their leader Condé, exhauſted with fatigue, was ſurrounded and taken priſoner. Thoſe to whom he had yielded his ſword, had placed him at the foot of a tree, when Monteſquieu, captain of the duke of Anjou's guards, ſhot him dead, in cold blood, in revenge of a private quarrel. This ſavage, and truly infamous deed has affixed an indelible ſtain on the character of the duke of Anjou who was ſuppoſed to have authoriſed it. The body of Condé, thrown upon an aſs, was carried to the caſtle of Jarnac, and after being expoſed to the view of the victorious army, was delivered to the duke of Longueville, his brother-in-law, who cauſed it to be interred with thoſe of his anceſtors at Vendome. In his perſon, the prince of Condé was ungraceful and diminutive, yet his wit and vivacity rendered him a great favourite with the ladies. His amours gave occaſion to the concluſion that he engaged in the cauſe of the Huguenots more as a party-man, than as a religioniſt. This trait in his character was a foil to qualities the moſt ſplendid, and to virtues the moſt heroic. Of high and determined courage, he was formed to ſhine in camps as well as courts, and though his income was narrow, he diſplayed a magnificence of temper worthy his birth and ſtation. Nouv. Hiſt. Dict. Hiſt. de France.

Conde, Lewis II. *de Bourbon*, was born at Paris, Sept. 7, 1621. He was ſtyled Duke d'Enguien, and is known in hiſtory, under the appellation of the *great Condé*. He ſucceeded to the rank of prince by his father's death in 1646. In his infancy he was of an extremely delicate conſtitution, and was ſent into the country for the ſake of pure air. At a proper age the prince took upon himſelf the taſk of governor, and ſelected, as his aſſiſtant, in this important buſineſs, M. de la Bouſſieres, a private gentleman, upon whom he could depend for the moſt exact attention to the orders given him. Two jeſuits were likewiſe aſſigned to him as preceptors, who, with ſome officers of high rank and eminent probity and diſcretion, formed the houſhold of the young prince. With theſe attendants he went to Bourges, where he frequented the college of jeſuits, and became diſtinguiſhed in every branch of learning. His inclination was evidently turned towards the military art, and at the age of eighteen he made a campaign under Marſhal de la Meilleraye, that laid the foundation of that renown by which he was afterwards diſtinguiſhed as the greateſt general of his age. In the year 1643, he was entruſted with the command of the army oppoſed to the Spaniards who had invaded France; by a ſignal victory which he at that time gained, he was looked upon as the guardian genius of his country. So much coolneſs did he diſplay on this occaſion, that on the night preceding the battle, after he had made all the proper diſpoſitions, he ſlept ſo ſoundly that it was neceſſary to awaken him when it was time to begin the attack. He next formed the project of beſieging Thionville, and propoſed the ſcheme to the council of regency, who unwillingly conſented to it. The duke, contrary to expectation, carried it into execution with ſo much ſkill that the town ſoon ſurrendered. After this he was engaged in many combats in Germany, in one of which he threw his general's ſtaff into the enemies trenches, and led on a regiment, ſword in hand, to recover it. The victories of the duke d'Enguien, and his great and growing reputation rendered him an object of jealouſy to Cardinal Mazarin, who did every thing in his power to thwart his ambitious projects. The treachery of the cardinal, and the artifices of the leaders of the country party, excited cabals and troubles, but the duke d'Enguien, who, by the death of his father, had ſucceeded to the title of the prince of Condé, was careſſed by both parties. He at length took part with the court, though he felt it was an ungrateful taſk, and he protected the miniſter without feeling for him the leaſt eſteem.

The royal family left Paris privately, and went to St. Germains, upon which the parliament ſent deputies to learn from the queen the cauſes of her departure; but Mazarin diſmiſſed them contemptuouſly and without an anſwer. Exaſperated at this, the people made a common cauſe, and reſolved to defend themſelves againſt the power of the court. With about 8000 men, the prince of Condé formed a deſign of reducing above 500,000 intrenched behind walls. He had neither money nor magazines; nevertheleſs he triumphed over Paris, and this ſucceſs added not a little to the glory he had already attained. During the ſiege he conſtantly defeated the troops of the malecontents; he prevailed on the army that marched to their aſſiſtance under Turenne, to abandon their general; he ſtopped the progreſs of the duke de Longueville, who had cauſed an inſurrection in Normandy, and got the ſtart of the Spaniards who were advancing to give him battle. Peace was at length concluded, but Condé alone acquired glory by this war, and after the treaty was ſigned, the prince traverſed the ſtreets in his coach alone. All perſons of any rank paid their compliments to him, and he received a vote of thanks from the parliament. The people, however, were uneaſy at the king's abſence, and Condé at length brought the royal family to Paris amidſt the acclamations of the public: for this he was not recompenſed in the manner which he had anticipated; he accordingly united with the malecontents, was arreſted in 1650, and detained a year in priſon. Soon after his liberation, he broke out into open revolt, and a civil war followed which was attended with various ſucceſs. Condé exhibited great proweſs, and ſuſtained his military reputation through the whole of this unhappy warfare, though he was engaged in the ſervice of the Spaniards, the inveterate foes of his country, whom he had formerly obtained ſo much glory in reſiſting. At the peace of the Pyrenees in 1659, the re-eſtabliſhment of the prince of Condé was made a condition. In 1668, he contributed very materially to the conqueſt of Franche-Comté. He took part in the invaſion of Holland in the year 1672, and received a wound at the famous paſſage of the Rhine. He fought the bloody battle of Senef againſt the prince of Orange, in which he had three horſes killed under him, and was anxious to lead to a fourth attack, but as an officer obſerved, "No one but the prince of Condé was deſirous of fighting any longer." After the death of his great rival Turenne in 1675, Condé was ſent to check the progreſs of the imperial army, in Alſace, and diſplayed as much caution in this buſineſs, as he had before exhibited ardour and impetuoſity. By his conſummate prudence and judgment he forced the enemy to croſs the Rhine, and then, full of glory, he reſigned the military profeſſion, and retired to Chantilly, where he ſpent the remainder of his days in cultivating and patronizing letters and the fine arts, to which he had been always attached. During the laſt two years of his life his faculties had ſo much declined, that ſcarcely a trait was left of the *great Condé*. He died in 1686 at Fontainbleau, leaving behind him two ſons, by his wife, the niece of cardinal Richelieu. Nouv. Dict. Hiſt. Hume.

Conde', in *Geography*, a ſmall town of France, in the department of the Aiſne, and chief place of a canton in the diſtrict of Chateau-Thierry, 9 miles S.E. from Chateau-Thierry. The place contains 568 and the canton 9613 inhabitants. The territory includes 235 kiliometres and 27 communes.—Alſo, a fortified town of France, in the department of the North, on the confluence of the Haine and Scheldt, 9 miles N.E. from Valenciennes, known at preſent by the name of Nord Libre, which it took under the republican government of France. After a blockade of nearly four months, it ſurrendered to the Auſtrians on the 11th of July 1793, but was ſoon evacuated. It is the chief place of a canton in the diſtrict of Douay, and contains 5978 inhabitants. The territorial extent comprehends 87½ kiliometres, with 10 communes, and 13,621 inhabitants. Before the revolution of 1789, Condé was a principality from which the princes of Condé derived their title. There are in France ſeveral other ſmall towns of the name of Condé, which ſignifies confluence, from the Latin *condare*, *circumdare*, and means a place built on the ſpot where two rivers meet. See Condate.

Conde' *ſur Noireau*, a town of France, in the department of Calvados, on the river Nireau, or Noireau, chief place of a canton in the diſtrict of Vire, 24 miles S. from Caen, and 150 W. from Paris. The place contains 3030, and the canton 10,681 inhabitants. The territory includes 122½ kiliometres, and 12 communes. The inhabitants carry on a conſiderable trade in cloth, leather, and cutlery.

CONDE' *ſur Iton*, or CONDE' *l'Eveque*, a town of France, in the department of the Eure; 12 miles S.W. of Evreux.

CONDEAU, a town of France, in the department of the Orne, and diſtrict of Belleſme; 10 miles E. of Belleſme.

CONDECEDO, a cape or promontory of North America, in the province of Yucatan; 100 miles W. of Merida. N. lat. 20° 50'. W. long. 91° 27'.

CONDEMNATION, the act of paſſing, or pronouncing SENTENCE, or giving judgment againſt a man; whereby he is ſubjected to ſome penalty or PUNISHMENT; either in reſpect of fortune, reputation, or life.

CONDEMNATION *to the galleys*. See GALLEYS.

CONDEMNATION *of prizes* taken from the enemy. See PRIZE.

CONDENSATION (from *condenſate*, and condenſate from the Latin *condenſatus*), denotes the contraction of a given quantity of matter into a ſmaller ſpace, and in this ſenſe only the word condenſation ought to be uſed; however, in common language, the inſpiſſation, the thickening, or hardening of certain compound ſubſtances, in conſequence of the eſcape of ſome of their component ingredients, is frequently expreſſed by the ſame term; thus the juices of fruit, of plants, of meats, &c. are often ſaid to be condenſated over the fire. Compreſſion and condenſation (though ſometimes uſed the one for the other) differ in this; *viz.* that the former denotes a diminution of bulk, occaſioned by the application of external force; whereas the latter expreſſes the ſame effect, when produced without that external application, as is the caſe with moſt bodies in cooling. But the word condenſation has been more commonly uſed for denoting the converſion of vapour into water, or of vapours in general into liquids.

The particulars which might be noticed with reſpect to condenſation are, the quantity and rate of contraction in different bodies, the cauſes which produce it, and the limits of that contraction. Theſe particulars, however, will, with more propriety, be ſtated under the articles EXPANSION, THERMOMETER, and PYROMETER, which ſee.

Notwithſtanding the above-mentioned definition, it is to be remarked, that in every caſe of condenſation, or of the contraction of a body into a narrower ſpace, the effect is produced by the eſcape of ſomething; and in bodies, which ſeem to be the ſimpleſt in nature, the contraction which they undergo in cooling, is occaſioned by the eſcape of the caloric, which the preſent ſtate of philoſophical knowledge reckons amongſt the elementary ſubſtances. But the reverſe of this propoſition is not always true; *viz.* bodies are not always contracted in their dimenſions when the caloric eſcapes from them; and ſuch has been found to be the caſe with water, with iron, and with ſome other ſubſtances, in certain temperatures. This will be rendered more evident in the ſequel.

Moſt bodies are ſuſceptible of three ſucceſſive ſtates of exiſtence; namely, the ſolid, the liquid, and the elaſtic or vaporous; and all theſe are effected by the introduction of different doſes of caloric. During every one of thoſe ſtates, a different degree of condenſation is produced by the intermediate gradations of temperature; *viz.* ſuch as are not quite ſufficient to induce a different ſtate of exiſtence in the body concerned. Thus, a quantity of the vapour of water, which, at the temperature of 242° (Fahrenheit's thermometer), and under the mean gravity of the atmoſphere, occupies the ſpace of 3600 cubic inches; if it be gradually cooled until the temperature becomes equal to about 212°, its bulk will be contracted ſo as to occupy the half of the ſpace it did before, *viz.* about 1800 cubic inches. If the temperature be lowered below 212°, the vapour will be condenſed into liquid water, which will occupy the ſpace of not more than a ſingle cubic inch. If the cooling be continued, the water will be contracted in its bulk, but not very regularly (that is, the decrements of bulk will not be exactly proportional to the decrements of heat); until the temperature deſcends to about 42°. Below that degree, the water, inſtead of contracting its bulk, is expanded by further cooling; *viz.* by a further abſtraction of caloric. This is a very remarkable property of water, upon which ſome intereſting phenomena of nature are depending. The water, though expanding below the temperature of 42°, ſtill continues fluid as far as about the temperature of 32°; but below this laſt mentioned point, by farther cooling it becomes a ſolid; namely, ice; and in this ſtate water occupies a greater ſpace than it did in a liquid ſtate. (See CONGELATION.) Similar irregularities have been obſerved in the condenſations of ſeveral other bodies, both ſolid and fluid; and it is to be wiſhed that experiments capable of determining the laws of condenſation were inſtituted with all thoſe bodies which are at all ſuſceptible of the trial.

The cauſes of condenſation are by no means thoroughly underſtood. It may ſeem, at firſt ſight, ſufficient to ſay, that ſince caloric is an elementary ſubſtance, which is combined in various proportions with every other known body, the ſeparation of part of that element from the other bodies, naturally enables the particles of the latter to come cloſer to one another in virtue of their mutual attraction. But that this cannot be the ſole cauſe of the condenſation in its whole extent, is eaſily pointed out by the following queries. 1ſt. How are the particles of bodies diſpoſed, that they may be capable of approaching, or of receding from each other? 2dly, Why the degrees, or quantities, of condenſation are not always proportional to the degrees of caloric that are abſtracted from bodies? And, 3dly, Why clouds, fogs, miſts, &c. (which conſiſt of the vapour of water ſuſpended in the atmoſphere) are not always condenſed into liquid water below the temperature of 212°; which is actually the caſe in the atmoſphere?

It has for a long time been an opinion prevalent amongſt philoſophers, that the particles of bodies do not actually touch one another; for otherwiſe it ſeemed impoſſible to comprehend how a body could be expanded and condenſed. But the leaſt conſideration will eaſily ſuggeſt a variety of diſpoſitions of the particles, which, whilſt they actually touch one another, will readily admit of the dilatation and condenſation of the aggregate. Conceive, for inſtance (as profeſſor Prevoſt of Geneva juſtly obſerves), the particles to be elongated, and united at their extremities like the legs of a pair of compaſſes, and they may turn, with regard to this point of union, as a centre, and produce condenſations and dilatations of the whole apparent maſs of the body. A ſponge likewiſe will dilate in water without interrupting the continuity of its parts. One may alſo conceive the particles of bodies arranged in the form of rings; that is, many of them to be in abſolute contact, one with the next, and this with the following, &c., ſo as to form circular or oval rings. With this diſpoſition of particles, the dilatation and condenſation of the aggregate is nothing more than an alteration of the form of thoſe rings; *viz.* they become more like circles when the body is expanded, and more oblong when the body is condenſed; it having been demonſtrated by mathematicians, that the circle comprehends an ampler ſpace than any other figure of the ſame periphery. Though the general diſpoſition of the particles of a body is not known, yet a variety

riety of phenomena clearly indicate that they are not confuſedly placed; but that ſome arrangement, probably a peculiar one, for the particles of each different body, actually takes place; and to this peculiar arrangement ſome of the effects of dilatation and condenſation, at leaſt the irregularities of thoſe alterations, muſt undoubtedly be attributed. Thus the particles of water cryſtallize in freezing; that is, they diſpoſe themſelves with a peculiar regularity, ſomewhat reſembling the filaments of a feather. Theſe filaments of water form angles of about 60 degrees with a larger filament, which is, as it were, the ſtem of the feather; and to this cryſtallization the enlargement of the bulk of water in freezing is with propriety attributed. Such is the force with which the particles of water endeavour to arrange themſelves in that particular order, and of courſe to enlarge the bulk of the aggregate, that ſeveral aſtoniſhing effects are produced by their united efforts. Pieces of timber, ſtones, and other bodies, are burſt by the freezing of incloſed water. Even iron mortar-ſhells, ſuch as are uſed in war, filled with water, and accurately ſtopped, have been burſt by the freezing, and the conſequent enlargement of the incloſed water.

Since the enlargement of the bulk of water commences at about the temperature of 42°, which is 10 degrees above the point of melting ice, commonly called the *freezing point*, which is 32°, it is evident that the particles of water begin to arrange themſelves in a particular order long before the freezing takes place. And, by following the analogy, it may be ſuppoſed, that in every ſtate of exiſtence the particles of bodies have, more or leſs, a tendency to arrange themſelves in a certain order; to which tendency the irregularities in the condenſations of bodies are probably to be attributed.

The above-mentioned particulars, reſpecting the condenſation of water, muſt in great meaſure be underſtood to belong to a great variety of bodies; for all thoſe which have been ſubjected to deciſive experiments have been found to contract or to enlarge their bulk with irregularity, in ſome part at leaſt, if not throughout, the whole ſcale of heat.

The condenſation of vapour in the atmoſphere, which is not always accompanied with a proportionate degree of temperature, forms another difficulty, which the preſent ſtate of philoſophical knowledge is not entirely capable of explaining. We ſhall, however, briefly ſtate certain facts and certain conſiderations, which ought to be kept in view by thoſe who are willing to inveſtigate this intricate and intereſting ſubject. The converſion of water into vapour is attended with an increaſe of its capacity for containing heat, or caloric, and likewiſe with an increaſe of its capacity for containing electric fluid; ſo that if a quantity of water, held in an open and inſulated veſſel, be ſuffered to evaporate, the vapour will deprive the veſſel of part of its heat, and of part of its electric fluid: conſequently, the veſſel will be cooled and electrified negatively. Now that which philoſophers wiſh to aſcertain is, whether the influx of the caloric and of the electric fluid produces the evaporation, or the converſion of the water into vapour draws the caloric and the electric fluid from the contiguous bodies. In the firſt caſe, we ſee no reaſon why the caloric and the electric fluid ſhould ſpontaneouſly quit the contiguous bodies, and run to the water in order to force it to evaporate, becauſe both the water and the contiguous bodies are in an equilibrium; that is, in the ſame ſtate with reſpect to temperature as well as of electricity. In the ſecond caſe, if the influx of heat and of electricity does not force the water to evaporate, what other cauſe can produce that effect?

The ſame reaſoning which has been applied to the converſion of water into vapour, may, *mutatis mutandis*, be adapted to the contrary effect; *viz.* to the condenſation of vapour into water, it being equally difficult to comprehend how the vapour can remain in the elaſtic ſtate, that is, without being converted into water, at a temperature much lower than 212°, which in the atmoſphere is generally the caſe. There is one conſideration, however, which may throw ſome light upon this remarkable phenomenon; *viz.* that in order to depoſit the caloric and the electric fluid, which muſt neceſſarily take place in the condenſation of vapour, there muſt be a body or bodies ready to receive both. But in the atmoſphere, the only body which can receive them is the air, and it is well known, that air is a bad conductor of heat as well as of electricity. The laſt remark which we have to ſubjoin is, that it has been obſerved with ſeveral ſubſtances, and eſpecially with water, that though placed in a colder temperature, they do not part with their caloric ſo eaſily as it might be expected, and this is particularly the caſe when they are to undergo a change in their ſtate of exiſtence; thus water will ſometimes continue fluid when its temperature is 4 or 5 or even more degrees below 32°; though when once formed into ice, this will not melt at a temperature lower than 32°, and yet it will evaporate if expoſed to the air whilſt its temperature is many degrees below 32°.

CONDENSER, from *condenſe*, is an inſtrument capable of collecting, or of drawing into a ſmaller ſpace any ſcattered matter, or quality, or effect. In philoſophy and in mechanics, three different inſtruments have obtained the name of condenſers; *viz.* the *condenſer of air*, the *condenſer of electricity*, and the *condenſer of forces*.

The *condenſer of air*, in pneumatics, is a ſyringe, by means of which a conſiderable quantity of air may be forced into a veſſel fitted for the purpoſe. Fig. 1 and 2, *Plate* XIV. *Pneumatics*, repreſent two conſtructions of this ſort of condenſer, which differ but little from each other. They are generally made of braſs or of iron. A B, *fig* 1, repreſents a cylindrical tube, at moſt, two inches in diameter, and from 8 to 12 inches in length, or even longer. Its flat bottom B is perforated with a hole, on the outſide of which, a valve, (conſiſting of a piece of oil ſilk, or rather of leather, ſtretched over a ſmall flat piece of braſs), is adapted, ſo that if any air be forced from the inſide of the cylinder A B, that fluid will eaſily lift up the valve, and make its exit through the hole at B. But ſhould any ſuction take place within the cylinder A B, the air cannot poſſibly enter through the hole at B, becauſe the valve on the outſide prevents it by ſtopping that hole. The piſton *c d* fits the cavity of the cylinder A B pretty tightly, by means of leathers ſoaked in oil; and it may be moved up or down by the handle E which is faſtened to its rod. This piſton is perforated with a hole *c d*, the lower part of which is furniſhed with a valve *d*, which, when the piſton is drawn upwards, will permit the air to enter the lower cavity of the cylinder; but if the piſton be puſhed downwards, the air which is contained in the lower cavity of the cylinder, cannot paſs through the hole *c d*, on account of the valve at *d*; therefore it will come out through the hole at B. At the extremity of the cylinder, a braſs or iron cap F G is ſcrewed over the valve, allowing however a little room for its free motion. The end G of this cap is perforated quite through, and its outſide is formed into a ſcrew.

Fig. 2 repreſents a condenſing inſtrument ſimpler than the preceding, and ſuch indeed is at preſent moſtly uſed. Neither the cylinder nor the piſton of this inſtrument is furniſhed with any valve. There is a hole through the ſcrew at the bottom B of the cylinder, and a hole at C through its ſide, and at about two or three inches below its upper end; the piſton has no perforation.

When the condenſer, *fig.* 1, is ſcrewed into the aperture of a glaſs or metal veſſel, and the piſton is moved alternately up and down, it will be readily underſtood, that the air will be forced into the veſſel to which the condenſer is adapted; for when the piſton is pulled upwards, that is, towards A, the air cannot enter the cylinder through the hole at B, but it can eaſily paſs through the hole *c d*; and when the piſton is puſhed in, the air which is contained in the cavity of the cylinder, cannot go out of it through the hole *c d*, but it can paſs through the hole at B; hence it is forced to enter the veſſel to which the condenſer is applied. Thus by repeating the movements of the piſton, more and more air is condenſed into the veſſel, until the latter is burſt by the elaſticity of the condenſed air, or the ſame force puſhes ſo hard againſt the valve at B, that the ſtrength of the operator is no longer able to overcome it. The condenſer, *fig.* 2, is uſed exactly in the ſame manner; this, however, muſt be adapted to ſuch veſſels as are furniſhed with a valve within their aperture, which permits the entrance, but not the exit of the air. When the piſton of this condenſer is drawn towards C, a vacuum is formed in the lower part of the cylinder, until the lower part of the piſton is raiſed above the hole C; then the air ruſhes through that hole, and inſtantly fills the cavity, &c.

Theſe inſtruments are generally uſed for condenſing the air into the air-holders of wind-guns, of certain water fountains, and other machines. By this means, the air has ſometimes been condenſed to ſuch a degree, as to become ſix, eight, and even more times, denſer than common atmoſpherical air. The veſſel, in that caſe, is ſaid to contain reſpectively ſix, or eight, or a greater number of atmoſpheres.

In a variety of philoſophical experiments, ſubſtances are frequently placed in a glaſs veſſel in which air is condenſed, in order to obſerve its effects upon the encloſed ſubſtances. For this purpoſe, one of the above-mentioned condenſers is affixed to a frame and apparatus, as is repreſented in *fig.* 3.; and this apparatus, all together, is called a *condenſing engine*.

C D is a braſs condenſer, which is worked by applying the hand to the handle Z of the piſton, and by moving the latter alternately up and down, the air is forced through the braſs pipe D N F into the glaſs receiver A B. This receiver, which muſt be very thick and well annealed, is ſet with its ſmooth and flat edge upon the braſs plate of the machine, which is ſimilar to the plate of an air-pump. A thick piece of braſs L M, is applied in a ſimilar manner to the upper aperture of the glaſs receiver, and a ſlip-wire paſſes through a collar of leathers in this braſs piece. In order to prevent the lifting up of the braſs piece L M from over the glaſs veſſel, or the latter from the plate on the frame of the machine by the force of the condenſed air, two pillars of wood with a croſs piece G H, likewiſe of wood, are annexed, for the purpoſe of keeping down the glaſs veſſel, and the piece of braſs L M. The croſs piece G H is preſſed upon L M by means of the ſcrew-nuts on the pillars I, K. There is a gage E F, annexed to this machine, which indicates the condenſation of the air within the glaſs veſſel, and tube of communication. It conſiſts of a ſtrong and narrow glaſs tube, hermetically cloſed at E, and connected with the braſs tube of communication at F. A ſmall quantity of mercury fills up a ſhort part of the cavity about the middle of the tube, and the ſpace between the mercury and the cloſed end E of the tube, contains air of the uſual atmoſpherical denſity. It is by the contraction of this ſmall quantity of air, that the degree of condenſation in the glaſs receiver is indicated; for in proportion as the air is condenſed into the receiver, or tube of communication, &c., ſo the air between the mercury and the cloſed end of the gage becomes contracted more and more; and the quantity of that contraction is indicated by a ſcale annexed to the glaſs tube; for inſtance, if that air is, by working the machine, compreſſed into the half of the ſpace it occupied at firſt, it ſhews that the air within the receiver is as denſe again as it was before the working of the machine. If the air in the gage is compreſſed into a quarter of its original ſpace, the air within the receiver is ſhewn to be four times as denſe as it was before the working of the machine, and ſo forth; the condenſations in the glaſs receiver being inverſely as the ſpaces occupied by the air in the extremity E of the gage. Theſe degrees of condenſation are commonly expreſſed by ſaying, that *the receiver contains two, or three, or four, or more atmoſpheres,* when the air within it, is twice, or three times, or four times, or more times, denſer than the uſual air of the atmoſphere.

There are certain air-pumps, as thoſe of Smeaton, of Haas and others, the conſtruction of which renders them capable of being uſed for condenſing, as well as for exhauſting the air. See Air-pump. In certain forcing water pumps, in fire engines, and ſome other hydraulic machines, there is a veſſel, in which the air is condenſed by the action of the machine itſelf; the object of which is to produce a conſtant ſtream of water out of the engine, whilſt the piſton of it is moved up and down in the uſual way. This veſſel is called the *air veſſel,* and often the *condenſing-veſſel,* or ſimply the *condenſer.* See Pump, and Fire-*engine.*

The head of an alembic, wherein the vapours are condenſed into a liquid, has ſometimes been called the *condenſer* of the alembic.

Condenser *of Electricity.* This is an inſtrument capable of collecting, or of condenſing into a ſmall ſpace, ſuch quantities of weak and diffuſed electricity, as would otherwiſe remain unperceived, or be inſufficient to affect even the moſt ſenſible electrometer. It was originally invented by a very diſtinguiſhed philoſopher, Mr. Volta of Como, and is by himſelf deſcribed in the 72d vol. of the Philoſophical Tranſactions. But, ſince its original invention, this inſtrument has undergone ſeveral improvements and alterations, which we ſhall now deſcribe, together with their peculiar advantages and defects.

The action of electric atmoſpheres is the principle which ſuggeſted the conſtruction of this moſt uſeful electrical inſtrument. Though the nature of theſe atmoſpheres will be treated of in the article Electricity; it will, nevertheleſs, be neceſſary to give, in this place, ſome idea of their action, by means of an eaſy experiment, in order to render the principle upon which the electrical condenſer acts, manifeſt to the reader. Affix an electrometer of pith-balls to an inſulated metallic plate; that is, a plate of tin or braſs, or other metal, having a glaſs handle. Communicate ſome electricity to it, and obſerve the divergency of the electrometer. In this ſtate, bring the electrified plate near a conductor which is not inſulated, ſuch as the wall of a room or another metallic plate, and you will find that the electrometer collapſes in proportion as the electrified plate comes near to the uninſulated conductor. Remove the electrified plate, and the electrometer will diverge again, nearly as much as it did at firſt; which ſhews, that by the vicinity of the uninſulated conducting body, which could eaſily acquire the contrary electricity, the intenſity of the electricity in the electrified plate was diminiſhed; or, which is the ſame thing, that the capacity of that plate for containing electricity was increaſed. Hence, when an inſulated metallic plate is ſituated near another metallic plate not inſulated, the former will thereby be enabled to abſorb a much greater quantity of electricity than it otherwiſe would, from any ſource whatever; and if the electrified plate be removed from the other, then that abſorbed electricity will be manifeſted by the divergency of the electrometer, or even by affording a ſpark. It naturally follows, that according as the conductor which is oppoſed to the inſulated plate, is nearer to, or farther off, ſo the capacity of the plate will be increaſed more or leſs. Such an inſulated plate, placed upon an imperfectly inſulating, or an imperfectly conducting plane, for the purpoſe of collecting weak and ſcattered electricity, was called a *condenſer* by Mr. Volta. The reaſon of uſing an imperfectly conducting, or imperfectly inſulating plane, is, that when the inſulated condenſing plate is placed upon it, the electricity will not paſs from the latter to the former. In ſhort, the following particulars ſhould be attended to in the conſtruction of this, Mr. Volta's, condenſer. The metal plate ſhould be about ſix inches in diameter, with the edge well rounded, and furniſhed with a varniſhed glaſs handle. The inferior plane muſt be of a very imperfectly conducting nature, ſuch as dry marble, very dry and ſlightly varniſhed wood, a common piece of wood covered with oiled ſilk, or ſuch like ſubſtance; but be its ſubſtance what it may, its ſurface muſt be very ſmooth, and ſuch as to coincide as well as poſſible with the ſurface of the metal plate, *viz.* the receiving plate; on which account, if a marble ſlab be choſen for the inferior plane, it will be proper to fit the ſurface of the metal-receiving plate to that of the marble, by grinding one againſt the other.

The apparatus, conſiſting of the above deſcribed two planes, being properly conſtructed, lay the receiving plate upon the other plane, connect the former with an atmoſpherical conductor, not much elevated above a houſe, or with the vapour of boiling water, or, in ſhort, with any weak ſource of electricity, ſuch as could not be diſcovered by any other means, and after a certain time lift the receiving plate from over the other plane, holding it by the glaſs handle, and preſent it to an electrometer, which will be cauſed to diverge ſufficiently to aſcertain the preſence and the quality of the electricity. Sometimes the receiving plate will even be able to afford a ſpark. Yet, in ſeveral caſes, the receiving plate is electrified ſo ſlightly, as not to occaſion the divergency of the moſt delicate electrometer. A contrivance of Mr. Cavallo, which is deſcribed in his Treatiſe on Electricity, (fourth edition, vol. ii. p. 265) rendered this weak ſtate of electricity capable of affecting the electrometer in a very ſenſible degree. His deſcription of this contrivance is as follows:

" I naturally thought that, for the ſame reaſon which enabled the condenſing plate of Mr. Volta's apparatus, to manifeſt ſuch ſmall degrees of electricity as could not otherwiſe be obſerved, another ſmaller plate, or ſmall condenſing apparatus, might be employed to collect and to render ſenſible the weak electricity of the large metal plate. Accordingly, I conſtructed a ſmall plate of about the ſize of a ſhilling, having a glaſs handle covered with ſealing-wax; and when the large metal plate ſeemed to be electrified ſo weakly as not to affect an electrometer ſenſibly, I placed the ſmall plate upon the inferior plane, and touched it with the edge of the large plate; then, after removing the large plate, I took up the ſmall one from the plane, holding it by the extremity of the glaſs handle, and preſented it to the electrometer, which generally was ſo much affected by it as to diverge to its utmoſt limits.

" In this manner I have often obtained electricity, more than ſufficient to aſcertain its quality, from a ſingle ſtroke of the corner of an handkerchief; *viz.* the large plate being laid upon the proper plane, was ſtroked once with the handkerchief; then, being removed and preſented to an electrometer, it appeared not electrified; but by touching the ſmall plate with the edge of it, that ſmall plate acquired thereby electricity ſufficient to make an electrometer diverge."

With this condenſing apparatus Mr. Volta, and other philoſophers, made ſeveral diſcoveries; yet the uſe of it was not always attended with the deſired effect, which was principally owing to the changeable nature of the ſemiconducting plane, upon which the receiving plate was placed; it being difficult to obtain, and much more difficult to preſerve, ſuch plane in a middling or ſemiconducting ſtate; for ſometimes it would carry off the electricity from the ſuperimpoſed receiving plate, and at other times it was not of a conducting nature ſufficient to enable the upper plate to condenſe the electricity. It, likewiſe, often happened that this plane would acquire ſome electricity either in conſequence of the ſlighteſt friction, or by communication, which rendered the action of the upper plate quite equivocal. With a view to remove theſe inconveniences Mr. Cavallo contrived an inſtrument capable of anſwering the ſame purpoſe, but quite free from all the above-mentioned objections. The principle of this inſtrument is like that of Mr. Volta's condenſer; excepting that the receiving plate does not touch the other plane, though it comes very near it, and it likewiſe oppoſes another plane to the other ſide of the receiving plate. Thoſe planes are of metal, and by their not touching the receiving plate, enable the latter to act with certainty and without obſtruction. Upon this principle, *viz.* of the two plates not actually touching, but approaching one another very nearly, the preſent electrical condenſers are conſtructed, however they may have been varied in ſize, in name, and in ſhape. By the aid of theſe condenſers various important diſcoveries have been made in electricity, and eſpecially in that branch of it, which is called galvaniſm. The original deſcription of this inſtrument of Mr. Cavallo, is in the 78th. vol. of the Philoſophical Tranſactions, for the year 1788, from which we make the following extracts.

" The properties of this machine, which from its office may be called *a collector of electricity*, are firſt; that when connected with the atmoſphere, the rain, or in ſhort with any body which produces electricity ſlowly, or which contains that power in a very rarefied manner, it collects the electricity, and afterwards renders both the preſence and quality of it manifeſt by communicating it to an electrometer. Secondly, this collecting power, by increaſing the ſize of the inſtrument and eſpecially by uſing a ſecond or ſmaller inſtrument of the like ſort to collect the electricity from the former, may be augmented to any degree. Thirdly, it is conſtructed, managed, and preſerved with eaſe and certainty; and it never gives, nor can it give, an equivocal reſult, as I have proved experimentally, and as will appear by conſidering its conſtruction."

" The figures 4 and 5, *Plate*, II. *Electricity*, exhibit this inſtrument, *viz. fig.* 4 ſhews the inſtrument in the ſtate of collecting the electricity, and *fig.* 5 ſhews it in the ſtate in which the collected electricity is to be rendered manifeſt. An electrometer is annexed. The letters of reference indicate the ſame parts in both figures. A B C D is a flat tin plate, thirteen inches long and eight inches broad; to the two ſhorter ſides of which are ſoldered two tin tubes, A D and B C, which are open at both ends. D E and E F, are two glaſs ſticks covered with ſealing wax by means of heat, and not by diſſolving the ſealing wax in ſpirits. They are cemented in the lower apertures of the tin tubes, and alſo in the wooden bottom of the frame or machine, at E and F, ſo that the tin plate, ABCD, is ſupported by thoſe glaſs ſticks in a vertical poſition, and is exceedingly well inſulated. GHILKM and NOPV, are two frames of wood, which being faſtened to the bottom boards, by means of braſs hinges, may be placed ſo as to ſtand in an upright poſition and parallel to the tin plate, as ſhewn in *fig.* 4. or they may be opened, and laid upon the table which ſupports the inſtrument, as ſhewn in *fig.* 5. The inward ſurfaces of thoſe frames from their middle upwards are covered with gilt paper, X, Y; but it would be better to cover them with tin plates, hammered very flat. When the lateral frames ſtand ſtraight up, they do not touch the tin plate; but they ſtand at about one-fifth part of an inch aſunder. They are alſo a little ſhorter than the tin plate, in order that they may not touch the tin tubes, AD, BC. In the middle of the upper part of each lateral frame is a ſmall flat piece of wood, S and T, with a braſs hook; the uſe of which is to hold up the frames without the danger of their falling down when not required, and at the ſame time it prevents their coming nearer to the tin plate than the proper limits. It is evident that when the inſtrument ſtands as ſhewn in *fig.* 4, the gilt ſurface of the paper, X, Y, which covers the inſide of the lateral frames ſtands contiguous and parallel to the tin plate."

" When the inſtrument is to be uſed, it muſt be placed upon a window, a table, or other convenient ſupport, a bottle electrometer is placed near it, and is connected, by means of a wire, with one of the tin tubes, AD, BC; and by another conducting communication the tin plate muſt be connected with the electrified ſubſtance, the electricity of which is required to be collected on the plate, ABCD: thus, for inſtance, if it be required to collect the electricity of the rain, or of the air, the inſtrument being placed near a window, a long wire muſt be put with one extremity into the aperture, A or B, of one of the tin tubes, and with the other extremity projecting out of the window. If it be required to collect the electricity produced by evaporation, a ſmall tin pan, having a wire or foot of about ſix inches in length, muſt be put upon one of the tin tubes; ſo that the pan may ſtand about two or three inches above the inſtrument. A lighted coal is then put into the pan, and a few drops of water poured upon it, will produce the deſired effect."

"The quantity of electricity, which the tin plate, ABCD, is capable of collecting, principally depends on three circumſtances, *viz.* 1ſt. On the diſtance between the tin-plate and the conducting lateral ſurfaces: the ſmaller that diſtance is, the greater being the collecting power; 2dly. On the ſize of the inſtrument; and 3dly, On the quantity of electricity poſſeſſed by the body from which it muſt be collected or taken away."

" I need not expatiate on the principle upon which the action of this inſtrument depends; this being the ſame as that of the electrophorus of Mr. Volta's condenſer, and of many other electrical experiments; namely, that a body has a much greater capacity for holding electricity, when its ſurface is contiguous to a conductor which can eaſily acquire the contrary electricity, than when it ſtands not in that ſituation."

Though this original condenſer, which, by way of diſtinction, its inventor called a collector, anſwers the purpoſe for which it was intended perfectly well; yet for the common run of experiments, its ſize may be diſpenſed with, as it takes up too much room on the table of an electrician. On this account, not only the ſize of the inſtrument has been reduced, but its ſhape alſo has been varied according to the fancy of almoſt every philoſophical inſtrument maker. For the ſake of ſimplification in the condenſers which are at preſent in general uſe, one conducting plane only is oppoſed to the receiving plate, which anſwers the purpoſe ſufficiently well; for if the electricity collected by the receiving plate happens to be too weak to affect the electrometer, a ſmaller condenſer may be uſed, which will condenſe the electricity of the former, &c.

The forms of the condenſers that are moſtly uſed at preſent, are repreſented in *figs.* 6, 7, 8, and 9. *Fig.* 6 exhibits a vertical ſection of the condenſer conſtructed by Mr. John Read of Knights-bridge; *a a* is a circular flat plate of braſs, about eight inches in diameter, ſtanding inſulated, by means of the glaſs ſtick *f*, on the wooden foot *g*; *gh* is a hollow braſs cylinder, terminating in the hollow braſs cone *e c d h*; and to this cone the flat perforated braſs plate *b c c b* is affixed. The glaſs ſtick *f*, which, by means of a braſs ferril, is faſtened to the plate *a a*, has its lower extremity cemented in a cylindrical piece of wood, and this piece of wood is fixed in the bottom *g*. Now it will be eaſily perceived, by inſpecting the figure, that the hollow cylinder *hg* may be moved up or down by ſliding it upon the cylindrical piece of wood; and that, by ſo doing, the plate *bccb* may be brought near to, or removed from the plate *a a*, which is the receiving plate of this condenſer; *i* is a milled-head ſcrew, which ſerves to fix the plate *bb* at a proper diſtance from *a a*, where a ſtop is made for that purpoſe; when *i* is looſened, the plate *bb*, with *c h g*, which is all one piece, falls in the ſituation repreſented in the figure, and in that ſtate an electrometer is put in contact with the plate *a a*, in order to manifeſt the electricity which *a a* condenſed whilſt *b c c b* ſtood near it.

Fig. 7 repreſents a condenſer of another form, as made by Mr. Cuthbertſon. This ſort of condenſer is both ſimple in its conſtruction, and commodious in practice; *a b* is a braſs plate of about 8 inches in diameter (the inſtrument being ſhewn in profile), which is ſcrewed tight into the wooden head *c*, which is cemented on the glaſs ſtick *d*, and this is cemented with its lower extremity into the wooden ſtand *e e* of the inſtrument; *f i* is a ſimilar plate of braſs, faſtened to the braſs head and pillar *g i*, the lower part of which turns round a pin at *h*, ſo that it may either ſtand upright, or it may be inclined after the manner of the dotted repreſentation *h m*. It is almoſt ſuperfluous to add, that *a b* is the receiving plate of this condenſer. *Fig.* 8 ſhews a front view of a condenſer of this ſort, placed cloſe to a gold leaf electrometer, furniſhed with a ſmaller condenſer, *viz.* ſuch as is repreſented by itſelf in *fig.* 9. The ſmall condenſer, *fig.* 9, is ſimilar to the one repreſented in *fig.* 7; ſaving that in *fig.* 9 the receiving plate is affixed to the cap of a gold-leaf electrometer; ſo that this apparatus, *viz. fig.* 9, may be uſed by itſelf in moſt experiments; but in certain caſes it will be neceſſary to employ the condenſer *fig.* 7 firſt, and afterwards the electricity may be farther condenſed by means of the apparatus *fig.* 9, as ſhewn in *fig.* 8.

There is an inſtrument contrived by Mr. Wilſon, which he calls " a compound electrical inſtrument for condenſing and doubling." But as the conſtruction, as well as the principal uſe, of that inſtrument properly belongs to another claſs of electrical inſtruments, its deſcription will be found in another part of this work. See DOUBLER, and MULTIPLIER *of electricity*.

CONDENSER *of forces*. This name was given by Mr. R. Prony to a contrivance for obtaining the greateſt poſſible effect from a firſt mover, the energy of which is ſubject to augmentation or diminution within certain limits; and in general to vary at pleaſure the reſiſtance to which the effort of the firſt mover forms an equilibrium in any machine whatever, without changing any part of their conſtruction. (Bulletin of the Philomathic Society at Paris, No. 83.)

The general problem in mechanics, of which this condenſer is intended as a practical ſolution, is enunciated by Mr. Prony in the following terms:

"Any machine being conſtructed, to find, without making any change in the conſtruction, a means of tranſmitting to it the action of the firſt mover, by fulfilling the following conditions; *viz.*"

"1. That it may be poſſible at pleaſure, and with great ſpeed and facility, to vary the reſiſtance (againſt which the effort of the firſt mover muſt continually make an equilibrium) in limits of any required extent."

"2. That the reſiſtance, being once regulated, ſhall be rigorouſly conſtant until the moment when it is thought proper to increaſe or diminiſh the ſame."

"3. That in the moſt ſudden variations of which the effort of the firſt mover may be capable, the variation in velocity of the machine ſhall never undergo a ſolution of continuity."

Mr. Prony applies this ſolution of this problem to the dynamic effect of wind; but it will be eaſy to make the ſame general, when other firſt movers are uſed. *Fig.* 10 (*Plate* XVI. *Mechanics*) repreſents the plan, and *fig.* 11 the elevation of the machine. O O is the vertical arbor to which windmill-ſails are adapted; *e e e e* is an aſſemblage of carpentry, of which one of the radii, O *e*, bears a curved piece, *b d*, of iron or ſteel: vertical axes of rotation *a a a*, being placed round the axis OO; they alſo divide the circumference in which they are found, into equal parts. Each of theſe axes carries a curve *a f*, of iron, ſteel, or copper; ſo ſituated, that when the wind acts upon the ſails, the curve *b d* preſſes againſt one of the curves *a f*, and cauſes the vertical axis to which this laſt curve is affixed, to make a portion of a revolution. The curves *b d*, and *a f*, muſt be ſo diſpoſed, that when *b d* ceaſes to preſs on one of the curves *a f*, it ſhall at the ſame inſtant begin to act upon the following curve: the number of axes which are provided with theſe curves, muſt be determined by the particular circumſtances of each caſe, and it is alſo practicable to ſubſtitute, inſtead of *b d*, a portion of a toothed wheel having its centre in the axis OO, and to place portions of pinions inſtead of the curves *a f*; but the diſpoſitions repreſented in the figure are preferable. Each of the axes *a a a a* (which are all fitted up alike, though, for the ſake of clearneſs, only one of them has its apparatus repreſented in the drawing), carries upon it a drum or pulley, *t t r r*, on which is wound a cord that paſſes over a pulley *p*, and ſerves to ſupport a weight Q, by means of the lever F G, upon which this weight may be ſlided and faſtened at different diſtances from the point of motion G. The ſame axes, *a*, *a*, paſs through the pinions *q*, *q*, to which they are not fixed; but theſe pinions carry clicks or ratchets, which bear againſt *r r*; ſo that when the weight Q tends to riſe, the ratchet gives way, and no other effect is produced on the pinion *q q*, either by the motion of the axis or of the drum *t t r r*, excepting that which cauſes the aſcent of the weight *q q*. But the inſtant that the curve, or tooth *b d*, ceaſes to bear againſt one of the curves *a f*, after having cauſed the correſponding weight Q to riſe, that weight Q tends to re-deſcend, and then the toothed wheel *r r* acts againſt the ratchet, ſo that Q cannot deſcend without turning the pinion *q q* along with the drum *t t r r*. The pinion *q q* takes in the wheel *a b*, from the motion of which the uſeful effect of the machine immediately reſults; ſo that the effect of the deſcent of one of the weights Q is to ſolicit the wheel A B to motion, or to continue the motion in concurrence with all the other weights Q, which deſcend at the ſame time. This wheel, A B, carries beneath it oblique or bevelled teeth, G D, which take in a like wheel, C E, and cauſe the buckets at S to riſe.

From the preceding deſcription, it is ſeen that the machine being ſuppoſed to ſtart from a ſtate of repoſe, the wind will at firſt raiſe a number of weights, Q, ſufficient to put the machine into motion, and will continue to raiſe new weights, whilſt thoſe before raiſed are fallen, ſo that the motion once impreſſed will be continued.

Among the numerous advantages of this new mechaniſm, the following may be remarked:

1. No violent ſhock can take place in any part of the mechaniſm. 2. The uſeful effect being proportioned to the number of weights Q, which deſcend at the ſame time, this effect will increaſe in proportion as the wind becomes ſtronger, and cauſes the ſails to turn with greater velocity. 3. The weights, Q, being moveable along the levers F G, it will always be very eaſy to place them in ſuch a manner as to obtain that ratio of the effort of the firſt mover to the reſiſtance, which will produce the maximum of effect. 4. From this property it reſults, that advantage may be taken of the weakeſt breezes of wind, and to obtain a certain product in circumſtances under which all other windmills are in a ſtate of abſolute inactivity. This advantage is of great importance, particularly with regard to agriculture: the windmills employed for watering lands, are ſometimes inactive for ſeveral days, and this inconvenience is more particularly felt in times of drought. A machine capable of moving with the ſlighteſt breeze, muſt, therefore, offer the moſt valuable advantages.

CONDENSING OF WINES. See WINES.

CONDEON, in *Geography*, a town of France, in the department of the Charente; 25 miles S.E. of Saintes.

CONDER, a river of England, in the county of Lancaſter, which runs into the Iriſh ſea; 3 miles S. of Lancaſter.

CONDERCUM, in *Ancient Geography*, a ſtation of Britain on the line of Severus's wall at Benwell-hill, where the prefect of the firſt wing of the Aſti was placed. Not. Imp.

CONDERS, from the Fr. *Conduire*, to conduct, perſons who were employed in the fiſhery to give notice where ſhoals of herrings were paſſing; otherwiſe called *Balkers*; which ſee.

CONDESCENSION, in *Ethics*, denotes that ſpecies of benevolence, which deſignedly diſregards the ſuppoſed advantages of birth, title, or ſtation, in order to accommodate itſelf to the ſtate of an inferior, and diminiſh the reſtraint which the apparent diſtance is calculated to produce. Accordingly, it greatly enhances the value of every other ſpecies of benevolence.

CONDESUYOS DE AREQUIPA, in *Geography*, a juriſdiction of South America, under the biſhop of Arequipa, 30 leagues diſtant from that city; which extends about 30 leagues, with different temperatures of the air, and conſequently produces grains and fruits. In this juriſdiction is bred the wild cochineal, with which the Indians carry on a kind of trade with the provinces in which the woollen manufactures flouriſh. They firſt pulverize the cochineal by grinding it, and after mixing four ounces of it with twelve of violet maize, they form it into ſquare cakes called “mango,” each weighing four ounces, and ſell it for a dollar per pound. This country abounds in gold and ſilver mines, which have of late been much neglected.

CONDETTA, a town of France, in the department of the ſtraits of Calais, and diſtrict of Boulogne; 1½ league S. of Boulogne.

CONDICA, in *Ancient Geography*, a town of Aſia Minor, in Lycia, and in the country called Mylas, according to Ptolemy.

CONDIGNITY, Merit of, in *Theology*. See Merit.

CONDIGRAMMA, in *Ancient Geography*, a ſmall town of Aſia, on this ſide the mouth of the Indus, upon the coaſt of Gedroſia, according to Pliny.

CONDILLAC, Stephen Bonnet de, in *Biography*, a French metaphyſician, member of the Academy, and preceptor to the infant Don Ferdinand, prince of Parma, an honour to which he arrived from the high reputation that he had gained from his writings. The work by which he was firſt known was an “Eſſay on the Origin of Human Knowledge,” in 2 vols. publiſhed in 1746; in which he endeavours to develope the faculties of the mind, by giving a ſort of hiſtorical account of its ſeveral functions. In 1754, he gave to the world a “Treatiſe on Senſations,” in 2 vols. 12mo.: here he conſiders what would be the conceptions of a ſtatue, provided at firſt with a ſingle ſenſe, and ſucceſſively with the others; and hence he undertakes to account for the origin of memory, judgment, and the mental affections, and the gradual formation and correction of ſenſible ideas. In the courſe of the following year he publiſhed a “Treatiſe on Animals;” in which he refutes the notions of Deſcartes and Buffon concerning the merely mechanical nature of brutes, and ſhews in what manner their faculties are acquired. In 1776 his great work, entitled, “A Courſe of Study drawn up for the Inſtruction of the Prince of Parma,” was publiſhed in 16 vols. 12mo. As an introduction to theſe volumes, we have a diſcourſe on the different modes of communicating inſtruction; giving a decided preference to the gradual advance from particular facts up to general principles, inſtead of the contrary method. Metaphyſical lectures, logic, and the philoſophy of the human mind, are among the earlier parts of this courſe of ſtudy; and from theſe, as preliminary ſteps, he proceeds to the ſtudy of hiſtory, of which he has given an ample and well-arranged abridgment, in eleven volumes. As an appendix, is added a volume conſiſting chiefly of political reflections. This ingenious writer publiſhed alſo a ſmall work, entitled, “Commerce and Government conſidered relatively to each other.” In all his works he exhibits an extenſive knowledge, a mind well imbued with the principles of humanity, and with the moſt liberal notions of government. He died in the year 1780, highly reſpected by his countrymen, and characterized for the ſoundneſs of his judgment, for the clearneſs of his ideas on every ſubject which he undertook to diſcuſs, and for his general knowledge in almoſt every department of literature. Nouv. Dict. Hiſt.

CONDITION, in the *Civil Law*, an article of a treaty, or contract; or a clauſe, charge, or obligation, ſtipulated in a contract, or added in a donation, legacy, teſtament, &c.

The donee does not loſe his donative, if it be charged with any diſhoneſt or impoſſible conditions. Lawyers diſtinguiſh three kinds of conditions, under which a legacy or donation may be made: theſe are the *caſual*, which depends merely on chance; the *poteſtative*, which is abſolutely in our power; and the *mixed condition*, which is both caſual and poteſtative together.

Condition, in *Common Law*, is a manner, quality, or reſtriction, annexed to an act; qualifying or ſuſpending the ſame; and making it precarious and uncertain, whether or not it ſhall take effect.

Accordingly, it is defined to be what is referred to an uncertain chance, which may or may not happen. Or, condition is a modus, or quality, annexed by him that hath eſtate, intereſt, or right to the land, &c. whereby an eſtate, &c. may be either created, defeated, or enlarged upon an uncertain event: and it differs from a *limitation* (which ſee), which marks the bounds or compaſs of an eſtate, or the time how long the eſtate ſhall continue.

A condition is alſo conſidered as one of the terms upon which a grant may be made; and in this ſenſe a *condition in a deed* is a clauſe of contingency, on the happening of which the eſtate granted may be defeated; as “provided always, that if the mortgager ſhall pay the mortgagee 500*l.* upon ſuch a day, the whole eſtate granted ſhall determine;” and the like.

Of conditions there are various kinds; *viz.* conditions in deed or expreſs, and in law or implied; conditions precedent and ſubſequent; conditions inherent, and collateral, &c.

Condition *in deed*, or *expreſs*, is annexed by expreſs words to the feoffment, leaſe, or grant, either in writing, or without. As, if a man make a leaſe of lands to another, reſerving a rent to be paid at ſuch a feaſt; *upon condition*, if the leſſee fail in payment, it ſhall be lawful for the leſſor to re-enter.

Condition *implied*, called alſo *condition in law*, is when a man grants to another the office of a ſteward, bailiff, keeper of a park, &c. for life: though there be no condition expreſſed in the grant, yet the law makes one covertly; which is, that if the grantee do not juſtly execute all things belonging to the office, it ſhall be lawful for the grantor to diſcharge him.

Condition *precedent*, is when a leaſe or eſtate is granted to a perſon for life, upon condition of the payment of a certain ſum by the leſſee to the leſſor at a certain day, when he ſhall have fee-ſimple: in this caſe the condition precedes the eſtate in fee, and on performance gains the fee ſimple.

Condition *ſubſequent*, is when a man grants to another his manor in fee, upon condition that the grantee ſhall pay to him a certain ſum on ſuch a day, or that his eſtate ſhall ceaſe: ſo that here the condition follows the eſtate, and the performance preſerves it. From theſe definitions it appears, that a *condition precedent* gets or gains the thing or eſtate made upon condition by the performance of it; and that a *condition ſubſequent* keeps and continues the eſtate by the performance of the condition. If one agree with another to do ſuch an act, and for the doing of it the other ſhall pay ſo much money; here the doing of the act is a *condition precedent* to the payment of the money, and the party ſhall not be compelled to pay till the act is done; but when a day is appointed for the payment of money, which day happens before the thing contracted for can be performed, there the money may be recovered before the thing is done; for here it appears, that the party did not intend to make the performance of the thing a *condition precedent*. For a further account of theſe conditions, ſee the article Estate *upon condition*. There are other *conditions*, beſides thoſe already mentioned: ſuch are conditions *inherent*, being ſuch as deſcend to the heir with the land granted; and *collateral condition*, being that which is annexed to any collateral act. Conditions are likewiſe *affirmative*, which conſiſt of doing; *negative*, which conſiſt of not doing:

ſome are ſaid to be *reſtrictive*, for not doing a thing, and ſome *compulſory*, as that the leſſee ſhall pay the rent, &c. Some conditions are *ſingle*, to do one thing only; ſome *copulative*, to do divers things; and others *disjunctive*, where one thing of ſeveral is required to be done. Co. Litt. 201.

CONDITIONS *in reſtraint of Marriage*, have not been generally favoured, as contrary to ſound policy; but where a legacy hath been given over to another, the condition has been held valid; and it ſeems, that ſuch conditions as only reaſonably reſtrain children from imprudent marriage will be always ſupported:—that is, when they operate only as particular, not as univerſal reſtrictions. Where a legacy is given on conſideration that the legatee ſhould not marry without conſent, and there is no deviſe over, the condition is void. 4 Burr. 2055. Com. Rep. 739. The rule of the eccleſiaſtical law is, that where a portion is given in conſideration that the daughter ſhould never marry, the condition is void. As the intent of the teſtator chiefly governs in wills, ſuch conſtruction is always made of the words, as will beſt ſupport his intent; and therefore theſe words *ad faciendum*, *faciendo*, *ea intentione*, *ad effectum*, &c. in a will create a condition. Co. Litt. 204. *a*. A grant to one to the intent he ſhall do ſo and ſo, is no condition, but a truſt and confidence. Some words in a leaſe do not make a condition but a covenant, upon which the leſſor may bring his action. A covenant not to grant, ſell, &c. may be a condition; and covenant, that, paying the rent, the leſſor ſhall enjoy the land, is conditional. 2 Danv. 2. 6. Where words are indefinite, and proper to defeat an eſtate, they ſhall be taken to have the force of a condition. Palm. 503. For the performance of conditions and relief againſt the breach of them, ſee Jacob's Dict. by Tomlins, art. CONDITION.

CONDITION of a *Bond*. See BOND.

CONDITION *without which*, *ſine qua non*, is uſed in *Philoſophy*, in ſpeaking of ſome accident or circumſtance, which is not eſſential to the thing, but is yet neceſſary to its production. Thus, light is a condition without which a man cannot ſee objects, though he have good eyes; and thus fire, though conſidered in itſelf, may burn without wood; yet is its preſence a condition without which the wood cannot be burnt.

CONDITION, *applied to Horſes*, is uſed to ſignify that a horſe is well fed and of good appearance; it alſo has another ſignification, that of his being brought by ſuitable treatment into a ſtate of body, that gives him the fulleſt uſe of all his faculties in performing any very difficult or arduous exertion or exerciſe, as for hunting, racing, trotting, or the arts of the manege.

A horſe that is moderately fat may be ſaid to be in good condition, and ſo he is for ſale, or for ſlow heavy draught-ſervice; but ſuch a one would be totally out of condition for any of the above exerciſes. To condition a horſe for theſe a proper ſhare of clean nouriſhing food and exerciſe is neceſſary, as much only as would confer the utmoſt point of ſtrength and power, without adding any uſeleſs incumbrance of matter to the body that might clog the freedom of reſpiration, or increaſe the weight and bulk of the animal, and impede rather than aſſiſt the functions of the organs, viſcera, and limbs. This art, if properly underſtood, ſhould impart the greateſt facility of wind, and join to lightneſs of the body the greateſt poſſible elaſticity and ſtrength of the muſcular ſyſtem. Such is properly the art of *training*, to which we refer the reader, and in which, though great things have been done, more wonderful might be yet effected; if to a well-founded view of nature in theſe animals was added all that conſummate and well-placed art could bring to her aſſiſtance, for nature we are led to believe has been but too often thwarted inſtead of aſſiſted by the arts of ſtable-men, jockies, and ſmiths.

Though mere practice alone will teach much, yet when combined with a juſt ſyſtem or knowledge of cauſe and effect, the art, whatever it be, may be carried to much higher perfection than it can otherwiſe.

For the preſent, we only treat of condition in horſes, for the common and ordinary purpoſes to which they are applied.

To ſtable ſervants is left in general the phyſicking, dieting, and conditioning the horſe; and a myſtery has often, with the ignorant, more charms than the clear face of truth herſelf. The effects of drugs upon horſes are very little known, perhaps, except the purgative effect of aloes, and the diuretic effect of ſoaps and turpentines, and neutral ſalts; we have ſcarcely any medicine whoſe effects we really know upon the horſe, or that appears at preſent likely to be known, yet are grooms ever phyſicking their horſes with ſome drugs or other; good clean food in plenty, dry lofty ſtables, gentle exerciſe, and attention to the ſkin in keeping it clean, will bring almoſt any horſe that is out of condition into condition, unleſs there be ſome lurking diſeaſe; yet nauſeous drugs are added to their food, and they are pleaſed to fancy that the effects they experience reſult from theſe, though it is more probable, as far as they go, and in the uncertain and often idle doſes in which they are exhibited, that they prevent, rather than aſſiſt, the purpoſe they have in view, and rather diſturb their digeſtion, and weaken the ſtomach, than aſſiſt it; or more certainly render nauſeous and loathſome the food they could otherwiſe reliſh; antimony, nitre, brimſtone, elecampane root, &c. are among their ſecrets for this purpoſe. Antimony is, however, believed, by better judges than theſe, to affect the ſkin of the horſe, and promote perſpiration; this it may poſſibly do. We may, however, juſt remark, that where it affects the ſkin, it has the power of affecting the ſtomach; but with pigs, horſes, and a variety of other animals, it does not affect the one, and one ſhould doubt whether, in theſe caſes, it would affect the other; for in no quantity whatever, and we have given 4 oz. at a doſe, does it appear to affect the ſtomach; nitre in larger quantities than they are uſed to give, will increaſe the urine; but how this promotes condition, we have not yet been informed. The reſt of their noſtrums are obviouſly inert, at leaſt their actual effects, when puſhed, till they become externally ſenſible, have never been exhibited; and unleſs they are, we cannot know them. There is, however, another, and a more certain purpoſe anſwered, in the adminiſtration of their drugs, and to which the ſcience of medicine, in ignorant hands, is but too frequently made ſubſervient; and without which, we believe, there would not be ſo much anxiety about the adminiſtration of them.

There is one inſtance, however, in which we rejoice to have it in our power to concur with theſe men in the uſe of medicine, and that is on horſes coming from graſs; this appears to be a really uſeful practice, and we think, from ſufficient experience, we can vouch for the fact, though to give medicines without a direct indication for their uſe, would at firſt appear repugnant to reaſon, yet it is uſual with grooms to give one, two, or more doſes of phyſic, on the horſe being brought from graſs "to clear him out," as they ſay; but if ſuch were the only effect, there would be no occaſion for it, as the graſs would very naturally come away from him without its good effects: we ſhall give a different account of the ſudden change of life, from green relaxing watery food, as graſs, to dry hay and ſtimulating corn; from free open air and nightly dews, and all kinds of weather, to a cloſe, low, foul, and crowded ſtable, the air of which is heated to an exceſs, and filled with ſtimulating exhalations from the dung; the water which had been received in quantities unreſtrained, is now portioned out (though it is really more neceſſary) in miſerable pittances. The body, before expoſed, is wrapped in rugs and cloths, and the whole ſyſtem becomes heated and inflamed by the ſudden changes, inflammatory complaints of the lungs, eyes, palate, throat, inteſtines and feet, are produced; and it is therefore uſeful on this account, in keeping off theſe attacks, to lower the habit by phyſic, after the horſe has been a few days in the ſtable, and to paſs by ſlow degrees to the exceſſive uſe of theſe vigorous ſtimuli. Dealers like to mix carrots with their corn, and bleed occaſionally, and give bran maſhes, which has the ſame effect.

In turning out alſo, grooms are again for phyſicking their horſes, and under the ſame pretence of clearing them out, and preparing them for graſs. They will, however, be ſufficiently lowered and reduced by the graſs itſelf, without any additional reduction by phyſic. It may not be an uſeleſs precaution, however, to withdraw by degrees the uſe of corn, previous to turning out, and the removing all ſort of clothing, to give water in greater abundance, that the change may not be too ſuddenly felt, and bring on broken wind, farcy, and the diſeaſes induced by too great debility.

In Arabia, where the fineſt horſes of the world are produced, a late traveller in thoſe countries, (Mr. Barker), informs us of the extraordinary ſimplicity of their treatment of them. They do not uſe any inſtrument for dreſſing or cleaning them. They merely faſten them to a picket by the leg or a halter, to give them their food, which, during the ſpring, conſiſts only of graſs; and when the earth no longer produces that nutriment, they ſupply the want by camel's milk, which, he ſays, is moſt aſſuredly preferable to any kind of grain.

Beans, malt, oats, clover, hay, and meadow hay, are the general food of horſes in England, and are ſuppoſed to be ſtimulant or invigorating to the ſyſtem of the horſe, in the order in which we have placed them. Barley was the ancient food for horſes, the diſcovery of oats being comparatively of modern date.

In the north of Holland, they feed their horſes principally on the black ſour bread called bumpernickle, made of buck wheat, and there it is eaten alſo by a large ſhare of the inhabitants; for this purpoſe, they alight from their vehicles, and, without taking the horſes out of their hempen traces, cut it in ſlices, and give them to eat. We obſerved that they appeared relaxed by it, but apparently without much debilitating them, as they ſeemed to do their work very well.

In the "Muſeum Ruſticum" is a propoſition founded apparently on actual experiment of feeding horſes on carrots, vol. i. p. 333. The following remarks we think worth recording from that communication: "I have a couple of hunters which I value as being very good horſes, and theſe I feed in the ſeaſon with very little elſe beſides carrots well cleaned from the dirt, and loaves made of the meal of barley and oats, mixed ſometimes with a ſmall admixture of coarſe but good wheat meal; and if they require to be looſened in their bodies, I now and then give them ſome bran. As to hay, they eat at this ſeaſon but little of it, of oats none at all, yet they go through their work to admiration."

Furze or whinns has been found uſeful food in ſuſtaining horſes, after it has been bruiſed, and the ſpines or prickles cruſhed; this ſome horſes will naturally do with their feet. Dr. Darwin relates, that on one particular common, all the horſes do it; and that freſh comers ſtarve, till by imitation they learn this practice, as the common, in other reſpects, is very barren. In Wales, mills, we underſtand, have been uſed for cruſhing the furze for cattle.

Saintfoin is a food that horſes are very fond of; but as they eat it very greedily, too much ſhould not be allowed at once for fear of indigeſtion, and it ſerves better for horſes of ſlow draught, being a coarſe heavy food.

Salt is imagined an uſeful addition to the food of horſes, Salt marſhes have often a preference given them over other ground for horſes and cattle; whether it is the ſalt that in itſelf operates beneficially, or whether the herbage itſelf is altered by it, and is rendered more ſalutary to the cattle, is not known. The ſame correſpondent, in the Muſeum Ruſticum, ſays that ſalt in ſubſtance is abundantly diſtributed in the mountains by the Swiſs, for the uſe of their cattle and horſes, who become exceſſively fond of it, and more healthy in conſequence; it is conceived to be an antidote to worms and other formations in the body, and the long continued uſe of it to cure them when formed, vol. i. p. 99. Horſes, he obſerves, are fond of it with their oats.

Horſes when at liberty are almoſt ever feeding, therefore long faſting muſt be injurious to the ſtomach, and ſhould be as much as poſſible avoided; they would alſo naturally, there is reaſon to believe, feed principally during the night, and ſleep during the day; their ſleep, however, is hardly ever, in health, profound and faſt, but is a ſtate of watchful dozing.

Horſes are naturally gregarious, and though they will do very well alone, company, where there is an opportunity for it, is preferable for their health. The ſtable ſhould be lofty, ſo as not to confine an atmoſphere about them, loaded with exhalations from their own bodies and their dung: the loftineſs alone of the ſtable is their beſt airing; all partial draughts from doors, windows, or holes into the loft, as far as they affect them, are injurious; for we have often remarked, that though they bear the coldeſt weather of our ſeaſons when turned out, yet they eaſily take cold from partial drafts in ſtables, inſomuch, that perſons not attentive to theſe effects would hardly believe their facility.

In cleaning the ſkin, the curry-comb is conſidered as a neceſſary implement. In warmer climates, where the ſcurf comes away more freely, this inſtrument is not ſo much uſed; and here it is often uſed to horſes whoſe ſkins are particularly thin and ſenſible, yet no difference is made; and though the animal expreſſes, in every way he can, the exceſſive torture it occaſions, yet it is perſiſted in, and violence is often had recourſe to, to enforce it, and horſes are thus rendered vicious and untractable. Where this is found to be the caſe, it would ſave much trouble and inconvenience to uſe a milder kind of comb, or to lay it aſide altogether, and uſe a ſtiff bruſh made for the purpoſe. It is more eaſy by violence and puniſhment to create vice, than to overcome a natural diſlike by it.

Warm clothing, on account of its keeping up a free perſpiration, tends to render the ſkin cleaner, makes the coat lie better, and have a more gloſſy appearance, and ſaves trouble. It is too often, however, carried to an exceſs, and two or three hot rugs keep the horſe in a perpetual fever; and as they are all taken off, when he is moſt expoſed, on going out, the ſudden check given to the perſpiration by the elements without, lays the foundation of diſeaſe, and occaſions inflammations of the lungs, catarrhs, and coughs, that might as well be avoided by more moderate and judicious proceedings, beſides the weakening effects of ſuch violent perſpirations.

There is a principle in feeding them that ought not to be overlooked; which is, that good food may be carried too far, till, inſtead of condition, it produces fever and diſeaſe, and deſtroys the condition it is meant to promote. Green vegetable food fills out the body; and from its weight and watery nature weighs down the abdomen, giving an unſightly appearance. Some horſes, however, can work with this, that more ſtimulating food does not ſuit ſo well. The dry diet braces the ſyſtem, and draws up the abdomen. The food is longer retained in the large inteſtines, which occaſions the flanks to appear full and rounded, and greatly adds to the beauty of the horſe's make in theſe parts.

Some horſes we have noticed have voracious appetites, and devour great abundance of corn, and whatever is ſet before them, yet always look meagre and out of condition. When this has been the caſe, we have been led to believe that by too much food, and of too heating a quality, the ſtomach and inteſtines have been paralyzed, and loſt their powers of forming chyle, or abſorbing it. Turning out to the green paſture will often bring them into condition, and they fall off again in the ſtable. Horſes of ſmall make and fiery temper are, we have thought, more particularly ſubject to this diſeaſe.

Water, like the food, ſhould be given often, and not in too large quantities: ſtinting horſes is a dangerous cuſtom; it induces them, where there is an opportunity to take enough at once, to break their wind, or otherwiſe injure themſelves. See art. *Broken* Wind.

The ſkin, to look well and healthy, ſhould be ſmooth, ſupple, and eaſy upon the muſcles, free from knots, and by no means tight about the ribs. The hair clean, bright, and gloſſy, lying to the ſkin, and not diſtorted, or turning away from it, or twiſted, dry, or thready. The effects of cold air on the ſkin of the horſe, in ſetting up the hair, is well known to the grooms, who cautiouſly avoid it.

Exerciſe to animals by nature born to be fleet, is particularly neceſſary; beſides the good it does in moving and forwarding all the ſecretions and excretions. This ſhould be gentle or vigorous, proportioned to the ſtrength and ſtate of the horſe, without diſtreſſing or too much fatiguing him. A gentle perſpiration looſens the ſcurf, and makes him clean better.

The hide ſoon gets foul, and a groom that has much pride in the appearance of his horſe, is almoſt inceſſantly currying, bruſhing, and hard rubbing the coat.

It is a cuſtomary thing with the dealers in horſes, in forming a judgment of the actual ſtate of the horſe, and whether his condition will admit of farther advancement, to handle the creſt, or upper part of the neck which carries the mane: if this be lax in the hand, and eaſily pliant, it is preſumed the condition may be carried farther; if, on the contrary, this part has a ſtiff tenſe feel, it is conſidered that farther improvement is not to be expected. Among the acknowledged indications alſo of poverty and good condition, is the poor mark in the buttock, that is the channel, or depreſſion running down the buttock, at its poſterior part; being a depreſſion formed between the muſcles. If this channel is very viſible and deep, the horſe is out of condition; if obliterated, ſo as to be hardly viſible, he is conſidered in condition.

Blood horſes are more eaſily cleaned than the common kind of horſes; their coat is not ſo thick, it does not retain the perſpiration ſo much, and the hair takes a better poliſh; which makes an experienced groom always prefer them

Too great excitement from the food, and undue fever, may be known by the heat of the mouth, the fulneſs of the veſſels of the eyes, the ſtrength of the pulſe, and diminiſhed appetite; the ſkin alſo, and extremities, are found too hot or too cold, languor and weakneſs follow: the remedies are before ſtated.

CONDITIONAL, ſomething not abſolute, but ſubject to limitation.

Conditional legacies are not due till the conditions are accompliſhed.

The Arminian divines maintain, that all the decrees of God, relating to the ſalvation and damnation of man, are truly conditional; and the Calviniſts, that they are all abſolute. See Arminian, &c.

Conditional *conjunctions*, in *Grammar*, are thoſe which ſerve to make propoſitions conditional. As, *if*, *unleſs*, *provided that*, *in caſe of*, &c.

Mr. Horne Tooke, in his "ΕΠΕΑ ΠΤΕΡΟΕΝΤΑ, or Diverſions of Purley," &c. has given us a new ſyſtem, with regard to theſe conditionals, as well as other conjunctions. Our conjunction *if*, he ſays, is merely a verb; being the imperative of the Gothic and Anglo-Saxon verb ᏀIꝻĀN, Ᵹiꝼan. And in thoſe languages, as well as in the Engliſh formerly, this ſuppoſed conjunction was pronounced and written as the common imperative, purely ᏀIꝻ, Ᵹiꝼ, *gif*. In proof of the truth of this etymology of the word *if*, the author obſerves, that whenever the datum upon which any concluſion depends, is a ſentence, the article *that*, if not expreſſed, is always underſtood, and may be inſerted after *if*. But the article *that* is not underſtood, and cannot be inſerted after *if*, where the datum is not a ſentence, but ſome noun governed by the verb *if* or *give*. This, he ſays, will hold univerſally, not only with *if*; but with many other ſuppoſed conjunctions, ſuch as, *but that*, *unleſs that*, *though that*, *leſt that*, &c. which are really verbs, put in this manner before the article *that*. *An*, now indeed obſolete, but formerly often uſed to ſupply the place of *if*, is alſo a verb; being nothing elſe but the imperative of the Anglo-Saxon verb Ānan, which likewiſe means to *give* or *grant*. If recourſe ſhould be had for confuting the author's opinion to the conditionals of the Greek and Latin, and Iriſh, the French, Italian, Spaniſh, Portugueſe, and many other languages, he obviates the objection by alleging, that thoſe words which are called conditional conjunctions, are to be accounted for in all languages in the ſame manner as he has accounted for *if* and *an*. Not that they muſt all mean preciſely as theſe two do—*give* and *grant*; but ſome word equivalent: ſuch as, *be it*, *ſuppoſe*, *allow*, *permit*, *put*, *ſuffer*, &c.; which meaning is to be ſought for from the particular etymology of each reſpective language. "To put this matter of doubt," he ſays, "I mean to diſcard all ſuppoſed myſtery, not only about theſe *conditionals*, but about all thoſe words alſo which Mr. Harris and others diſtinguiſh from prepoſitions, and call *conjunctions* of ſentences. I deny them to be a ſeparate ſort of words or part of ſpeech by themſelves. For they have not a ſeparate *manner* of *ſignification*; although they are not devoid of ſignification. And the particular ſignification of each muſt be ſought for amongſt the other parts of ſpeech, by the help of the particular etymology of each reſpective language. By ſuch means alone can we clear away the obſcurity and errors in which grammaiaurs and philoſophers have been involved by the corruption of ſome common words, and the uſeful abbreviations of conſtruction." See Conjunction.

Conditional *propoſitions*, in *Logic*, are ſuch as conſiſt of two parts, connected together by a conditional particle. Of theſe, the firſt, wherein the condition lies, is called the *antecedent*, and the other the *conſequent*.

Thus, "if the ſoul be ſpiritual, it is immortal;" is a conditional propoſition, wherein, "if the ſoul, &c." is the antecedent, and "is immortal" the conſequent.

The truth of theſe propoſitions depends on the truth of the connection of them, and they may be properly denied or contradicted when the negation affects their conjunctive particles. See PROPOSITION.

CONDITIONAL *ſyllogiſm*, is that whoſe major or minor, or both, are conditional propoſitions: *e. gr.* "If there be a God, the world is governed by Providence; but there is a God, therefore the world is governed by Providence." See SYLLOGISM.

CONDITIONAL *eſtate*, *fees*, *pardons*, and *reſignations*. See the ſubſtantives.

CONDITIONALS, *ſcience of*, i. e. of *conditional truths*, imports that knowledge which God has of things, conſidered, not according to their eſſence, their nature, or their real exiſtence; but under a certain ſuppoſition, which imports a condition never to be accompliſhed.

Some of the ſchoolmen deny, that God has the knowledge of conditionals: the Thomiſts maintain, that God's knowlege of conditionals depends on a predetermining decree; others deny it.

F. Daniel obſerves, that the truths which compoſe the knowledge of conditionals, being very different from thoſe which compoſe the knowledge of intuition, and that of underſtanding; a third claſs muſt be added, and the knowledge of God be divided into *intuitive*, *intellective*, and *conditional*. See KNOWLEDGE.

CONDIVI, ASCANIO, in *Biography*, an artiſt whoſe works of painting and ſculpture are now unknown. He is indeed ſaid to have poſſeſſed but an humble ſhare of talent, inſomuch that although he had the good fortune to be the inmate and diſciple of the great Michelangelo Buonaroti for many years, he never attained eminence.

The world however has obligations to Condivi for the life which he wrote of his maſter, in ſomewhat the form of a journal, and which he publiſhed in 1553, ten years prior to the death of Michelangelo. Mr. Mariette, the celebrated connoiſſeur, was decidedly of opinion that the greater part of this narrative was written abſolutely under the immediate inſtigation and guidance of Michelangelo himſelf, and of courſe conſidered it as infinitely more authentic than the florid, but haſty, compoſition of Vaſari. Vaſari had publiſhed a life of the great Florentine artiſt in his firſt edition of 1550. Condivi points out and corrects many of his errors. This Vaſari indignantly reſents in his ſecond edition of 1568; but as Michelangelo was then no longer alive to decide their reſpective claims, the veracity of Condivi ſhould ſuffer no imputation. Vaſari however relates many things which the other omits, dwells more largely upon others, and in his ſecond edition gives us the ſequel of Michelangelo's life, with a long deſcription of his magnificent funeral, &c. it was therefore deſirable to unite theſe and other ſcattered materials into one work: this has lately been done by Mr. Duppa in a handſome quarto volume.

The firſt edition of Condivi is in quarto and become rare. Another edition, with copious notes by Antonfranceſco Gori and Mariette, together with extracts from Vaſari, was publiſhed in Florence, 1746, in folio.

CONDIVICNUM, in *Ancient Geography*, *Nantes*, a town of Gallia Lyonnenſis, according to Ptolemy, and capital of the Namneti, from whom it took its name.

CONDOCHATES, a river of India, on the other ſide of the Ganges, according to Pliny and Arrian, which diſcharged itſelf into the Ganges, about the 26th degree of latitude.

CONDOLENCE, in *Ethics*. See COMMISERATION.

CONDOM, in *Geography*, a town of France, in the department of the Gers, and chief place of a diſtrict, ſituated in a beautiful valley on the river Baiſe, 27 miles N.W. from Auch, and 60 S.E. from Bourdeaux. It has a ſub-prefect and a court of juſtice. The place contains 6917, and the canton 13,232 inhabitants. The territory of the canton includes 247½ kiliometres and 16 communes. The whole diſtrict counts 128 communes and 67,103 inhabitants, upon a territorial extent of 1662½ kiliometres. Its ſoil is in general fertile, except in the ſouthern part, which is an extenſive barren heath; but as there are many marl pits, the waſte land is improved with marl, which renders it tolerably fertile for a term of 20 years, at the end of which the ground is ſuffered to lie waſte again, and another extent of heath is rendered productive upon the ſame plan. Corn, wine, and brandy are the chief articles of trade, moſt of which are ſent to Mont de Marſan and Bourdeaux.

CONDOMOIS, a country of France, before the revolution, of which Condom was the capital.

CONDOMA, in *Zoology*, the name given by Buffon to the ſtriped antelope of Pennant, the antilope ſtrepſiceros of Gmelin's Linnæus, the cervus capenſis, or cape deer, of Collin. Act. Ac. Theod. Palat. 1. 487, the bos ſtrepſiceros of Aldrovand, the ſtrepſiceros of Caius, Geſner, and Jonſton, and the wild goat of Kolben, &c. It has long, compreſſed, wrinkled, tapering, ſharp-pointed ſpiral horns, with a ridge on one ſide which follows the wreaths; the body has a white line along the back, and ſeveral white ſtripes acroſs from that down the ſides towards the belly and thighs. This animal inhabits the country near the Cape of Good Hope. It is near nine feet long from the noſe to the rump, and four feet high at the ſhoulders; the body is long, ſlender, and of a reddiſh-grey colour; the face is brown, having a white line from the corner of each eye, running forwards and uniting above the noſe; the tranſverſe ſtripes above-mentioned are, in general, ſeven in number, four of which point towards the thighs, and three to the belly; it has a ſhort mane on the neck, and long hairs hanging down from the throat to the breaſt; the breaſt and belly are grey; the tail, two feet in length, is brown above, white on the under ſide, and black at the end; the horns are of a duſky colour, and naturally wrinkled, though ſuch as are brought to Europe are highly poliſhed; they are near four feet long, cloſe at the baſes, above two feet and a half diſtant at the points, and have two ſpiral ſcrew-like turns. The female has no horns. It is ſaid to leap with ſurpriſing activity to a great height.

CONDORCET, JEAN ANTOINE, NICHOLAS CARITAT, *Marquis of*, in *Biography*, celebrated as a writer and political character, was deſcended from an ancient family in Picardy in France. He was born in 1743, and was educated at the college of Navarre, where he exhibited an ardent thirſt for phyſical and mathematical purſuits, and acquired the reputation of a hard ſtudent. Condorcet firſt attracted public notice as a mathematician, by his treatiſe "On Integral Calculations," which he wrote when he was only twenty-two years of age, and in which he propoſed to exhibit a general method of determining the finite integral of a given, differential equation, either for differences infinitely ſmall, or finite differences. D'Alembert and Bezout, the commiſſioners of the academy, employed to examine the merits of this performance, declared that the greater part of the methods were of the author's own invention, that the production itſelf indicated a degree of knowledge very ſeldom to be met with at ſo early an age, and that it afforded a preſage of talents worthy of being excited by the approbation of the academy. This was followed by his "Eſſay on Analyſis," and other works, which ſhewed his ſkill in analytical reſearches. In the year 1769, he was admitted member of the Academy of Sciences, the memoirs of which were enriched by various diſquiſitions preſented by him on the moſt abſtruſe ſubjects. During the adminiſtration of Turgot, celebrated no leſs for his integrity, than for his high talents, Condorcet was applied to for aſſiſtance in arranging plans for economical reforms in the ſtate. In 1773 he was appointed ſecretary to the Academy of Sciences, when he compoſed eulogies upon ſeveral deceaſed members who had been neglected by Fontenelle. At this period he was the friend and intimate aſſociate of Voltaire, D'Alembert, and other diſtinguiſhed characters. Like D'Alembert he united in himſelf the reputation of an elegant writer, and of profound ſcience; and in 1782 he was received into the French Academy, on which occaſion he delivered a diſcourſe concerning the influence of philoſophy. In the following year he ſucceeded D'Alembert as ſecretary to that academy, and pronounced an able eulogy to the memory of his deceaſed friend, whoſe literary and ſcientific merits are ſet forth with great ability. The death of Euler afforded Condorcet another opportunity of diſplaying his own talents by appreciating thoſe of the departed mathematician. In his diſcourſe on this occaſion, he exhibited a clear and ſcientific ſtatement of the improvements and inventions introduced into one department of knowledge by the exertions of an individual. The lives of Turgot and Voltaire, and the eulogy pronounced upon the death of the celebrated Franklin, were decided teſtimonies to the abilities of Condorcet as a biographical writer. Turgot had occupied much of his time and attention with moral and political ſciences, and was particularly anxious, for the good of his fellow creatures, that the certainty of which different ſpecies of knowledge are ſuſceptible, might be demonſtrated by the aſſiſtance of calculation, hoping that the human ſpecies would neceſſarily make a progreſs towards happineſs and perfection, in the ſame manner as it had done towards the attainment of truth. To ſecond theſe views of Turgot, Condorcet undertook a work replete with geometrical knowledge. He examined the probability of an aſſembly's rendering a true deciſion, and he explained the limits to which our knowledge of future events, regulated by the laws of nature, conſidered as the moſt certain and uniform, might extend. If we do not poſſeſs a *real*, yet he thought, we have at leaſt a *mean* probability, that the law indicated by events, is the ſame conſtant law, and that it will be perpetually obſerved. He conſidered a forty-five thouſandth part as the value of the riſk, in the caſe when the conſideration of a new law comes in queſtion; and it appears, from his calculation, which we cannot go into, that an aſſembly conſiſting of 61 votes, in which it is required that there ſhould be a plurality of nine, will fulfil this condition, provided there is a probability of each vote being equal to four-fifths, that is, that each member voting ſhall be deceived only once in five times. He applied theſe calculations to the creation of tribunals, to the forms of elections, and to the deciſions of numerous aſſemblies; inconveniences attendant on which were exhibited by him This work furniſhed a grand, and at the ſame time, an agreeable proof of the utility of analyſis in important matters to which it had never before been applied.

Condorcet at this time ſtarted the idea of a dictionary, in which objects are to be diſcovered by their properties, inſtead of being ſearched for by their reſpective names; he alſo intimated a ſcheme for conſtructing tables, by which ten milliards of objects might be claſſed together by means of only ten different modifications. The talents of Condorcet were very various, and he diſtinguiſhed himſelf by many philoſophical and economical diſcuſſions, which it is ſuppoſed, with great juſtice, had a great ſhare in producing the ſubſequent important revolution in France. Without pretending to decide upon the motives of thoſe who were active in achieving the downfal of the French monarchy, we ſhall bring before the reader a brief account of the part which Condorcet took in this buſineſs. Almoſt all his writings tended to pave the way for that moſt important change in government which took place in the year 1789. At this period, and in the following two or three years, he engaged in ſeveral periodical publications, with a view, no doubt, of guiding the public mind. He was a member of the popular clubs at Paris, particularly that of the jacobins, celebrated for democratic violence, where he was a frequent but by no means a powerful ſpeaker. He was choſen a repreſentative for the metropolis, when the conſtituent aſſembly was diſſolved, and joined himſelf to the Briſſotine party which, in point of real talents and integrity, were not inferior to any of the contending factions of the day. But they wanted energy to control the people, and finally fell victims to that revolutionary ſpirit which they had excited. Condorcet at this period was the perſon ſelected from the party to draw up a plan for public inſtruction, which he comprehended in two elaborate and very ſtriking memoirs; the principles laid down were, perhaps, too abſtract for general uſe, and too refined for the preſent ſtate of ſociety. He was the author of a manifeſto addreſſed from the French people to the powers of Europe, on the approach of war; and of a letter to Louis XVI., as preſident of the aſſembly, which was dictated in terms deſtitute of that reſpect and conſideration to which the firſt magiſtrate of a great people has, as ſuch, a juſt claim. Condorcet attempted alſo to juſtify the inſults put upon the ſovereign by the loweſt, the moſt illiterate, and moſt brutal part of a delirious populace. On the trial of the king, his conduct was equivocal and unmanly; he had declared that he ought not to be arraigned, yet he had not courage to defend his opinion or juſtify thoſe ſentiments which he had deliberately formed in the cloſet.

After the death of Louis, Condorcet undertook to frame a new conſtitution, which was approved by the convention, but which did not meet the wiſhes and expectations of the nation. A new party, calling themſelves the MOUNTAIN, were now gaining an aſcendancy in the convention over Briſſot and his friends. At firſt the conteſt was ſevere; the debates, if tumult and diſcord may be ſo denominated, ran high, and the utmoſt acrimony was exerciſed on all ſides. Condorcet always timid, always anxious to avoid danger, retired as much as poſſible from the ſcene. By this act of prudence he at firſt eſcaped the deſtruction which overwhelmed the party; but having written againſt the bloody acts of the mountain, and of the monſter Robeſpierre, a decree was readily obtained againſt him. He was arreſted in July 1793, but contrived to eſcape from the vigilance of the officers under whoſe care he was placed. For nine months he lay concealed in Paris, when dreading the conſequences of a domiciliary viſit, he fled to the houſe of a friend on the plain of Mont-Rouge, who was at the time in Paris. Condorcet was obliged to paſs eight-and-forty hours in the fields, expoſed to all the wretchedneſs of cold, hunger, and the dread of his enemies. On the third day he obtained an interview with his friend; he, however, was too much alive to the ſenſe of danger to admit Condorcet into his habitation, who was again obliged to ſeek the ſafety which unfrequented fields and pathleſs woods could afford. Wearied at length with fatigue, and want of neceſſary ſuſtenance, he went to a public-houſe, and aſked for an omelette, which he devoured with ſo much greedineſs as to induce the ſuſpicion of a municipal officer who was preſent. At this period, ſuſpicion and guilt were divided by very narrow boundaries; the unfortunate man was ſeized and thrown into a dungeon, in order that he might, on the following day, be conducted to the bloody tribunal at Paris. The precaution was, however, unneceſſary. Condorcet was found dead in the morning; and as it was generally underſtood that he was never without a concealed doſe of the moſt active poiſon, to this cauſe his melancholy end was generally aſcribed. Such was the concluding ſcene of the career of a man who had ſuſtained a brilliant part on the ſtage of life. He died March 28, 1794.

His character has been variouſly eſtimated. His manners were mild, and his talents were unqueſtionably of the firſt order. He is ſaid to have been deſtitute of thoſe fine feelings which diſtinguiſh great and generous minds; and it is allowed on all hands that he was a prey to timidity; a paſſion which at length induced him to commit the act of ſuicide. By Madame Rolande, his contemporary and intimate, he was, in his life-time, thus deſcribed: "The genius of Condorcet is equal to the comprehenſion of the greateſt truths; but he has no other characteriſtic beſides fear. It may be ſaid of his underſtanding, combined with his perſon, that it is a fine eſſence abſorbed in cotton. The timidity which forms the baſis of his character, and which he diſplays even in company, on his countenance and in his attitudes, does not reſult from his frame alone, but ſeems to be inherent in his ſoul, and his talents furniſh him with no means of ſubduing it. Thus, after having deduced a principle, or demonſtrated a fact in the aſſembly, he would give a vote decidedly oppoſite, overawed by the thunder of the tribunes, armed with inſults, and laviſh of menaces. The propereſt place for him was the ſecretaryſhip of the academy. Such men ſhould be employed to write, but never permitted to act." Condorcet was married, and lived on the moſt affectionate terms with his wife. He left one daughter, who has, during the preſent ſummer (1807), been married to Arthur O'Connor.

Condorcet was the correſpondent of the great Frederic, and of Catherine, the empreſs of Ruſſia. "Letters to the King of Pruſſia," he publiſhed during his life; and he left behind him, which appeared as a poſthumous work, "A Sketch of a Hiſtorical Draught of the Human Mind." In this work, he conſiders man as he has been, as he is, and as he may be; and he inculcates, with great energy, his favourite idea of the perfectibility of the human ſpecies, and of its advance to actual perfection. He left behind him alſo "A Treatiſe on Calculation," and "An Elementary Treatiſe on Arithmetic." His work on the human mind was written during the months that he ſecreted himſelf from the ſavages who were ſeeking for his blood, with more than inhuman fury; and it is remarkable, and to the credit of the writer, that under ſuch circumſtances, dreading death at every inſtant, he could compoſe ſo able a treatiſe, and feel the conviction of the progreſs of his fellow creatures towards moral improvement. Memoirs of the French Revolution. Rolande's Memoirs.

CONDORE, or Pulo Condore, in *Geography*, an iſland of the Eaſt Indian ocean, about 20 leagues from the coaſt of Cochin-china, taking its name from two Malay words, *Pulo* ſignifying an iſland, and *Condore* a calabaſh, of which it produces great quantities. This iſland is high and mountainous, and ſurrounded by ſeveral ſmaller iſlands, ſome of which are leſs than one, and others two miles diſtant. It is of the form of a creſcent, extending, ſays Capt. King, near 8 miles from the ſouthernmoſt point, in a N.E. direction, and its breadth no where exceeds 2 miles. Sir Geo. Staunton ſays, it is 11 or 12 miles in length, and about 3 in breadth, conſiſting of a ridge of peaked hills. From the weſternmoſt extremity, the land trends to the S.E. for about 4 miles, and oppoſite to this part of the coaſt there is an iſland, called by Monſ. D'Aprés "Little Condore," which runs two miles in the ſame direction. This poſition of the two iſlands forms a ſafe and commodious harbour, the entrance into which is from the north-weſt. The diſtance between the two oppoſite coaſts is ¾ of a mile, excluſive of a border of coral rock, which runs down along each ſide, extending about 100 yards from the ſhore. The anchorage is very good, from 11 to 5 fathoms water, but the bottom is ſo ſoft and clayey, that great difficulty occurs in weighing the anchors. Toward the bottom of the harbour, there is ſhallow water for about half a mile, beyond which the two iſlands approach ſo near each other, as to leave only a paſſage at high water for boats. The moſt convenient place for watering is at a beach on the eaſtern ſide, where is a ſmall ſtream that furniſhes 14 or 15 tons of water a day. Sir George Staunton ſays, that beyond the beach, which ſtretches acroſs two-thirds of the entrance, at the ſouthern extremity of the ſpacious bay on the eaſtern ſide of the iſland, there is a ſafe paſſage to the inner part of the bay, the north of which is ſheltered by a ſmall iſland lying to the eaſtward. The whole of the bay, he ſays, is formed by four ſmall iſlands, which approach ſo nearly to each other as to appear, from ſeveral points, to join. They all ſeem to be the rude fragments of primitive mountains, ſeparated from the great continent in the lapſe of time. This iſland has convenient anchoring-places in either monſoon; and ſir Geo. Staunton ſtopped there, on the 17th of May, in a ſpacious bay on the eaſtern ſide of the iſland. Capt. Gore, on the 20th of January, ſtood for the harbour on the S.W. end of the iſland, which, having its entrance from the N.W. is the beſt ſheltered during the N.E. monſoon.

This iſland, both with reſpect to animal and vegetable productions, is conſiderably improved, ſince the time when Dampier viſited it. Neither that writer, nor the compiler of the Eaſt Indian Directory, mention any other quadrupeds beſides hogs, which are ſaid to be very ſcarce, lizards, and the guanoes; and the latter, on the authority of Monſ. Dedier, a French engineer, who ſurveyed the iſland about the year 1720, ſays, that none of the fruits and eſculent plants, ſo common in the other parts of India, are to be found here, except water-melons, a few potatoes, ſmall gourds, *chibbols* (a ſmall ſpecies of onion), and little black beans. At preſent, beſides the buffaloes, of which there are large herds, it ſupplies remarkably fine fat hogs, of the Chineſe breed. There are alſo ſome of the wild ſort in the woods, which alſo abound with monkies and ſquirrels. One ſpecies of the ſquirrel is of a beautiful ſhining black colour, and another ſpecies is ſtriped brown and white, which is called the flying ſquirrel, from its being provided with a thin membrane, reſembling the wing of a bat, extending on each ſide of the belly, from the neck to the thighs, which, in ſtretching out the legs, ſpreads, and enables it to fly from tree to tree, to a conſiderable diſtance. Lizards are found in great abundance; but Capt. Gore ſays, that none of his company diſcovered the guano, and another animal deſcribed by Dampier as reſembling the guano, only much larger. Among the vegetable improvements of the iſland are fields of rice and tobacco, and groves of cabbage palm-trees, plantains, various kinds of pompions, cocoa-nuts, oranges, ſhaddocks, and pomegranates. Theſe improvements are aſcribed to the French, for the purpoſe of making it a more convenient refreſhing ſtation for any of their ſhips that may be bound for Cambodia, or Cochin-china; and for this purpoſe it is well ſituated. The woods are well ſtocked with feathered game; and particularly with wild hens and cocks, reſembling thoſe of our own country. The land in the neighbourhood of the harbour is a continued high hill, richly adorned with a variety of fine tall trees, from the ſummit to the water's edge; and among others the tea-tree deſcribed by Dampier.

The town in this iſland is ſituated near the ſea ſide, at the bottom of a retired bay, which affords a ſafe road-ſtead during the prevalence of the S.W. monſoon. It conſiſts of between 20 and 30 houſes, built cloſe together; beſides ſix or ſeven others that are ſcattered about the beach. The roof, the two ends, and the ſide fronting the country are neatly conſtructed of reeds; the oppoſite ſide, facing the ſea, is entirely open; but by means of a fold of bamboo ſcreens, they can exclude or let in as much of the ſun and air as they pleaſe. There are other large ſcreens or partitions, for the purpoſe of dividing, as occaſion requires, the ſingle room, of which the houſe properly ſpeaking, conſiſts, into ſeparate apartments. The largeſt houſe of the town, belonging to the chief or captain, had a room at each end, ſeparated by a partition of reeds from the middle ſpace, which was open on both ſides, and provided with partition-ſcreens like the others. It had, beſides, a pent-houſe, projecting four or five feet beyond the roof, and running the whole length on each ſide. At each end of the middle room were hung ſome Chineſe paintings, repreſenting men and women in ludicrous attitudes. In this apartment Capt Gore's companions were civilly deſired to ſeat themſelves on mats, and they were preſented with betel. In one of the apartments, viſited by ſir George Staunton, was an altar decorated with images; and the partitions were hung with figures of monſtrous deities; but the countenances and deportment of the people exhibited no idea of religious awe, nor was any perſon obſerved in the poſture of prayer or adoration. A few ſpears ſtood againſt the wall with their points downwards, together with ſome match-locks, and a ſwivel-gun.

The inhabitants of this iſland, who are fugitives from Cambodia and Cochin-china, are not numerous. They are of a ſhort ſtature, very ſwarthy, and of a feeble, unhealthy aſpect, but ſeemingly of a gentle diſpoſition. The dreſs of theſe people is compoſed chiefly of blue cotton, worn looſely about them; and their flat faces and little eyes indicate a Chineſe origin or relation. Their colloquial language is altogether different from that which is ſpoken in China, but their written characters are all Chineſe.

The Engliſh ſettled in this iſland in 1702, when the factory of Chuſan, on the coaſt of China, was broken up, and brought with them ſome Macaſſar ſoldiers, who were hired to aſſiſt in building a fort; but the preſident not fulfilling his engagement with them, they watched an opportunity, and in one night murdered all the Engliſh in the fort. Thoſe without the fort, hearing a noiſe, took the alarm, and ran to their boats, very narrowly eſcaping with their lives; but not without much fatigue, hunger, and thirſt, to the Johore dominions, where they were treated with great humanity. Some of them afterward went to form a ſettlement at Banjer-Maſſin, in the iſland of Borneo. Since this event, no Europeans have ever reſided in this iſland. The latitude of this iſland, calculated from a meridional obſervation, as ſtated by ſir Geo. Staunton, is 8° 40′ N.; and its longitude, according to a good chronometer, 105° 55′ E. The harbour in which Capt. Gore was ſtationed, is in N. lat. 8° 40′. E. long., deduced from a great number of lunar obſervations, 106° 18′ 46″; dip of the N. pole of the magnetic needle, 2° 1′; variation of the compaſs, 0° 14′ W.; high water at the full and change of the moon, 4^h 16′ apparent time. The water roſe and fell 7 feet 4 inches perpendicular. Voyage to the Pacific Ocean, by captains Cook, Clerke, and Gore, vol. iii. p. 450. &c.

Condore, in *Ornithology*, the *Vultur Gryphus* of Latham, (Ind. Orn.) Klein, Briſſon, Borowſk., the cuntur of Laet and Ray, the conder of Frezier, Condamine, Buffon, and Molina, and the condor of Latham (Syn. and Sup.) is a bird of enormous ſize, having a longitudinal warty excreſcence on the crown of the head, and a naked throat. It inhabits South America; and its ſize is ſo enormous that the wings, when extended, meaſure 9, 12, or even 16 feet from top to tip; the largeſt quill-feathers of the wings ſometimes meaſure $2\frac{1}{2}$ feet in length, and the quill-part $1\frac{1}{2}$ inch in circumference. The body is of a black colour, with a white back; the neck is ſurrounded with a collar of longiſh white feathers; the chin is reddiſh; the head is clothed with brown down or wool; the eyes are black, with cheſnut or light reddiſh irides; the bill is black, with a whitiſh point; the legs and feet are black, and the claws are ſtraightiſh; the tail is ſmall. The female is conſiderably larger than the male, which it reſembles, except in having a crown creſt or tuft on the ſcrag, or hinder part of the neck. The condore builds its neſt on the higheſt mountains, under the ſhelter of ſome projecting ſhelf of a rock, in which the female lays two white eggs. It preys on calves, ſheep, goats, and ſuch animals, and when very much preſſed by hunger, it has been known to carry off children of ten years of age; and two of them are ſaid to be able to devour the carcaſe of a cow at one meal. When it alights upon the ground, or riſes from it, the noiſe it makes with its wings is ſuch as to terrify, and almoſt to deafen, any one who happens to be near the place. Don Ulloa informs us, that he actually ſaw one of them riſing with a lamb in its talons. The Indians have various ways of catching them: beſides traps and ſnares laid for them near any carrion, they kill a cow or other animal, and moiſten its fleſh with the juice of ſome ſtrong intoxicating herbs, and then bury the body till it putrefies. In this ſtate they take it up and lay it on the ground; and when the condores come near to devour it, they are intoxicated and rendered motionleſs, when the Indians fall upon and kill them.

CONDORMIENTES, religious ſectaries, whereof there have been two kinds. The firſt aroſe in Germany, in the thirteenth century; their leader was a native of Toledo. They held their meetings near Cologne; where they are ſaid to have worſhipped an image of Lucifer, and to have received anſwers and oracles from him: the legend adds, that an eccleſiaſtic having brought the euchariſt to it, the idol broke into a thouſand pieces; which put an end to the worſhip. They had their name from their *lying all together*, men and women, young and old.

The other ſpecies of Condormientes were a branch of Anabaptiſts in the ſixteenth century; ſo called, becauſe they lay, ſeveral of both ſexes, in the ſame chamber; on pretence of evangelical charity.

CONDOTTIERI, in the Italian *Policy*, denoted leaders of bands, who, in the 15th and 16th centuries, made a trade of war, and raiſed ſoldiers in order to hire them out to different ſtates.

CONDREN, Charles de, in *Biography*, ſuperior general of the fathers of the oratory, was born near Soiſſons in the year 1588. By his father, who was in high eſtimation in the court of Henry IV., he was deſigned either for a poſt about the king, or for the military profeſſion. His own inclinations, however, led him to think of the church, as moſt ſuited to his talents, to which, after ſome heſitation, his father gave an aſſent. He accordingly proſecuted his ſtudies in the college of the Sorbonne at Paris, was ordained prieſt, and admitted a doctor of that ſociety in the year 1614. In the following year he became a member of the congregation of the oratory, and founded ſome houſes belonging to that order. He was not long in obtaining a diſtinguiſhed reputation for integrity and prudence as a man, and for piety and benevolence as a prieſt. On account of theſe traits in his character he was fixed upon as the moſt proper perſon to be confeſſor to the duke of Orleans, only brother to Louis XIII. In this ſituation he was ſucceſsfully employed in confidential buſineſs between the duke and the king, and was the happy means of reſtoring theſe princes to a mutual good underſtanding with one another, after long and violent diſagreements. For theſe ſervices he was offered the archbiſhopric of Lyons, and a cardinal's hat; but he declined accepting offices of honour and emolument for having performed thoſe acts, which, his religion taught him, were binding upon every Chriſtian. He died in the year 1641, leaving behind him many pieces which evidenced ſuperior talents, and a ſincere piety. His principal works are, "Diſcourſes and Letters," 2 vols. 12mo. 1648; and "An Explanation of the Prieſthood of Jeſus Chriſt," publiſhed in 1677. Father Amelotte drew up an account of his life, in which there is a collection of his letters and maxims with an expoſition of his opinions. Nouv. Dict. Hiſt.

CONDRIEUX, in *Geography*, a ſmall town of France, in the department of the Rhône, at the foot of a hill on the river Rhône, 21 miles ſouth from Lyons. This place is celebrated for its excellent ſweet wine.

CONDROS, CONDROTZ, in *Geography*, is a tract of land in the circle of Weſtphalia, ſituated in the biſhopric of Liege, which formed part of the German empire, and is now incorporated with France. Condruſi, in ancient geography, was reckoned part of Belgica. Huy, which was conſidered as the principal town of Condros, is, at preſent, the chief place of the diſtrict of the ſame name in the department de l'Ourthe. See HUY.

CONDUCT, *ſafe*. See SAFE-*conduct*.

CONDUCTOR (from *conduct*, and *to conduct* from the French *conduire*) *prime*, in *Electricity*, is a body of a conducting ſubſtance, (*viz.* ſuch as will tranſmit the electric power or fluid) placed immediately before the glaſs cylinder, or globe, or plate, or other excitable body, of an electrical machine. Its office is to collect the electricity, and to convey it either in the form of ſparks, or ſilently, to other bodies that may be preſented to it in the courſe of experiments. Without this prime conductor no large ſparks could be drawn immediately from the excited electric, becauſe the electric body, being in its nature incapable of conveying the electric fluid through its ſubſtance, diſcharges, on a body which is preſented to it, that quantity of electricity only which is accumulated upon a ſmall part of its ſurface. But when the prime conductor is placed before the excited electric, the former ſucceſſively collects all the electricity from the ſurface of the latter, whilſt revolving; and if a proper body be brought near its ſurface, the electricity which has been accumulated, will ruſh from every part of the ſurface of the prime conductor in a copious ſtream, or in a full ſpark, to that body.

The forms of prime conductors have been continually varied from the very firſt invention of electrical machines, according as new diſcoveries, or the progreſs of experience, have either detected former defects, or ſuggeſted more advantageous forms. A gun-barrel, or a metallic chain, ſupported by ſilk ſtrings, formed the prime conductor of the earlieſt electrical machines, *viz.* ſuch as were uſed towards the beginning of the laſt, or eighteenth century. And in conſequence of this uſage ſome diſtinguiſhed late writers on the continent, have retained the name of *chain* for the prime conductor, long after the ſhape of that inſtrument had undergone a total alteration. See "l'Elettriciſmo artificiale del P' Beccaria."

Though the gun-barrel or the chain would be highly improper for the modern electrical machines, either of them was quite ſufficient for thoſe of the old conſtruction, in which the excitation was very ſlight and difficultly obtained. But when the glaſs globes or cylinders began to be made much larger, when a better method of excitation was diſcovered, and eſpecially when Mr. Canton's amalgam was introduced, to which the great power of the modern electrical machines is principally owing; then the chain or the gun-barrel was found incapable of retaining the electric power, ſo that every narrow edge, or point, or curvature of the ſame, was found to diſſipate the electricity into the ſurrounding air, as could be eaſily perceived in a darkened room. This ſuggeſted the idea of enlarging the ſize, and ſmoothing the irregularities of the prime conductor, in conſequence of which ſome prime conductors were made of braſs, others of tin, or even of gilt paper; and their ſhape became much more regular and compact. A cylinder with ſpherical terminations has been the moſt uſual form of prime conductors. A few were made ſpherical; Dr. Prieſtley uſed one of a pear-like figure, and ſome have alſo been made of other fanciful ſhapes. But amongſt all thoſe forms, that which the practice of the beſt electricians has found to be, upon the whole, the moſt eligible, is the abovementioned one of a cylinder with hemiſpherical terminations. Thoſe terminations, in ſmall prime conductors, ſometimes are made a little larger in diameter than the cylinder; but in the prime conductors of the larger kind, they do not project beyond the ſurface of the cylindrical part. As the conducting nature of their ſubſtance muſt be of the beſt kind, the prime conductors are made of metal, at leaſt on their ſurface. The ſmall ones are made of hollow braſs, or tin plates, or of wood covered with tin-foil. But the large ones are almoſt always made of wood, or paſte-board covered with tin-foil. The prime conductors of tin are frequently covered with a black varniſh, which is preſerved cleaner than the ſurface of the tin, and may perhaps in ſome meaſure prevent the diſſipation of electricity from their ſurface. In any conſtruction, care muſt be had, that the ſurface of the prime conductors be quite free from points, and ſharp edges; and if holes are to be made in them, which indeed are neceſſary for the performance of various experiments; theſe ſhould be well rounded off and their edges burniſhed. The prime conductor is generally ſupported in an horizontal poſition, by one or two glaſs ſticks, which proceed from the bottom board of the electrical machine, or from ſeparate wooden ſtands; the extremities of thoſe glaſs ſticks entering a little way within the ſurface of the conductor. The direction of the prime conductor is moſtly perpendicular to the axis of the glaſs cylinder of the machine; but in ſome electrical machines, the conductor, or two conductors, are ſituated parallel to the abovementioned axis. When two conductors are affixed to the machine, one of them, which collects the electric fluid from the excited glaſs, is called the *poſitive conductor*, and the other, which is connected with the rubber, is called the *negative conductor*. At that extremity of the prime conductor, which ſtands neareſt to the glaſs globe or cylinder, when the former is perpendicular to the axis of the latter, or on the ſide when it ſtands parallel, the collector is affixed. See COLLECTOR.

To the oppoſite extremity of the prime conductor which ſtands fartheſt from the glaſs cylinder or globe, a thick braſs wire, with a pretty large and ſmooth braſs ball, is uſually affixed, and from this ball the longeſt and denſeſt ſpark can be drawn; the greateſt endeavour of the electric fluid to eſcape from the prime conductor being made at that extremity. In plate machines, *viz.* where glaſs plates are uſed inſtead of a globe or cylinder, the extremity of the prime conductor is furniſhed with two ſemicircular projections, which carry the collecting points at their extremities. The ſize of the prime conductor muſt be proportionate to the ſize of the machine; for if the prime conductor be too ſmall, the ſparks that are drawn from it will not be of the largeſt ſize poſſible to be obtained with that machine; and, on the other hand, if the prime conductor be too large, the diſſipation of electricity from its ſurface will be very conſiderable. It is difficult to determine the exact ſize which might be the moſt advantageous for a given machine; for even with cylinders of the ſame ſize, different prime conductors might be uſed, according as the glaſs cylinders are more or leſs capable of a vigorous excitation. With one of the largeſt glaſs cylinders ever made in this country, which meaſured two feet in diameter, a prime conductor of wood covered with tin-foil was uſed, which meaſured ſix feet in length and 18 inches in diameter. With a ſmall machine, the cylinder of which was ſeven inches in diameter, a prime conductor of two feet by three inches and a half was found the moſt advantageous. When the electrical machine is to be uſed only for charging a battery, then it will be better to uſe a very ſmall prime conductor.

The forms of the above-mentioned prime conductors are repreſented in the various plates relating to electricity that are contained in this work.

CONDUCTOR *of Lightning.* See CONDUCTORS.

CONDUCTOR, in *Surgery*, is an inſtrument which ſerves as a guide for a ſcalpel, in ſeveral operations which do not allow the ſurgeon's diſcerning the exact courſe or extent of a wound. For inſtance, in opening a fiſtulous orifice, or dilating the abdominal ring in a ſtrangulated hernia.

Conductors are either made of ſteel or of ſilver; and always have a groove on one ſide, to direct the cutting inſtrument. That which ſurgeons employ in cutting for the ſtone is named a GORGET. This is an inſtrument generally made of ſteel, and introduced, in the operation of Lithotomy, through the artificial orifice, into the bladder, in order to widen the neck of the bladder, and facilitate the introduction of the forceps, with which the ſtone is to be extracted. There are two ſpecies of this inſtrument; the one, which is provided with a knob at the top, is termed the *male* gorget; and the other with an excavation, the *female* gorget. See LITHOTOMY.

There is alſo a machine invented by Mr. Walker, by means of which, a patient labouring under a ſimple or compound fracture of the leg, may be conducted with ſafety and convenience from one place to the other, and the extremities of the bones kept in their proper ſituation during the progreſs of the cure.

To this head belong the conducting apparatus invented for the ſame purpoſe by Mr. Theden of Pruſſia, which are uſed in fractures of the ſuperior and inferior extremities. Machines adapted for fractures of the femur have been deſcribed by Mr. Schmucker, and thoſe for other parts by Mr. Theden himſelf. Mr. Richter conceives that theſe machines may be rendered more ſerviceable, by conſtructing them of tinned iron, inſtead of wallnut-tree wood.

CONDUCTORS. In two important branches of natural philoſophy, a marked diſtinction has been obſerved between the various known bodies of the earth; and upon the peculiar properties of the two different claſſes of bodies, which are diſcriminated from each other by the above-mentioned diſtinction, numerous phenomena, of conſequence to the human ſpecies, are abſolutely depending. The two branches, of natural philoſophy, above alluded to, are the ſcience of electricity and the ſubject of heat. In electricity, if an excited piece of glaſs, or an electrified conductor, be touched with the extremity of a ſtick of ſealing-wax, which a man holds by its other extremity; or if it be touched with the extremity of a ſilk ſtring, the electric power will not be diſſipated; but if the electrified body be touched with the extremity of a rod of iron or braſs, held in a manner ſimilar to the ſtick of ſealing-wax, the electric power will be inſtantly diſſipated; *viz.* it will paſs through the metallic rod, and through the perſon that holds it, &c. Hence it evidently appears, that iron or braſs will permit the tranſition of the electric power through its ſubſtance; whereas ſealing-wax or ſilk will not permit it. Therefore, iron, braſs, and all thoſe ſubſtances through which the electric power can be tranſmitted, are called *conductors of electricity;* and all thoſe ſubſtances, which, like the ſealing-wax or the ſilk, will not permit the paſſage of the electric power, are called *non-conductors of electricity*.

A ſimilar diſtinction has been remarked in the ſubject of heat and cold. Take a ſmall piece of charcoal, make it red hot at one end, and in that ſtate it will be found that a perſon may hold it with his fingers within about a quarter of an inch of the red-hot extremity, without feeling any unpleaſant degree of heat; but if an iron rod as thick as the charcoal be rendered red hot at one end, a perſon will not be able to hold it within leſs than four or five inches, at leaſt, of that end; and ſuch is the caſe with all metallic bodies, as well as with ſome other ſubſtances; which ſhews that heat will paſs through certain bodies much more eaſily than through others. Hence thoſe bodies which, like the iron rod, will eaſily tranſmit the heat through their ſubſtance, are called *conductors of heat;* and thoſe which will convey it with great difficulty, are called *non-conductors of heat.* It muſt be obſerved, however, that though heat will paſs incomparably more eaſily through certain bodies than through others; yet there are no bodies that are known to be either perfect conductors or perfect non-conductors of heat. And indeed, the like obſervation, though in a much more limited manner, may be made with reſpect to the conductors of electricity.

In magnetiſm alſo, the name of *conductor of that power* has been given to a ſingle ſubſtance, namely, to ſoft iron; but the peculiar nature of iron in that reſpect, or rather the paſſage of the magnetic power, will be explained under the article MAGNETISM. We ſhall now in an orderly manner ſtate the various particulars which have been aſcertained with reſpect to the above-mentioned two claſſes of bodies; *viz.* firſt with reſpect to electricity, and then with reſpect to heat.

CONDUCTORS *of Electricity.* In endeavouring to point out the true nature of electrical conductors, it becomes neceſſary to give a liſt likewiſe of the non-conductors of that power, ſince theſe two claſſes of bodies gradually approach each other, in proportion as they are leſs perfect of their kind, as far as certain ſubſtances, which ſeem to ſtand in an intermediate ſtate between conductors and non-conductors, ſo as to participate of both. Glaſs, ſealing-wax, amber, ſilk, and ſeveral other bodies, which, by means of friction with a dry and clean hand, are capable of being excited, ſo as to exhibit electrical phenomena, are called *electrics;* and theſe identical bodies have been found to be non-conductors of electricity; hence *electrics* and *non-conductors* mean the very ſame claſs of bodies. In the ſame manner it has been found, that thoſe bodies, which will eaſily tranſmit the electric fluid through their ſubſtance, cannot be excited in the above-mentioned manner; hence *conductors* and *non-electrics* do alſo denote the ſame bodies.

Strictly ſpeaking, as we have already hinted above, there is no ſubſtance which may be called a perfect conductor or a perfect non-conductor of electricity; the electric power finding ſome reſiſtance in its paſſage through the beſt conductors, and being in ſome degree capable of paſſing through the beſt electrics, at leaſt under certain circumſtances. The following liſts contain the conductors and the electrics, or, which is the ſame thing, the non-electrics and the non-conductors. They are diſpoſed in the order of their perfection; that is, the beſt conductors and the beſt electrics are placed at the heads of their reſpective liſts; and thoſe which participate of both, meaning thoſe which are partly electrics and partly conductors, will be found towards the end of each liſt. In this, however, no great accuracy muſt be expected; firſt, becauſe a very accurate diſcrimination is impracticable when ſubſtances are expreſſed under general denominations; and, ſecondly, becauſe the preciſe degree of conducting or non-conducting power in moſt ſubſtances cannot be determined on account of their fluctuating nature.

Conductors.

Gold.
Silver.
Copper.
Platina.
Braſs.
Iron.
Tin.
Mercury.
Lead.
Semi-metals.
Metallic ores; of which the beſt are thoſe which contain a greater proportion of metallic parts, and neareſt to a reguline ſtate.
Charcoal, either of animal or vegetable ſubſtances. The conducting power of charcoal is very equivocal; for ſome pieces of it will hardly conduct at all, and others will ſuffer the paſſage of the electric fluid over their ſurface only, and not through their ſubſtance. The reaſon of this difference is not quite underſtood; but it ſeems owing to the degree of heat that is applied in the proceſs of making them. See Prieſtley's ſecond volume of Obſervations on different Kinds of Air, ſect. xiv.
Animal fluids.
Acids.
Saline ſubſtances.
Hot water.
Cold water.
Salt water.
All other liquids excepting oils.
Red-hot glaſs.
Melted reſin.
Flame, or the effluvia of flaming bodies.
Ice and ſnow; but not below a certain temperature; for Mr. Achard, at Berlin, in January 1776, obſerved that frozen water, or ice, at the temperature of 28° below 0° of Reaumur's ſcale (equal to —13 of Fahrenheit's) was become an electric. He tried his experiments in the open air, where he found that a rod of ice two feet in length, and two inches thick, was a very imperfect conductor at the temperature of 6° below 0° of Reaumur's thermometer, and that it would not conduct in the leaſt at 20° below 0°. By whirling a ſpheroid of ice in a proper machine, he even electrified the prime conductor, ſo as to attract, repel, give ſparks, &c., like any other electric.
Moſt ſaline ſubſtances, of which the metallic ſalts are the beſt.
Earthy and ſtony ſubſtances, of which the hardeſt are the worſt.
Glaſs filled with boiling water, as mentioned by Kinnerſley.
Smoke.
Vapour or ſteam of boiling water.
All compounds, in which different proportions of the above-mentioned ſubſtances enter, are conductors in different degrees.
An imperfect vacuum, or the abſence of air produced by the action of an air-pump. But a perfect Torricellian vacuum is not a conductor of electricity. Mr. Walſh, aſſiſted by Mr. De Luc, having made a double barometer, in which the mercury had been accurately boiled, ſo as to expel all the air from the tube, found that the vacuum in the arched part of this double barometer was not a conductor of electricity, nor any electric light could be ſeen in it. (Prieſtley's Experiments and Obſervations on Elaſtic Fluids, vol. i.) This remarkable diſcovery was afterwards confirmed by the experiments of Mr. Morgan. (Phil. Tranſ. vol. lxxv.)

Electrics.

Glaſs, and all vitrifications, even thoſe of metals.
All gems, of which the moſt tranſparent are generally the beſt.
All reſins and reſinous compounds.
Amber.
Sulphur.
Baked wood, if not ſuffered to imbibe moiſture.
All bituminous ſubſtances.
Wax.
Silk.
Cotton.
All dry and external animal ſubſtances, as feathers, wool, hair, &c.
Paper.
White ſugar and ſugar-candy.
Air, and other gaſes.
Oils.
Dry and complete metallic oxides.
The aſhes of animal and vegetable ſubſtances.
All dry vegetable ſubſtances.
All hard ſtones, of which the hardeſt are the beſt.
Soft ſtones when heated, according to Delaval.
Powders not metallic, according to Delaval.
Ice, at the temperature of —13° of Fahrenheit's thermometer, according to Achard.

According to Mr. Walſh's, and Mr. Morgan's experiments, the Torricellian vacuum ought to be placed at the head of the liſt; but the ſingular nature of a vacuum, though a non-conductor, will hardly entitle it to the name of an electric. We muſt, however, refer all farther obſervations, reſpecting *electrics,* to the article of that denomination;
the

the above liſt having been inſerted in this place merely to elucidate the nature of conductors.

Thus far we have ſtated the number of conductors, and their gradation, with reſpect to common electricity; but that lately diſcovered branch of this ſcience, which is at preſent aſſiduouſly cultivated under the title of Galvaniſm, has pointed out a peculiar arrangement of conductors with reſpect to the order of their capability of conducting that power which affect the limbs of a prepared animal, and of conveying the power of a galvanic, or rather a Voltaic, battery. See the article GALVANISM. Concerning the former of theſe powers, we tranſcribe a liſt, followed by a few remarks, from Cavallo's Treatiſe on Electricity, 4th ed. vol. iii. p. 20; and with reſpect to the latter, we ſubjoin an abridged extract from a paper of Erman, in the Annales de Chimié, Feb. 1807.

Conductors of Animal Electricity, according to Dr. Lind's and Mr. Cavallo's experiments, which however are arranged with diffidence by the latter, conſidering the difficulty of making the arrangement, and that, in this branch of electricity, the metals do not ſeem to act merely as conductors—The liſt begins with the beſt.

" Malleable platina.
Silver.
Gold.
Quickſilver.
Copper.
Braſs.
Tin.
Lead.
Iron.
The human body.
Salt water.
Freſh water."

" The metallic ores are not ſo good conductors as the purified metals themſelves, and their conducting power is various according to the nature of the ores, but even the metallic ſalts are tolerably good conductors.

" It is very remarkable, that the flame of tallow candle, which is a good conductor of common electricity, will not conduct the animal electricity, when placed in a ſhort interruption made in the circuit of communication. Charcoal, placed in the ſame ſituation as the flame of the candle, was alſo found to be a non-conductor, except when it was actually burning, in which ſtate it conducted tolerably well; but Mr. Volta ſays that he has found ſome pieces of charcoal that acted as well as the metals. Dr. Valli obſerved, that human bodies are not all equally good conductors. Out of four perſons in a company, he found that when two of them formed the circuit of communication between the nerve and the muſcles of a frog, the motions took place very readily. When a third perſon formed the circuit, the motions were very weak; but that when the fourth perſon formed the communication no motion took place. This experiment, he adds, was often repeated with the ſame ſucceſs. The effect, however, may be owing to the different dryneſs of the ſkin. Vitriolic acid, and what is very remarkable, alcohol, appear to conduct this property rather better than water.

" The arteries and the veins are not ſo good conductors as the nerves; for when a blood-veſſel forms part of the circuit of communication, the contractions will take place only when nervous ramifications are adhering to it, and if theſe be carefully ſeparated, the motion will not take place. The ſame thing may be ſaid of the tendons, the bones, and the membranes; for when either of thoſe parts is ſeparated from the body, and is introduced in the circle of communication between the muſcles and nerves of a prepared frog, no motion will enſue, excepting, indeed, when thoſe parts are full of moiſture, and are in immediate contact with the nerve of a prepared frog. Dry nerves are not conductors of animal electricity. Dr. Valli found that the internal ſubſtance of a nerve conducts much better than its external, or coat."

Silver and zinc, profeſſor Aldini ſays, will produce contractions in the muſcles of a frog, many hours after it has become inſenſible to the action of either of them, ſeparately uſed.

Mr. Erman, in his paper on two new claſſes of galvanic conductors, ſays that the bodies which may be applied to the poles of a galvanic pile are, I. *Non-conductors.* II. *Conductors.* The conductors are either *perfect* or *imperfect*; and the imperfect conductors are ſo, either with reſpect to *both poles*, or with reſpect to *one of the poles* of a galvanic battery.

I. The *perfect non-conductors* prevent the communication of the power of both poles effectually; and ſuch are glaſs, reſins, ice, and the vapour of water, ſulphur and its flame, amber, but not its flame.

II. The *perfect conductors*, which diſcharge both poles completely, are the metals, and all in the ſame degree.

The *imperfect conductors of both poles.* Theſe, though capable of forming the galvanic circuit, exhibit in their extent effects of two different kinds. Fluid water and bodies impregnated with water are of this nature.

The *imperfect conductors of the poſitive pole only.* Theſe are incapable of forming the galvanic circuit; for when interpoſed between the two poles of the pile, they inſulate the negative power and conduct the poſitive; whence it follows, that the negative becomes charged, whereas the poſitive is conducted. The flame of hydrogen gas, and the flame of the hydrocarbonated bodies, have this property.

Laſtly, *the imperfect conductors of the negative pole only* inſulate the power of the poſitive, and conduct the power of the negative pole. Of this ſort are the flame of phoſphorus and of alkaline ſoaps.

There now remain two other particulars, which demand our examination with reſpect to the conductors of electricity. Theſe are the method of aſcertaining their peculiar degrees of conducting power, and their uſes. The ſimpleſt method of determining whether any given body be a conductor or not, is to affix an electrometer to the prime conductor of an electrical machine, and when the machine is in action, and of courſe the electrometer is diverging, to touch the prime conductor with one extremity of the given body, which the operator holds in his hand by the other extremity; for if, in ſo doing, the electrometer collapſes, the body in queſtion is a conductor; but if the electrometer continues to diverge, that body is a non-conductor. Its degree of conducting power may alſo be, in great meaſure, eſtimated from the quickneſs with which the electrometer loſes its divergency. In the performance of this experiment, the operator ſhould take care that the electric fluid does not run over the ſurface of the body under trial to the hand that holds it, which generally takes place when the machine acts powerfully, and the body in queſtion is not much extended. In this caſe, it becomes proper to ſtop the revolution of the glaſs globe or cylinder, when the body is to be put in contact with the prime conductor. But if the body be very ſmall, it will be ſufficient to uſe a ſimple electrometer only, which may be eaſily cauſed to diverge by means of an excited ſtick of ſealing-wax, and may then be touched with the body in queſtion. Yet all this is not ſufficient to diſcriminate the peculiar powers of ſubſtances that are of the ſame claſs, ſuch as the various metallic ſubſtances, the different ſtones, &c. And for this purpoſe various other means may be adopted, according to the nature of the bodies under examination. The beſt way of determining the peculiar conducting powers of metallic ſubſtances, is to have wires of the different metals drawn through the ſame hole, ſo as to be preciſely of the ſame diameter, and then melt them by the diſcharge of a battery; *viz.* take a wire, of about one-fiftieth of an inch in diameter, and connect it with the outſide of a battery, containing at leaſt thirty ſquare feet of coated ſurface, and connect the other extremity of the wire with one branch of the diſcharging rod. Then, when the battery is charged, touch the wires which proceed from the inſide of it with the other branch of the diſcharging rod, which will force the exploſion to paſs through the wire that has been interpoſed between the battery and the diſcharging rod, generally melting a greater or a ſmaller part of it, according to the nature of the metal. Thus by repeating the experiment ſucceſſively with wires of the ſame length and diameter, but of different metallic ſubſtances; charging the battery conſtantly to the ſame height, which may be eaſily accompliſhed by means of a quadrant electrometer; and meaſuring the length of each wire that has been melted by the exploſion; their various conducting powers may be aſcertained; obſerving that the worſt conductors are more eaſily melted, and *vice verſâ.* Mr. Henley found that the ſame charge melted 4 inches of gold wire, 6 of braſs, 8 of ſilvered copper, 10 of ſilver, and rather more than 10 of iron. In melting wires of a conſiderable length, as for inſtance two or three feet, it often happens that the force of the exploſion barely renders it red hot, without actually melting it. In this caſe, it is curious to obſerve that the redneſs appears firſt on that extremity of the wire which communicates with the poſitive ſide of the battery, and thence proceeds towards the other end of the wire, which ſhews an ocular proof of the theory of a ſingle electric fluid; the wire, however, is not rendered red hot at one extremity before the other, in conſequence of the progreſſive motion of the electric fluid through it, but becauſe that fluid loſes ſome of its impetus in going through the wire, ſo that the wire ſuffers the greateſt effect of the ſhock on that end which the electric fluid enters; in conſequence of which, that ſame end will be rendered red hot much ſooner, and in a greater degree, than thoſe parts which are more remote from it.

When the conducting powers of different fluids are to be aſcertained, the beſt method of performing the experiment is to fill very narrow glaſs tubes, ſuch as are uſed for ſpirit thermometers, with the fluids in queſtion, introducing a pin at each end of the tubes; and to preſent them ſucceſſively to the prime conductor, after the manner already deſcribed. For other kinds of bodies other methods may be adopted for aſcertaining their conducting powers. Theſe, however, need not be particularly deſcribed; firſt, becauſe they may be eaſily derived from thoſe that have been deſcribed above; and, ſecondly, becauſe they muſt be varied according to the nature of the bodies in queſtion. After all, it muſt be acknowledged, that the metals excepted, no very great degree of accuracy can be expected with other ſubſtances; ſince the fluctuation of their conducting powers ariſes from a variety of ſlight, and almoſt imperceptible differences, ſuch as the difference of temperature, of moiſture, of admixture with other ſubſtances, &c. Thus, glaſs itſelf becomes a conductor, when heated to a certain degree; and the very ſame body will conduct more or leſs readily, even by being placed nearer to or farther from certain other bodies.

In conſidering the conducting power of natural bodies, one may naturally aſk, whence does that property ariſe; or how is it, that certain bodies will, whilſt others will not, conduct the electric power? The preſent ſtate of knowledge, however, does not afford a ſatisfactory anſwer to this queſtion. Various ſuppoſitions have been offered by the late Dr. Prieſtley and others; but as they are inſufficient for the explanation of the phenomena, we ſhall not attempt to ſtate them in this place.

The uſes of conductors are remarkable and extenſive, though they are not yet fully aſcertained to the entire ſatisfaction of the ſpeculative philoſopher. In the firſt place, the ſcience of electricity, or the exiſtence of the electric power, would be abſolutely unknown, were it not for the difference of conducting and non-conducting bodies; for otherwiſe the electric fluid which is manifeſted to us, and operates merely by its paſſage from one body to another, could neither be confined nor accumulated in any place; in conſequence of which, its uniform diſperſion throughout the univerſe would remain inactive and unperceived. But the movements of conducting and non-conducting bodies in the world, their contact, or even their approach without any actual contact, condenſes the electric fluid in one place, and rarefies it in another; and this takes place between the clouds and the earth, &c. By the change of their ſtates of exiſtence, ſome bodies abſorb from other bodies; and others depoſit upon other bodies conſiderable quantities of electric fluid. Thus, a perpetual and ample circulation of that fluid is continually kept up amongſt all the ſubſtances of the terraqueous globe, whence thunder and lightning, vaporization, and probably ſeveral other important operations of nature, are derived. In order to underſtand the action of conductors when oppoſed to each other, ſee the nature of electric atmoſpheres under the article ELECTRICITY.

The greateſt advantage which mankind have derived from the knowledge of the preſent ſubject, is the adoption of a conductor for the preſervation of buildings and veſſels againſt the dire effects of lightning. The identity of electricity and lightning proved by Dr. Franklin, and his ſubſequent introduction of conductors for preſerving buildings, form two of the grandeſt diſcoveries of the laſt century. It was propoſed by the above-mentioned philoſopher to raiſe a metallic conductor ſome feet above the higheſt part of the building, to continue the ſame down along the outſide of the wall, and below it, deep into the earth, or, which is preferable, to connect it with ſome well or drain. By theſe means the houſe would have little to apprehend from a ſtroke of lightning; for, ſince an electrified body is well known to ſtrike the neareſt and beſt conductors that may happen to be in its way, it is evident that the conductor ſituated in the abovementioned manner, being of metal, and higher than any part of the building, would naturally be ſtruck by the lightning in preference to any other part, and would conduct it to the ground, without any damage to the building.

This reaſonable propoſal was no ſooner offered by the ſagacious Franklin, than it was adopted in America, in Europe, and elſewhere. Numerous facts ſoon proved the uſefulneſs of ſuch conductors, and extended its adoption; by ſhewing that ſeveral houſes, which before had been repeatedly ſtruck by the lightning, eſcaped unhurt after the application of the conductor; that, in many places, the conductors of houſes were actually ſtruck by the lightning, which melted them about their extremities, yet the houſes themſelves received no injury; and ſo forth.

Though the conductors were inſtantly adopted, yet their moſt uſeful form, eſpecially with reſpect to their upper termination, has been much controverted; and it is but lately that the true ſtate of the queſtion has been elucidated. The queſtion was, whether the conductors ſhould terminate in a point, according to Dr. Franklin's original propoſal, or in a ball. Mr. B. Wilſon exhibited ſome experiments, in which a point was ſtruck at a greater diſtance than a ball; whence he concluded, that as the point would attract the lightning from a greater diſtance, a blunt termination ought to be preferred, ſince, in certain caſes, it would avoid a ſtroke of lightning, which the pointed termination would not. (Phil. Tranſ. for 1778). Mr. Nairne, on the other hand, ſhewed ſome experiments, in which a ball was ſtruck in preference to a point. And this indeed is confirmed by a great variety of other experiments. In ſhort, a pointed conductor will draw the electric fluid from an incomparably greater diſtance than a blunt one; but it will draw that fluid gradually, in a ſtream, or ſilent manner; whereas the blunt termination will receive it in a full ſpark, or at once; hence a pointed conductor will tend to diminiſh the quantity of electricity in a cloud, previous to its coming too near, and thus it may protect a greater extent of building than a conductor with a blunt termination, ſince the object of fixing a conductor to a houſe is to protect the houſe from the effects of lightning, and not the conductor from tranſmitting the matter of the lightning.

Upon the whole, conſidering the immenſe quantity of electricity in a thunder cloud, and the little difference between the action of a blunt or a ſharp conductor with reſpect to that quantity, the difference of thoſe terminations ſeems to be of leſs conſequence than it was apprehended in the fervour of the diſpute. After all the experiments and the diſcuſſions made for the purpoſe, "A conductor," Mr. Cavallo obſerves, "to guard a building, as it is now commonly uſed in conſequence of ſeveral conſiderations and experiments, ſhould conſiſt of one iron rod, (copper would do much better, it being a more perfect conductor of electricity, and at the ſame time not being ſubject to contract ruſt ſo ſoon as iron), about three quarters of an inch thick, faſtened to the wall of the building, not by iron cramps, but by wooden ones. If the conductor were quite detached from the building, and ſupported by wooden poſts at the diſtance of one or two feet from the wall, it would be much better for common edifices; but it is more particularly adviſable for powder-magazines, powder-mills, and all ſuch buildings as contain combuſtibles ready to take fire. The upper end of the conductor ſhould be terminated in a pyramidal form, with the edges, as well as the point very ſharp; and if the conductor be of iron, it ſhould be gilt or painted for the length of one or two feet. This ſharp end ſhould be elevated above the higheſt part of the building, (as above a ſtack of chimnies, to which it may be faſtened), at leaſt five or ſix feet. The lower end of the conductor ſhould be driven five or ſix feet into the ground, and in a direction leading from the foundations; or it would be better to connect it with the neareſt piece of water, if any be at hand. If this conductor, on account of the difficulty of adapting it to the form of the building, cannot conveniently be made of one rod, then care ſhould be taken, that where the pieces meet they be made to come in as perfect a contact with one another as poſſible; for the electricity finds conſiderable obſtruction where the conductor is interrupted. For an edifice of a moderate ſize, one conductor, in the manner already deſcribed, is perhaps ſufficient; but, in order to ſecure a large building from ſuſtaining any damage by lightning, there ſhould be two, three, or more conductors, in proportion to the extent of the building.

"In ſhips a chain has often been uſed for this purpoſe, which, on account of its pliableneſs, has been found very convenient, and eaſy to be managed among the rigging of the veſſel; but as the electricity finds a great obſtruction in going through the ſeveral links, for which reaſon chains have been actually broken by the lightning, ſo their uſe has now been almoſt entirely laid aſide; and in their ſtead, copper wires, a little thicker than a gooſe-quill, have been ſubſtituted, and have been found to anſwer very well. One of thoſe wires ſhould be elevated two or three feet above the higheſt maſt in the veſſel; this ſhould be continued down the maſt, as far as the deck, where, by bending, it ſhould be adapted to the ſurface of thoſe parts, over which it may moſt conveniently be placed, and, by continuing it down the ſide of the veſſel, it ſhould be always made to communicate with the water of the ſea."

Another precaution muſt be added to the above directions, which is, that a communication ſhould be made between the conductor, and all other pretty large pieces of metal in the building, ſuch as leaden ſpouts, large iron clamps, &c.; for otherwiſe a lateral exploſion may take place between thoſe detached pieces of metal, at the time that the lightning is conveyed by the conductor, and thence the building may receive ſome damage, though not in a very great degree, unleſs indeed in caſe of powder mills and powder-magazines. See LATERAL EXPLOSION.

It is owing to this circumſtance, that ſome buildings furniſhed with a conductor or two, are ſaid to have been ſtruck and to have been damaged by a ſtroke of lightning. See Phil. Tranſ. vol. lxxii.

The ſize of the conductor, as recommended in the preceding paragraphs, has by ſome been thought too ſmall for the purpoſe; and an inſtance is recorded of a conductor of iron, four inches wide, and half an inch thick, which is ſaid to have been made red hot by a ſtroke of lightning. But with reſpect to this remark, we ſhall briefly obſerve, that ſhould any perſon think that the conductor, as directed above, is not large enough, the enlargement of its ſize is attended with no other inconvenience than an increaſe of expence. However, though a conductor be made red hot, and even melted by a ſtroke of lightning, yet it will effectually convey that ſtroke of lightning to the ground without any material injury to the building, as has been ſufficiently proved by experiments with artificial electricity, as well as with caſes of conductors partly melted by the lightning.

CONDUCTORS *of heat.* When a congeries of bodies remains long in a given degree of temperature, theſe bodies will all acquire the ſame apparent degree of heat; that is, the thermometer placed in contact with any of them, will riſe to the ſame degree; and in this caſe of equilibrium there is no reaſon to believe that any heat, or of caloric, paſſes from one body to another; but if a body, at a certain temperature, be placed amongſt bodies of a different temperature, the caloric will, in this caſe, be communicated from the former to the latter, or *vice verſâ;* according as the temperature of the former is higher or lower than that of the latter. This communication or paſſage of heat from one body to another, is made either by *contact* or by *radiation.*—*By contact*, when the bodies, which are contiguous to the hotter one, are progreſſively heated; *viz.* the neareſt firſt, and then thoſe which are farther off, without any interruption; as when a red-hot piece of iron is placed amongſt other pieces of colder iron, the heat is gradually communicated from the red hot one to the others.—*By radiation*, when the heat from a hot body paſſes through a vacuum, or through tranſparent bodies, which are not heated by it, yet it elevates the temperature of bodies placed at ſome diſtance. Thus, the ſolar heat radiates freely through air, glaſs, water, &c., and heats opaque bodies without ſenſibly affecting the tranſparent bodies through which it paſſes. Thus alſo, a thermometer ſuſpended under the exhauſted receiver of an air-pump, or in the Torricellian vacuum, continues to vary its temperature with that of the ſurrounding bodies.

In the communication of heat from one body to another, when a third body is interpoſed, it has been obſerved that the tranſition of heat is much quicker when certain bodies are interpoſed, than when other bodies are placed between; but there are no bodies known which prevent that tranſition effectually; hence the bodies of the univerſe are diſtinguiſhed into more or leſs perfect conductors of heat, but they afford no inſtance of a perfect non-conductor.

The tranſmiſſion of heat from a ſolid at a higher degree of temperature, to another at a lower one, in a given time, is nearly proportional to the difference of their temperatures. But the velocity with which heat is propagated through the ſubſtance of different bodies, varies conſiderably according to the nature of thoſe bodies. In general, metallic bodies are the beſt conductors of heat; ſtones, or hard earthy bodies come next; then the vitreous ſubſtances, and the reſinous. Dry animal parts, excepting bones, and eſpecially dry and light vegetable bodies, are bad conductors of heat. The conducting power of liquids is of a particular nature, which will be mentioned preſently. But the different bodies of the ſame claſs differ conſiderably in conducting power. Thus the metals poſſeſs it in different degrees, and their proportional powers were thus eſtimated by Dr. Ingenhouſz. He procured equal cylinders of ſeveral metallic ſubſtances, and having coated them with wax, he plunged their extremities in hot water, and judged of the conducting power of each, by the length of the wax-coating that was melted. The reſult of theſe experiments is expreſſed in the following liſt, which commences with the beſt conductors. Journ. de Phyſ. 1789, p. 68.

Silver.

Lead. }

In the ſame paper, the proportional conducting powers of three fluids are ſtated in the following manner:

	Equal bulks.	*Equal weights.*
Water - -	1.	1.
Mercury -	2.	4.8
Linſeed oil -	1.111	1.085

The conducting power of the ſame body does not remain invariably the ſame in all circumſtances; but it differs, according as the body changes its ſtate of exiſtence, ſo that the conducting power of a body in a ſolid ſtate is different from that of the ſame body in a fluid ſtate. And at the time of changing its ſtate of exiſtence, the conducting power in moſt caſes ceaſes altogether. Thus, at the temperature of 60°, ſulphur is a conductor; but when heated to 212°, at which point it melts and becomes volatile, it is no longer a conductor. Thus alſo, ice conducts at the temperature of 20°, or at any other temperature below the freezing point, which is 32°; but at that point it ceaſes to be a conductor, becauſe the heat which may be communicated to it is abſorbed as an ingredient neceſſary to its fluid ſtate, which it aſſumes at, or little above, that point.

Rarefaction or condenſation alters the conducting powers of ſeveral bodies. Yet the rarefaction of air is by no means accompanied with a proportionate diminution of its conducting power.

Profeſſor Pictet ſuppoſes that heat aſcends within ſolid bodies more readily than it deſcends; *viz.* that in communicating heat to a ſolid body by the lateral application of a hotter body, the upper parts of the former are heated ſooner than the lower. This effect, however, may with propriety be attributed to the aſcending current of heated air which riſes along the ſurface of the body, and cauſes colder air to approach the lower part of the body; hence the heat is continually carried upwards.

The conducting power of a body changes likewiſe, in conſequence of an alteration of the ſurface; ſo that poliſh and figure are likewiſe concerned in the reception as well as in the propagation of heat. Theſe particulars, however, together with the reflection and refraction of heat, from the ſurface or through the ſubſtance of bodies, will, with more propriety, be explained under the article HEAT.

Fluids are, upon the whole, very imperfect conductors of heat, and Count Rumford was led, by his experiments, to conclude that heat is not at all propagated through them by contact, as it is in ſolids. (See Rumford's paper on the Conducting Property of Fluid, &c. Phil. Tranſ. 1805.). Whatever permits or promotes the motion of the particles of a fluid, contributes to the propagation of heat;—whatever obſtructs that motion, retards the propagation of heat through them. The particles of air which come in contact with an heated body, being thereby heated and rarefied, become ſpecifically lighter than the ſurrounding air, and of courſe aſcend; other air then comes in contact with the heated body, and this alſo being heated is cauſed to aſcend, and ſo forth. Thus is heat conveyed from the original hot body, by the air, to a diſtance from it; but if that motion of the air be obſtructed, as by the interpoſition of partitions of paper, wool, cotton, furs, and the like, then the communication of heat is prevented more or leſs effectually. It is principally on this account, that furs, feathers, eider down, cotton, and other ſimilar things, form warm coverings; *viz.* becauſe, by preventing in great meaſure the motion of the air between their filaments, they prevent at the ſame time the diſſipation of heat.

The like obſervations are applicable to water, and perhaps to all other fluids. When a veſſel full of water is ſet upon the fire, the particles of water that are cloſe to the bottom of the veſſel are firſt heated and rarefied; in conſequence of which they aſcend, and other colder particles take their place, which, being heated, likewiſe aſcend, and ſo on. If the fire be applied to the upper part of the water, the fluid will not be heated, or at moſt it will in a very ſlight degree. Count Rumford (ſee his 7th Eſſay) confined a piece of ice at the bottom of a pretty tall glaſs veſſel full of water nearly boiling, and noted the time it took up to melt the ice. The experiment then was repeated with this difference, *viz.* that a ſimilar piece of ice was placed on the ſurface of the hot water, inſtead of the bottom. It was found that the ice melted more than eight times quicker in this laſt ſituation than in the former. The reſult of this remarkable experiment is explained in the following manner. When the ice ſwims on the ſurface of the hot water, the particles of the latter, that are contiguous to the ice, being cooled by it, deſcend, and other hot particles of water take their place, which depoſit their heat upon the ice, and, being thereby rendered ſpecifically heavier than the next particles of watert alſo deſcend, and ſo forth. But when the ice is confined a, the bottom of the veſſel, the particles of hot water which come firſt in contact with it, are cooled, and are rendered ſpecifically heavier, in conſequence of which they remain in their place, and no motion will take place within the water; hence the ice is not melted nearly ſo readily as in the former ſituation. Now count Rumford contends that it is by means of the above-mentioned motion only that heat is propagated through fluids, and not otherwiſe. This concluſion was no ſooner publiſhed to the ſcientific world, than it was oppoſed in an able manner by very ſkilful philoſophers. See Dalton's paper. Nich. Journ. vol. iv. p. 75. Traill's paper, ibid. for 1805, p. 133: and Murray's paper, ibid. vol. i. From theſe papers we ſhall make the following abridged extracts, which ſeem neceſſary for the elucidation of the ſubject; and in the firſt place we ſhall ſtate Mr. Murray's experiments.

Into a glaſs cylindrical veſſel water was poured, till it covered the bulb of a thermometer; its temperature was 46°, which was likewiſe the temperature of the air of the room. One ounce of olive oil, heated to 140°, was poured on a ſmall piece of cord, ſuſpended on the ſurface of the water, and the cord was ſlowly withdrawn. Any motion of the water was thus avoided. In the courſe of a minute the thermometer began to riſe ſlowly; in five minutes from the commencement of the experiment, it had riſen 4°, in ten minutes $6\frac{1}{2}$°, in fifteen minutes 8°. It then became ſtationary, and continued ſo for ſeven minutes, before it began to fall. Its deſcent was ſlow. This experiment was repeated with a hot metallic ball (inſtead of oil) immerſed in the water above the thermometer, and it was attended with a ſimilar effect.

From theſe reſults the concluſion might ſeem juſt, that the fluid muſt poſſeſs a conducting power. Yet this is rendered doubtful by the circumſtance, that in all experiments of this kind, a quantity of caloric muſt be conveyed by the ſides of the veſſel. In order to avoid this ſource of error, Mr. Murray employed a veſſel of ice. But water could not be uſed in this caſe, becauſe that fluid expands from 40° to 32°; therefore oil and mercury were uſed.

A quantity of almond oil was poured into the ice veſſel, ſo as to cover the bulb of the thermometer a quarter of an inch. A ſmall cylindrical iron cup, two inches in diameter, and having a flat bottom, capable of holding two ounces by meaſure, was ſuſpended ſo as merely to touch the ſurface of the oil, and was filled with boiling water. At the beginning of the experiment, the thermometer ſtood at 32°. In a minute and a half it had riſen to $32\frac{3}{4}$°, in three minutes to $34\frac{1}{2}$°, in five minutes to $36\frac{1}{4}$°, in ſeven minutes to $37\frac{1}{2}$°. At this point it became ſtationary, having riſen $5\frac{1}{2}$° in ſeven minutes. The temperature of the water in the cup had in this time fallen to 96°. The thermometer, after remaining ſtationary at $37\frac{1}{2}$° for ſix minutes, began to fall, and it continued to deſcend at the rate nearly of a degree in a minute and a half, till it returned to 32°. The experiment was repeated with this variation, *viz.* that the thermometer was placed lower, ſo that half an inch of oil ſtood over its bulb. It was alſo repeated with mercury inſtead of oil. But in both caſes the reſults were ſimilar to that of the firſt experiment.

"This riſe," Mr. Murray ſays, "it appears to me impoſſible to aſcribe to any other cauſe than to a power in the fluid to conduct caloric. Thus it is evident, that the ſides of the veſſel could not convey to the fluid in contact with the bulb of the thermometer any part of the caloric it received. Ice, in common with any other ſolid, may, at temperatures below its melting point, conduct caloric; but as it cannot poſſibly exiſt with a temperature above 32°, it cannot communicate any temperature above that to a fluid in contact with it, and conſequently it could not contribute in the above experiment to raiſe the thermometer above that temperature. Caloric does not radiate through tranſparent fluids, and it cannot even be ſuppoſed capable of paſſing by radiation through an opaque fluid as mercury.

If it be proved that oil and mercury are capable of conducting caloric, it will be admitted as ſufficiently probable, that other fluids may have a ſimilar power. Of theſe two, mercury, it is probable from theſe experiments, is the beſt conductor, as the riſe of the thermometer took place in it much more rapidly than in the oil."

Dr. Traill's experiments for aſcertaining the conducting powers of divers fluids, were performed in the following manner.

A cylindrical veſſel was turned out of wood, having its ſides half an inch thick, its height four inches and its diameter two. It has a moveable wooden top or cover, perforated with a hole in its centre, a little more than an inch in diameter, into which an iron cylinder, of one inch in diameter, could be eaſily introduced. This cylinder is ſupported by a ſlight flanch, or ſhoulder-piece, and can be taken up by means of a ſtring attached to its top. When the iron bar is in its place, its flat lower extremity is half an inch diſtant from the bulb of a delicate mercurial thermometer, which is fixed by wax in a hole perforating the cylinder near its bottom. This thermometer is bent to a right angle, ſo that its bulb and part of its ſtem lie in the axis of the wooden cylinder. This ſhape was preferred, becauſe the ſtem could be little affected by the caloric tranſmitted by the ſides of the veſſel, till after the bulb was acted on by the caloric of the iron bar.

A variety of experiments was performed with this apparatus in the following manner: The temperature of the room being ſteadily 67°, Fahren. therm.; during the trials, a kettle of water was kept boiling over the fire. Its temperature was between 211° and 212°, and in this the cylinder of iron was ſuffered to remain, at each experiment, for fifteen minutes. The liquid to be examined, and all the apparatus (but the iron bar) were at each experiment aſcertained to be at 67°. The liquid was poured into the wooden veſſel, till it could riſe $\frac{1}{10}$ of an inch on the ſide of the iron cylinder when in its place. The wooden top was put on, and the iron was drawn out of the kettle of boiling water by means of the attached ſtring, and inſtantly let down through the hole of the cover. The time the thermometer took to riſe through 3° (*viz.* from 67° to 70°) was accurately marked by means of a ſtop-watch, and the reſults of the experiments on ſeveral fluids, are exhibited in the following table.

Liquids.	Minutes.	Seconds.
Water - - - -	7	5
Cow-milk - - - -	8	25

Saturated ſolution of ſulphate of alumine -	9	40
Saturated ſolution of ſulphate of ſoda -	6	30
Aqua potaſſ. pura. London Pharm. -	8	15
Saturated ſolution of ſulphate of ſoda, but the liquid not touching the iron cylinder, by $\frac{1}{10}$ of an inch, or nearly ſo -	19	20

"If I am not deceived," ſays Dr. Traill, "we may conclude, from what I have above adduced, that liquids, as well as ſolids, are conductors of caloric; that the tranſmiſſion of it through them follows a particular law depending on the properties of the particular liquid; but which is not in the exact ratio of any of their mechanical properties, though nearer that of their denſity, than any other."

A circumſtance, deſerving the attention of the ſpeculative philoſopher, reſpecting the conductors of electricity and of heat, has been obſerved; *viz.* that moſt of thoſe bodies which are good conductors of the one, are likewiſe good conductors of the other. This law, however, is not without exceptions. Thus, metallic bodies are good conductors of both; but charcoal is a good conductor of electricity, though a very bad conductor of heat.

The laſt particular, which we ſhall briefly notice, with reſpect to the conductors of heat, is their uſe. This, on the leaſt examination, will be found to be very extenſive. Nature and art avail themſelves of theſe peculiar properties of bodies, and without them both animal and vegetable life could not ſubſiſt. The atmoſpherical fluid which envelopes the earth, is a very bad conductor of heat, undoubtedly created for the purpoſe of not diſſipating the heat of the earth and terreſtrial bodies. The coverings of animals, ſuch as furs and feathers, being extremely bad conductors, confine the heat on the animal body. The bark and ligneous part of plants, in conſequence of their imperfect conducting powers, tend to prevent the freezing of vegetable juices. The induſtry of man has not omitted to uſe the worſt conductors of heat for coverings, for the defence of his habitations, for the confinement of heat in certain furnaces, &c. In ſhort, numerous and admirable effects are deduced by Providence, and ſeveral eſſential advantages are obtained by art, from a proper application of the various conducting powers of natural bodies.

CONDUCTORS, in the *Military Art*, are aſſiſtants to the commiſſary of ſtores in conducting depots and magazines from one place to another. They take charge of the ammunition waggons in the field, make their reports to the commiſſary, and are under his authority and command.

CONDUCTOS *ad proficiſcendum*, in *Law*. See CAPIAS.

CONDUIT, a canal, or pipe, for the conveyance of water, or other fluid matter.

In the earth are ſeveral ſubterraneous conduits, through which the waters paſs that form ſome SPRINGS; and through which alſo paſs the vapours which form METALS and MINERALS.

Artifical conduits for water are made of lead, ſtone, caſt iron, potter's earth, &c. See PLUMBERY.

In the province of New Mexico, there is ſaid to be a ſubterraneous conduit, in form of a grotto, extending ſix hundred miles in length. See DUCT, TUBE, &c.

CONDUITE *d'une Troupe.* A *troop* that marches has always an officer, who commands independently of the other officers that may accompany it.

CONDUSKEEG, in *Geography*, a ſettlement of America, in the diſtrict of Maine and Hancock county, containing 567 inhabitants.

CONDYLÆ, in *Ancient Geography*, a town of Arcadia, near Caphia, and N.W. of Orchomenæ. In this town was a temple of Diana, and near it a grove. Pauſanias.

CONDYLE, in *Anatomy*, an appellation beſtowed on ſeveral projections of the bones.

CONDYLOMA, from κόνδυλος, *digiti articulus*, in *Surgery*. By this term is underſtood almoſt every hard excreſcence or ſarcoma, that appears in the parts about the anus and the pudenda of both ſexes; which is generally painful, or at leaſt troubleſome, and ſometimes of a venereal origin. According to the different forms which ſuch excreſcences aſſume, they are termed *condylomata, fici, cristæ, verrucæ, framboeſiæ, &c.*; however they do not materially differ, being all of the ſame nature, and requiring the ſame mode of treatment. They are diſtinguiſhed from the hæmorrhoids by their ſituation, irregular form, the conſtant preſſure which they produce, their generally fungous texture, and the foul matter which is frequently diſcharged from their ſurface, or by the venereal ſymptoms with which they are accompanied. In ſome caſes they are not harder than the parts upon which they are ſituated; ſometimes, however, they are harder than the moſt complete ſcirrhus. With reſpect to their colour, they are, in ſome caſes, of a pale white, in others more or leſs red. Sometimes they are found ſingle; but generally the whole of the parts about the anus becomes covered with them. Frequently they are not larger than common warts; which, when the diſeaſe has proceeded to a great height, become more numerous, and adhere to or are in contact with each other. In other caſes, theſe excreſcences are from the beginning broad and flat, and frequently of the ſize of a large bean ſplit in half. Sometimes they hang, like figs, on a ſlender ſtalk. Theſe excreſcences are in general more troubleſome than dangerous; however, the ſyphilitic virus by which they may have been produced is what is moſt to be feared.

In the cure of theſe excreſcences, the principal object is to remove the cauſe, eſpecially when of a venereal kind; and they are either local affections, or, which is ſometimes the caſe, effects of a depraved ſtate of the body. After the appropriate internal remedies (ſee SYPHILIS) have been adminiſtered, they frequently dry up of themſelves, and when they remain, they muſt be treated with topical corroſive applications. When theſe excreſcences are of a ſofter conſiſtence, and their ſurface ſore or ulcerated, we may mix Aq. calcis. with Spir. vin. Camph. and Tinct. myrrhæ, and apply this mixture ſeveral times a day to the excreſcences, by means of a hair-pencil, or cover them with compreſſes dipped in it. Still greater effects are produced by the fine powder of ſavine ſprinkled frequently upon them; this powder may alſo be mixed into an ointment with precipitate of mercury, and ſpread upon the excreſcences. Or they may be ſprinkled once or twice a day with the powder, and a ſaturnine cerate with opium afterwards applied. In various caſes, the following corroſive waſh of Mr. Plenk has been found the moſt effectual remedy: ℞. Spir. Vin. rect. Acet. vin. concentrat. aā ℥ſs. Merc. ſubl. corroſiv. ʒj. Alum. crud. Camph. Ceruſs. aā ʒſs. M. D. S. To be rubbed twice or thrice a day upon the excreſcences, which are to be covered during the intervals with Ungt. ex Hydrargyro.

Frequently the excreſcences diſappear without ſuppurating, and the ſound ſkin is not injured. Mercurial fumigations with cinnabar are likewiſe recommended as powerful remedies. The aqua phagedænica has ſometimes been found very effectual in removing very ſmall venereal warts.

If the excreſcences do not yield to the uſe of any of theſe remedies, but remain hard, callous, and fungous, we may apply the following: Triturate Merc. ſublim. corroſiv. ʒſs. in a marble mortar, and add gradually Spir. nitr. fumant. ℥ſs. The application of this remedy, which is to be applied every day, or every other day, muſt be performed with the utmoſt caution, by means of a hair-pencil, with which it is to be rubbed upon the ſummit of the excreſcence. We may alſo employ the *lunar cauſtic,* alſo the *lap. infern.* or Butyr. antimon., which are likewiſe to be applied in a very cautious manner; and we ought particularly to take care not to let any part of them come into contact with the rectum, which would produce very dangerous conſequences. The extirpation by means of ligatures may be employed when the number of the excreſcences is but ſmall, and they hang by ſmall ſtalks to the ſurface; for otherwiſe it is a painful remedy. The moſt certain method of removing them is by means of the knife, only they frequently grow again within a ſhort time; nor ought this remedy to be employed in venereal caſes, till a ſufficient quantity of mercury has been adminiſtered. In cutting them off, all the adjacent diſeaſed parts muſt be taken away; and in order to prevent inflammation, the blood may be ſuffered to flow for ſome time, after which the parts may be covered with lint, and treated as a common wound.

CONDYLON, in *Ancient Geography*, a fortreſs of Greece, between Connas and Tempé, towards Theſſaly.

CONE, in *Geometry*, a ſolid body, having a circle for its baſis, and terminated at the top in a point, or vertex. See *Plate* I. *Conics*, *fig.* 4.

The cone is generated by the motion of a right line, KM, round an immoveable point, K, called its *vertex*, along the circumference of a plane, called its *baſe*, MN: or it may be conceived as generated by the revolution of the triangle, KLM, about the right line, KL, which is called the *axis* of the cone, and KM its latus or ſide. If the axis be perpendicular to the baſe, it is ſaid to be a *right* cone: and if inclined, or oblique, an *oblique* or *ſcalenous* cone. *Scalenous* cones are again divided into *obtuſe-angled*, and *acute-angled*.

An *equilateral* cone, is a right cone, whoſe ſide is equal to the diameter of the baſe.

Euclid defines a cone a ſolid figure, whoſe baſe is a circle, as CD (*fig* 5.), and is produced by the entire revolution of the plane of a right-angled triangle CAB, about the perpendicular leg AB.

If this leg, or axis, be greater than CB, half the baſe, the ſolid produced is an *acute-angled* cone; if leſs, it is an *obtuſe angled* cone; and, if equal, a *right angled* cone.

But Euclid's definition only extends to a *right* cone; that is, to a cone whoſe axis is at right angles to the baſe; and not to oblique ones, whoſe axis is not at right angles to the baſe.

For a more general and comprehenſive deſcription of a cone, which may take in both right and oblique ones, ſuppoſe an immoveable point A (*fig.* 6.), without the plane of the circle BDEC; and ſuppoſe a right line, AE, drawn through that point, and produced infinitely both ways, to be moved quite about the circumference of the circle; the two ſuperficies that will ariſe from this motion are each called *conic ſuperficies*; but, taken conjunctly, they are called *ſuperficies vertically oppoſite*, or only *oppoſite ſuperficies*. The immoveable point, A, common to both the ſuperficies, is called the *vertex*; the circle BDEC, the *baſe*; the right line AC, drawn through the vertex A, and C, the *centre of the baſe*, and if infinitely produced, the *axis*; and the ſolid, comprehended under the conical ſuperficies and the baſe, is a *cone*.

Cone, *Properties of the.*—1. *The area or ſurface of every right cone, excluſive of its baſe, is equal to a triangle whoſe baſe is the periphery, and its height the ſlant ſide of the* cone.

Take the very ſmall arc IK (*fig.* 7.), and draw AI, AK. Then the part of the ſurface AIK coincides with the ſmall iſoſceles triangle AIK, whoſe baſe is IK, and height AI. In like manner, the whole ſurface of the cone may be ſuppoſed to conſiſt of ſuch triangles whoſe common height is AI, and baſes ſo many KI's as are contained in the circumference of the baſe, all which triangles are equal to the triangle whoſe height is AI, and baſe, the ſum of all the KI's, or the circumference BKDB. Hence, the curve ſurface of a right cone is equal to half the rectangle of the ſide AB, and circumference of the baſe, BKDB. For the half of that rectangle is equal to a triangle of the ſame baſe and height. Moreover, the curve ſurface of a right cone is equal to a circle, whoſe radius is a mean proportional between the ſide AB, and the radius of the baſe BC. For the conic ſurface is $= \frac{AB \times BKDB}{2}$, and the area of the baſe $BD = \frac{BC \times BKDB}{2}$ (ſee Circle). Let the radius, R, repreſent the mean proportional between AB and BC, or let $R = \sqrt{AB \times BC}$; and the area of the circle whoſe radius is $R = A$. Then the conic ſurface : circle BD :: $\frac{AB \times BKDB}{2} : \frac{BC \times BKDB}{2}$ :: AB : BC :: $AB \times BC : BC^2$; and the circle BD : circle A :: $BC^2 : R^2$ or $AB \times BC$: conſequently the conic ſurface : circle A :: $AB \times BC : AB \times BC$, which is a ratio of equality: therefore the conic ſurface = circle A, whoſe radius is $\sqrt{AB \times BC}$. Hence alſo, the curve ſuperficies of a right cone is to the area of its circular baſe, as AC (*fig.* 5.), the length of the hypothenuſe of the right-angled triangle deſcribing it, is to CB, the baſe of the ſame triangle: that is, as the ſlant ſide of the cone, to the ſemidiameter of the baſe.

Hence alſo, the ſurface of a right cone is equal to a ſector of a circle deſcribed on the ſlant ſide of the cone, as a radius, whoſe arc is equal to the periphery of the baſe of the cone: and has therefore the ſame proportion to its periphery, which the diameter of the baſe has to twice the ſide of the cone. *Hence we have a method of deſcribing a rete or cage that ſhall juſt cover a* cone.—Thus, with the diameter of the baſe AB (*Plate*, *Conics*, *fig.* 8.), deſcribe a circle, and produce the diameter to C, till AC be equal to the ſide of the cone. To 2 AC and AB, determined in numbers, and 360°, find a fourth proportional: and with the radius CA, on the centre C, deſcribe an arc DE equal to the number of degrees found: the ſector CDE with the circle AB will be a rete for the right cone.

If, then, the ſide of a truncated cone be ſet off from A to F, and an arc GH be deſcribed with the radius CF; by finding a fourth proportional to 360°, to the number of degrees of the arc GH, and to FC; and thence determining the diameter of the circle IF, we ſhall have a net or cover of the truncated cone.

For CDBAE is a net for the entire cone; CGFIH for the cone cut off; therefore, DBEHIG for the truncated cone.

2. *Cones and pyramids, having the ſame baſes and altitudes, are equal to each other.*

Now, it is ſhewn, that every triangular priſm may be divided into three equal pyramids; and therefore, that a triangular pyramid is one third of a priſm, ſtanding on the ſame baſe, and having the ſame altitude.

Hence, ſince every multangular body may be reſolved into triangular ones, and every pyramid is a third part of a priſm, having the ſame baſe and altitude; ſince a cone may be eſteemed an infinite-angular pyramid, and a cylinder an infinite-angular priſm; a cone is a third part of a cylinder, which has the ſame baſe and altitude. Hence, cones of equal baſes are as their heights; cones, and alſo fruſtums of cones, of equal altitudes, are as the baſes: cones are to one another in the compound ratio of the baſes and heights: and in equal cones, the baſes and heights are reciprocally proportional.

Hence we have a method of meaſuring the ſurface and ſolidity of a cone. Thus, *for the ſolidity:* find the ſolidity of a priſm, or cylinder, having the ſame baſe with the cone, or pyramid, or, multiply the baſe by the altitude: then divide by 3: the quotient will be the ſolidity of a cone, or a pyramid. Thus, *v. gr.* if the ſolidity of a cylinder be 605592960, the ſolidity of the cone will be found 201864320.

For the ſurface; that of a right cone is had by multiplying the ſemi-periphery of the baſe into the ſide, and adding the product to the baſe.

All cones, which have their altitudes and the diameters of their baſes reciprocally proportional, are in the triplicate ratio of their altitudes, being to each other in the ſame proportion with priſms of equal baſe and altitude, of which they are like parts. See Prism.

Suppoſe, *e. gr.* the diameter of the cone NM (*fig* 4.) 56, the periphery will be 175,9296, and the baſe 2463,0144. Suppoſe the altitude or axis KL, 246; ſince $LM = \frac{1}{2} NM = 28$, and $KM^2 = KL^2 + LM^2 = 60516 + 784 = 61300$, $KM = 247{,}5$, &c. Conſequently the ſuperficies of the cone, excluſive of the baſe, is 21771,288; and the whole together 24234,3024.

The ſolidity of an oblique cone is obtained in the ſame manner with that of the right cone: but it is much more difficult to find its ſurface, ſince it cannot be reduced to the meaſure of a ſector of a circle, becauſe all the lines drawn from the vertex to the baſe are not equal. See a Memoir on this ſubject, by M. Euler, in the Nouv. Mem. de Peterſburgh, tom. i. Dr. Barrow has demonſtrated, in his Lectiones Geometricæ, that the ſolidity of a cone with an elliptic baſe, forming part of a right cone, is equal to the product of its ſurface by a third part of one of the perpendiculars drawn from the point in which the axis of the right cone interſects the ellipſe; and that it is alſo equal to one third of the height of the cone multiplied by the elliptic baſe: and therefore that the perpendicular is to the height of the cone, as the elliptic baſe to the ſurface.

For the meaſure of the ſurface, and ſolidity of a truncated cone, or *fruſtum*, ABCD (*fig.* 8). Its altitude CH, and the diameters of its baſes AB and CD, being given, find their circumferences; to the ſquare of the altitude CH, add the ſquare of the difference of the radii AH, and from the aggregate extract the ſquare root, which will give the ſide AC: the ſemi-ſum of the peripheries, multiplied by that ſide, gives the ſuperficies of the truncated cone or fruſtum.

To find the ſolidity: as the difference of the ſemi-diameters AH, is to the altitude of the truncated cone or fruſtum CH, ſo is the greater ſemi-diameter AF to the altitude of the entire cone FE. This being found, ſubtract the altitude of the truncated cone GF, which will leave that of the cone taken off, EG.

Find the ſolidity of the cone CED and AEB; ſubtract the other from this; the remainder will be the ſolidity of the truncated cone or fruſtum ACDB. Or, add into one ſum the areas of the two ends of the fruſtum and the mean proportional between them; multiply that ſum by the perpendicular height, and $\frac{1}{3}^{d}$ of the product will be the ſolidity. For the method of finding the ſurface and ſolidity of a cone, &c. by fluxions; ſee Superficies and Solidity.

Cone, *Ungula of.* See Ungula.

For the ſections of the Cone, ſee Conic *ſection.—For the ratio of* Cones *and Cylinders*, See Cylinder.—*For the centres of gravity and of oſcillation of a* Cone, ſee Center.

Cones *of the higher kinds*, are thoſe whoſe baſes are circles of the higher kinds; and are generated by ſuppoſing a right line fixed in a point, on high, though conceived capable of being extended more or leſs, on occaſion; and moved or carried round the ſaid circle of the higher kind.

Cone *of rays*, in *Optics*, includes all the ſeveral rays which fall from any point of a radiant, on the ſurface of a glaſs.

Cone, *double*, or *ſpindle*, in *Mechanics*, is a ſolid formed of two equal cones joined at their baſes. If this be laid on the lower part of two rulers making an angle with one another, and elevated above the horizontal plane, it will move towards the raiſed ends, and ſeem to aſcend, though it really deſcends. Let ABD (*Plate* XVI. *Mechanics, fig.* 7.) be the common baſe of the two cones, its centre C will be the centre of gravity of the whole ſolid: therefore, if DF repreſents one of the rulers elevated to an angle FDG, whoſe ſine FG is leſs than the ſemidiameter of the cone CD, it is plain that the centre of gravity C at the poſition of the cone in D, is more diſtant from the centre of the earth, to which all heavy bodies tend, than in its poſition between the legs of the ruler at F; and therefore it will deſcend, as on an inclined plane CFE, from C to F, where it will ſtop, being ſupported on the raiſed ends of the rulers.

Cone, in *Aſſaying*. See Melting-*cone*.

Cone, in *Botany*, a hard dry ſeed-veſſel of a conical figure, conſiſting of ſeveral woody parts; and is, for the moſt part, ſcaly, adhering cloſely together, and ſeparating when ripe.

Cone-*ſtone*, in *Natural Hiſtory*, the name given by many to a ſpecies of tubulus *marinus*, not known to us in its recent ſtate, but frequently found foſſile in the Swediſh ſtones uſed in pavements.

Cone *and key*. Bracton, lib, ii. cap. 37. num. 3. ſays, *Fæmina in tali ætate* (*i. e.* 14. *et* 15. *annorum*) *poteſt diſponere domui ſuæ, et habere* cone *et* key.

The words come from the Saxon *colne*, i. e. *calculus*, and *key*, *clavis;* ſo that a woman was then held to be of competent years when ſhe was able to keep the accounts and keys of the houſe: and Glan. lib. vii. cap. 9. has ſomewhat to the ſame purpoſe.

Cone, in *Conchology*. See Conus.

CONECTE, Thomas de, in *Biography*, a monk of the order of the Carmelites, born in Bretagne, towards the cloſe of the fourteenth century, and diſtinguiſhed as the moſt popular and impreſſive preacher of his time. In his diſcourſes he did not confine himſelf to ſubjects of religion and morality, but he attacked with vehemence the reigning follies and faſhionable foibles of the age. The head dreſs of the ladies in particular was the ſubject of his repeated remonſtrances. At this period, ſays Bayle, "the head-dreſſes were of ſuch a prodigious height, that the higheſt top-knots now are but dwarfs to them." Conecte reformed that exceſs, and obliged the ladies to dreſs themſelves modeſtly and with a ſtrict regard to decorum. It was not, however, ſo much by the force of the reaſons with which he repreſented the evangelical duties, as by exciting boys and the commonalty to inſult thoſe of the other ſex, who would not introduce a reform into their dreſs. Whether, however, he aimed at vice or folly, he was ſo famed as an orator, that no churches were ſufficiently ſpacious to contain the crowds, that followed him wherever he went; he therefore choſe as theatres for the diſplay of his eloquence, public ſquares and other places where immenſe ſcaffolds were erected, from which he could make himſelf heard by many thouſands at the ſame time. When he travelled from place to place, it was on a mule attended with many monks and prieſts on foot. As ſoon as he arrived in the vicinity of any town, the moſt conſiderable perſons for rank and property came out to meet him, in order to conduct him to the houſe provided for his lodging, which was commonly the beſt in the place. His labours were not confined to his own country; from France he proceeded to the Netherlands, and Italy, exciting every where the ſame attention which he experienced in his native land. At Venice he gained ſo much reputation, that the embaſſadors from that republic to the pope, invited him to accompany them to Rome. But the freedom and aſperity of his declamations againſt the corruption of the clergy and the court, rouſed the reſentment, and paſſions of the papal ſee; he was accordingly tried and condemned for hereſy, and burnt at Rome in the year 1434. His motives were queſtioned by ſome of his contemporaries, but the readineſs with which he ſubmitted to a cruel death, in defence of his conduct, rather than retract the charges which he had exhibited againſt the profligacy of the Romiſh hierarchy, was ſufficient evidence of his ſincerity in a good cauſe. Bayle.

CONEGLIANO, Gio Batista Cima, called *Il*, from the place of his nativity, a ſmall city in the ſtate of Venice, became, under the tuition of Giovanni Bellini, a painter of conſiderable eminence; and indeed ſo entirely did Conegliano poſſeſs himſelf of the ſtyle of Bellini, that the works of the ſcholar are frequently confounded with thoſe of the maſter; even by good judges. It was however much the cuſtom with the older Venetian painters to ſubſcribe their names to their works; many therefore of this artiſt are ſtill known, as well by the inſcription as by the mountainous view of the town of Conegliano with which he uſually enriched his back grounds. A juvenile performance of this maſter with the date 1493, is in the duomo of Conegliano: a more excellent picture by him is in the church of Santa Maria dell' Orto, at Venice. It repreſents St. Peter, St. Paul, St. Mark, and St. Jerome, with a magnificent architectural back-ground. But in the opinion of Lanzi, the chef-d'ouvre of Conegliano is an altar-piece in the duomo at Parma, the ſubject of which however he has neglected to mention. This maſter is ſuppoſed to have died ſhortly after 1517. Lanzi. Storia Pittorica. Zanetti, Pittura Veneziana.

CONEGOCHEAQUE Creek, in *Geography*, a creek of America, which riſes near Marierſburg, in Franklin county and ſtate of Pennſylvania, runs ſoutherly in a winding courſe, and after ſupplying a number of mills, diſcharges itſelf into the Potowmack at William Port, in Waſhington county, Maryland; 19 miles S.E. of Hancock, and 8 miles S. of the Pennſylvania line.

CONEI or Cowne, George, a native of North Britain, and a zealous catholic, went to reſide at Modena, in Italy, at an early age. He afterwards ſettled at Rome, and was celebrated, during the pontificate of pope Paul V., for his profound knowledge of the Greek and Latin languages. His own good character recommended him to the patronage of the cardinals Montalto and Barberini. The latter being nephew to pope Urban VIII., Conei ſoon obtained ſo much of the favour and confidence of the pontiff as to be entruſted with the office of nuncio to Maria Henrietta, queen of England, which he diſcharged completely to the ſatiſfaction of the papal court. As a reward for his conduct he would have been raiſed to the dignity of cardinal, had not death cut off his proſpects. He died in 1640, at the age of forty-two; leaving behind him, among other works of merit, "The Life of Mary Stuart;" "De Inſtitutione principis;" "De Duplici Statu Religionis apud Scotos," &c. &c.

CONEMAUGH River, and *Little Conemaugh*, in *Geography*, are the head waters of Kiſkemanitas, in Pennſylvania. After paſſing through Laurel hill and Cheſnut ridge, Conemaugh takes that name, and diſcharges itſelf into the Alleghany, 29 miles N.E. of Pittſburgh. It is navigable for boats, and there is a portage of 18 miles between it and the Frankſtown branch of Juniata river.—Alſo, a town of Pennſylvania, 15 miles E. of fort Ligonier.

CONENTOS, Las, a city of La Plata or Paraguay, in South America, in the dioceſe of Buenos Ayres.

CONEPATL, in *Zoology*, an American animal of the weeſel kind mentioned by Hernand.; and alſo by Ray under the title of *Yzquipatl*. It is deſcribed as bearing a ſtrong reſemblanee to the racoon in ſhape, but variegated with two long ſtreaks of white, one on each ſide of the ridge of the back, which run even into the tail. This animal is ſaid to be of a harmleſs diſpoſition, but of a ſtinking ſmell, and when purſued, or provoked, will diſcharge its excrements at the perſon who offends it to ſix or eight feet diſtance; theſe have a very bad ſmell and ſpoil peoples cloaths by leaving indelible yellow ſpots on them. Little more is known of this animal than is above related. It inhabits New Spain, and was placed by Linnæus in his Syſtema as the ſame ſpecies with his Viverra Memphitis, the memphitic weeſel, and chinche of Buffon. Gmelin conſiders it as a diſtinct ſpecies, and deſcribes it ſpecifically under the name of conepatl. This animal may prove to be a variety only of the ſtriated weeſel, or perhaps only of the memphitic weeſel to which Linnæus at firſt aſſigned it. See Viverra.

CONERFREIT, in *Geography*, a town of Germany, in the circle of Bavaria, and Upper Palatinate; 34 miles N.N.E. of Amberg.

CONESSI, or Conesti, in the *Materia Medica*, a bark brought from the Eaſt Indies. It is frequent in Ceylon, and Malabar, where the natives take it in diarrhœas, lienteries, and dyſenteries. We uſe it in powder for the ſame purpoſes, the doſe being from half a dram to a dram. It is proper to give a doſe of ipecacuanha before taking it.

This tree grows alſo on the Coromandel coaſt, in the Eaſt Indies, and is not unlike the *cadagopala* of the *hortus Malabaricus*. The bark ſhould be freſh powdered, and the electuary prepared with ſyrup of oranges every day or every other day. Med. Eſſ. vol. iii. art. 4.

CONESTEO, in *Geography*, a north-weſtern branch of Tioga river in the ſtate of New York, America.

CONESTOGA, a townſhip of America, in the county of Lancaſter and ſtate of Pennſylvania.

CONESUS, a ſmall lake of America, in the county of Geneſſee and ſtate of New York, which conveys its waters N.W. to Geneſſee river.

CONFARREATION, a ceremony among the ancient Romans, uſed in the marriage of perſons whoſe children were deſtined for the honour of the prieſthood.

Confarreation was the moſt ſacred of the three modes of contracting marriage among that people; and conſiſted, according to Servius, in this, that the *pontifex maximus* and *flamen dialis* joined and contracted the man and woman, by making them eat of the ſame cake of ſalted bread; whence the term, *far* ſignifying meal or flour.

Ulpian ſays, it conſiſted in the offering up of ſome pure wheaten bread; rehearſing, at the ſame time, a certain formula, in preſence of ten witneſſes. Dionyſius Halicarnaſſeus adds, that the huſband and wife did eat of the ſame wheaten bread, and threw part on the victims.

CONFECTION, in *Pharmacy*, a kind of compound remedy, of the conſiſtence of a ſoft electary, or electuary.

Confections and electuaries are compoſed chiefly of powders, mixed up with ſyrups or honey, into ſuch a conſiſtence, that the powders may not ſeparate by keeping. They are chiefly the milder medicines, and ſuch as are not very ungrateful to the palate, that enter into the compoſition of the electuaries; for as they are taken ſomewhat "ad libitum," it would be unſafe to truſt this mode of exhibition of the more active drugs. The lighter powders require about twice the weight of ſyrup to be brought to the proper conſiſtence of an electuary. The ordinary doſe is a piece about the bulk of a nutmeg. See Electuary.

Several electuaries were formerly diſtinguiſhed by the name of confections; ſome of which, in the medical language, are *corroborative*, and others *purgative*.

Of the number of the corroborative confections, were thoſe of *alkermes*, of *hyacinth*, and the *anacardine:* a purgative one is the confection *Hamech*. The confection of *alkermes* has its name from the principal ingredients therein; which is the *kermes*, or *alkermes*, or ſcarlet-grain. The other ingredients were pearls, muſk, cinnamon, ambergris, leaf-gold, juice of pippins, and roſe water. It was ranked among the beſt cardiacs, and frequently uſed for the palpitation of the heart, or ſyncope; and ſometimes in the ſmall-pox and meaſles.

The confection of *hyacinth* was ſaid to have nearly the ſame virtues with that of *alkermes;* but, beſides, it was frequently uſed as an aſtringent. It conſiſted of nearly triple the number of drugs; whereof the precious ſtone, called the *hyacinth*, was eſteemed the principal; the chief of the reſt were, red coral, bole armoniac, terra ſigillata, myrrh, the ſantals, burnt hartſhorn, camphire, ſapphire, emerald, topaz, and moſt of the ingredients of the confection of alkermes. The *anacardine* confection was compoſed chiefly of anacardiums; whence the name. The other drugs were long pepper, black pepper, moſt kinds of myrobalans, caſtoreum, &c. It was uſed to purge the blood, and deemed proper in cold diſeaſes.

The confection *Hamech*, took its name from that of its inventor, an Arabian phyſician. Its ingredients were, polypody, myrobalans, agaric, ſenna, tamarinds, red roſes, manna, colocynth, &c. It was applied as a draſtic for the purging of the groſſer humours and viſcidities; it was alſo of ſome reputation in vertigoes and cancers. But all theſe, though we have thought it proper to mention them, are excluded from the modern diſpenſatories.

CONFECTIO *aromatica*. See the next article.

Confectio *cardiaca*, a name given in the late London Diſpenſatory to the ſo much eſteemed medicine commonly known by the name of the *confectio Raleighana*, and now denominated *confectio aromatica*. The compoſition is alſo altered, as well as the name, and is ordered now to be made in the following manner: Take zedoary, in coarſe powder, and ſaffron, of each half a pound, and of diſtilled water, three pints. Macerate for twenty-four hours, and then preſs out and ſtrain. Evaporate the ſtrained liquor to a pound and a half, and add of compound powder of crabs-claws, ſixteen ounces by weight; cinnamon and nutmeg, of each two ounces by weight; cloves, one ounce by weight; leſſer cardamom, half an ounce by weight; and double refined ſugar, two pounds.

Powder the ſpices together very finely, and adding the ſugar, make a confection. This is an improvement of the *confectio cardiaca* of the former diſpenſatory. The eſſential oil of the cardamom appeared, on an experiment made at the Hall, to be loſt in the evaporation of the tincture; and, therefore, the cardamom is now more properly added in powder.

Confectio *Damocratis*. See Mithridate.

Confectio *Fracaſtorii*. See Diascordium.

Confectio *Japonica*, was prepared of Japan earth, three ounces; tormentil root, nutmeg, and olibanum, of each two ounces; opium, diſſolved in Liſbon wine, a dram and a half; ſimple ſyrup and conſerve of roſes, of each fourteen ounces. An electuary of theſe ingredients ſupplied the place of *diaſcordium;* and the doſe was from a ſcruple to a dram.

Confectio *Opiata*, confection of opium, is prepared in the following manner: Take of hard purified opium, powdered, ſix drams by weight; long pepper, ginger, and caraway, of each two ounces by weight; ſyrup of white poppy, boiled to the conſiſtence of honey, three times the weight of the whole. Mix the purified opium with the heated ſyrup, and add the reſt in powder.

Confectio *Paulina*, a name given in the late London Diſpenſatory to the compoſition which uſed to be called *confectio archigenis*. It was ordered to be made in the following manner: Take coſtus or zedoary, cinnamon, long pepper, black pepper, ſtrained ſtorax, galbanum, opium, and Ruſſia caſtor, of each two ounces; of ſimple ſyrup, boiled to the conſiſtence of honey, an equal weight to thrice the ſpecies. Pemberton's London Pharm. p. 339.

CONFECTOR, among the *Ancient Romans*, a ſort of gladiator, hired to fight in the amphitheatre againſt beaſts; thence alſo denominated *beſtiarius*. See Gladiator.

The confectores were thus called *à conficiendis beſtiis*, from their diſpatching and killing beaſts.

The Greeks called them ϖαραϐολοι, q. d. *daring*, *raſh*, *deſperate;* whence the Latins borrowed the appellations *parabolani*, and *parabolarii*. The chriſtians were ſometimes condemned to this ſort of combat.

CONFECTS, or Confits, a denomination given to fruits, flowers, herbs, roots, and juices, when boiled and prepared with ſugar, or honey, to diſpoſe them to keep, or render them more agreeable to the taſte.

The ancients only confited with honey; at preſent, ſugar is more frequently uſed. Confects half-ſugared are thoſe only covered with a little ſugar, to leave more of the natural taſte of the fruit.

Confects are reduced to eight kinds; viz. *liquid confects*, *marmalades*, *jellies*, *paſtes*, *dry confects*, *conſerves*, *candies*, and *dragees*, or *ſugar-plums*.

Liquid confects are thoſe whoſe fruits, either whole, in pieces, in ſeeds, or in cluſters, are confited in a fluid tranſparent ſyrup, which takes its colour from that of the fruits boiled in it. There is a good deal of art in preparing theſe well; if they be too little ſugared, they turn; and if too much, they candy. The moſt eſteemed of the liquid confects are plums, eſpecially thoſe called mirabels, barberries, quinces, apricots, cherries, orange flowers, little green citrons from Madeira, green caſſia from the Levant, myrobalans, ginger, cloves, &c.

Marmalades are a kind of paſtes almoſt liquid, made of the pulp of fruits, or flowers, that have ſome conſiſtence; ſuch as apricots, apples, pears, plums, quinces, oranges and ginger. Marmalade of ginger is brought from the Indies by way of Holland: it is eſteemed good to revive the natural heat in old men. See MARMALADE.

Jellies are juices of ſeveral fruits, wherein ſugar has been diſſolved, and the whole, by boiling, reduced into a pretty thick conſiſtence; ſo as, upon cooling, to reſemble a kind of thin tranſparent glue, or ſize. Jellies are made of various kinds of fruits, eſpecially gooſeberries, currants, apples, and quinces: there are other jellies made of fleſh, fiſh, hartſhorn, &c. but they are not to be kept, being very ſubject to corrupt. See JELLY.

Paſtes are a kind of marmalades, thickened to that degree by a proper boiling, as to aſſume any form, when put into little moulds, and dried in the oven. The moſt in uſe are thoſe of gooſeberries, quinces, apples, pears, and orange flowers: thoſe of piſtachoes are the moſt eſteemed; thoſe of ginger are brought from the Indies.

Dry Confects are thoſe whoſe fruits, after having been boiled in the ſyrup, are taken out again, and drained, and put to dry in an oven. Theſe are made of ſo many kinds of fruits, that it would be hard to explain them all: the moſt conſiderable are citron and orange-peel, plums, pears, cherries, apricots, &c.

Conſerves are a kind of dry confects, made with ſugar, paſtes of flowers or fruits, &c. The moſt uſual among theſe, are thoſe of roſes, mallows, roſemary; of heps, of orange flowers, violets, jeſſamin, piſtachoes, citrons, and ſloes.

Note. The apothecaries, under the title of *conſerves*, comprehend all kinds of confects, both dry and liquid; whether of flowers, fruits, ſeeds, roots, barks, or leaves, prepared with ſugar or honey, to preſerve, &c. See CONSERVE.

Candies are ordinarily entire fruits, candied over with ſugar, after having been boiled in the ſyrup; which renders them like little rocks cryſtallized; of various figures and colours, according to the fruits encloſed within them. The beſt candies are brought from Italy. See CANDY.

Sugar-plums are a kind of little dry confects, made of ſmall fruits or ſeeds, little pieces of bark, or odoriferous and aromatic roots, &c. incruſted and covered over with a very hard ſugar, ordinarily very white. Of theſe there are various kinds, diſtinguiſhed by various names; ſome made of raſberries, others of barberries, melon-ſeeds, piſtachoes, filberds, almonds, cinnamon, orange-peel, corianders, aniſeeds, caraways, &c.

CONFEDERACIES OF POLAND. See POLAND.

CONFEDERACY, Fr. *Confederation*, an alliance, compact, or league between different princes and ſtates, for the ſupport of a common cauſe. See CONFEDERATION.

CONFEDERACY, in *Law*, is when two or more perſons combine to do any damage to another, or to commit any unlawful act.

Confederacy is puniſhable, though nothing be put in execution: but then it muſt have theſe four incidents; 1. That it be declared by ſome matter of proſecution; as by making of bonds or promiſes to one another: 2. That it be malicious; as for unjuſt revenge: 3. That it be falſe; *i. e.* againſt the innocent: and, laſtly, That it be out of court, voluntarily. See CONSPIRACY.

CONFEDERATE TROOPS, troops of different nations united together in one common cauſe againſt an enemy.

CONFEDERATION OF THE RHINE, in French *la Ligue du Rhin*, is the act by which ſeveral German ſtates, ſituated between the Rhine and the Mayne, ſeparated themſelves from the Germanic body, and aſſociated as confederated ſtates of the Rhine, under the protection of the French empire. The inſtrument of this confederation was ſigned at Paris, on the 12th of July 1806, and the ratifications were exchanged at Munich on the 25th of the ſame month. The contracting parties were the emperor of the French, on the one part, and on the other, the kings of Bavaria and Wi[illegible]berg, the archbiſhop of Ratiſbon as prince primate, the grand dukes of Baden, Berg, Heſſe Darmſtadt, Naſſau Weilbourg, and Naſſau Uſingen, the prince [illegible]lern-Hechingen, and Seigmaringen, Salm Salm, Salm Kyrburg, Iſenburg Birſtein and Lichtenſtein, the duke of A[illegible]remberg, and the prince of Leyn. They declar[illegible] would admit other German princes and ſtates i[illegible] where their union with the confederation might [illegible] conſiſtent with the general intereſt, and thus virtually annihilated the inconſiderable part that was left of the German empire. This induced Francis II. laſt emperor of Germany, and firſt of Auſtria, formally to abdicate the German empire, by his proclamation of the 6th of Auguſt 1806. It was then expected that a ſimilar confederation would be formed on the north of the Mayne under the protection of either Pruſſia or Ruſſia: but the king of Pruſſia having declared war againſt France, in October 1806, and having been completely overthrown at the battle of Jena, on the 14th of the ſame month, ſeveral other German ſtates haſtened to join the confederation of the Rhine, as Lippe Detmold, Schaumburg Buckeburg, Saxe Weimar, Saxe Gotha, Saxe Cobourg, and the newly created kingdom of Saxony. By the peace of Tilſit, which erects the Pruſſian provinces on the right bank of the Elbe, and the poſſeſſions of Heſſe Caſſel, Orange Fulda, and other petty German ſtates into a new kingdom, to be called the kingdom of Weſtphalia, the confederation of the Rhine is extended to the banks of the Elbe, and will probably receive conſiderable modifications from ſuch a large and important acceſſion of new members. Its original ſtipulations were that the confederated ſtates,

Art. I. are for ever ſeparated from the Germanic body, and united by a particular confederation, under the deſignation of the "Confederated States of the Rhine."

II. Renounce the laws; and

III. The titles of the empire.

IV. The elector arch-chancellor takes the title of prince primate and moſt eminent highneſs, which title ſhall convey no prerogative derogatory to the entire ſovereignty which every one of the contracting parties ſhall enjoy.

V. The elector of Baden, duke of Berg, and landgrave of Heſſe Darmſtadt, take the title of grand dukes; the chief of the houſe of Naſſau that of duke; and the count of Leyn that of prince.

VI. The affairs of the confederation ſhall be diſcuſſed in a congreſs at Frankfort on the Mayne; divided into two colleges, that of the kings and that of the princes.

VII. The members of the league muſt be independent of every foreign power. They cannot enter into any other ſervice but that of the ſtates of the confederation and its allies. Thoſe who have been in the ſervice of a foreign power, and chooſe to continue in the ſame, muſt abdicate their principality in favour of one of their children.

VIII. Should any prince be diſpoſed to alienate the whole or any part of his ſovereignty, he can only do it in favour of a confederate.

IX. All diſputes are ſettled in the aſſembly at Frankfort, where

X. The prince primate preſides. But if the two colleges deliberate ſeparately, he preſides in the college of kings, and the duke of Naſſau in the college of princes.

XI. The fundamental ſtatute is to be framed by the prince primate.

XII. The French emperor is protector of the confederation, and names the ſucceſſor of the prince primate.

XIII. to XXI. Enumerate the ceſſions made by members of the league: thus, Naſſau cedes to Berg the town of Denſs and its territory; Bavaria acquires the imperial city of Nuremberg and its territory: and

XXII. The prince primate receives Frankfort on the Mayne, and its territory, as his property.

XXIII. and XXIV. Enumerate the lordſhips over which the members of the confederation exerciſe the rights of ſovereignty.

XXV. They alſo enjoy the ſovereignty over the imperial knightdoms included within their boundaries.

XXVI. The rights of ſovereignty conſiſt in legiſlation, adminiſtration of juſtice, military conſcription or recruiting, and levying taxes.

XXVII. Regulates the patrimonial or private property of the ſubordinate princes and counts. Their domains cannot be ſold or given to any prince out of the confederation, without being firſt offered to the prince under whoſe ſovereignty they are ſituated.

XXVIII. Theſe ſubordinate princes and counts preſerve the privilege of being tried by their peers. Their fortune cannot be confiſcated, but their revenues may be ſequeſtrated during the life-time of the criminal.

XXIX. and XXX. Regulate the payment of debts.

XXXI. The ſubordinate princes or counts may take up their reſidence where they chooſe, and draw their rents or capitals without any reſerve.

XXXII. Public functionaries not retained by the new ſovereign, receive a penſion proportionate to the ſituation they held.

XXXIII. The ſame takes place with reſpect to religious orders loſing their income.

XXXIV. The confederates renounce all reciprocal claims, except the eventual right of ſucceſſion.

XXXV. Between the French emperor and the confederated ſtates there ſhall be federatively and individually an alliance, by virtue of which every continental war in which either is engaged ſhall be common to all.

XXXVI. In the event of any power making preparations for war, the contracting parties, in order to prevent ſurpriſe, ſhall, upon the requiſition of the miniſter of one of them at the aſſembly of the league, arm likewiſe. And as the contingent of the allies is ſubdivided into four parts, the aſſembly ſhall decide how many are to be called into activity. The armament, however, ſhall only take place upon the ſummons of the French emperor to each of the confederates.

XXXVII. The king of Bavaria binds himſelf to fortify Augſburgh and Lindau, and to form and maintain artillery and baking eſtabliſhments in the ſaid places.

XXXVIII. The contingent of each confederate is: France 200,000 men, Bavaria 30,000, Wirtemberg 12,000, Baden 8000, Berg 5000, Darmſtadt 4000, Naſſau, Hohenzollern; and others 4000.

XXXIX. Admits of the acceſſion of other German princes; and,

XL., as the concluding article, ſtipulates the exchange of the ratifications.

Of the two principal articles of the new conſtitution of the confederation of the Rhine, one relates to the eſtabliſhment of a ſuperior court of appeal, in which all cauſes between the ſovereigns and their ſubjects ſhall be finally decided. The other ſtipulates that the manufactures of each ſtate ſhall be allowed to be freely imported into all the other ſtates of the confederacy. Several new roads are to be made in order to facilitate commerce.

CONFERENCE, in its firſt and primary ſenſe, denotes mutual diſcourſe, and more eſpecially ſuch diſcourſe on ſerious and important ſubjects. It alſo denotes an appointed meeting for diſcuſſing ſome point, by perſonal debate; of this kind was that held at Ratiſbon, in 1601, at the joint deſire of Maximilian, duke of Bavaria, and Philip Lewis, elector Palatine, between ſome eminent Lutheran doctors on one ſide, and three celebrated Jeſuits on the other. The diſpute turned upon the two great points, to which almoſt all the conteſts between the Proteſtants and the Roman Catholics are reducible, *viz.* the rule of faith and the judge of controverſies. In 1615, another conference was held at Newberg between James Heilbronner, a learned Lutheran, and James Keller, a celebrated Jeſuit, by the appointment of Wolfgang William, prince Palatine, who had a little before that time embraced the Romiſh faith. But the moſt famous of all theſe conferences was that held in the year 1645 at Thorn, by the expreſs order of Uladiſlaus IV. king of Poland, between ſeveral eminent doctors of the Romiſh, Lutheran, and reformed churches. As this meeting was intended to heal the diviſions that prevailed among theſe churches, and to diſcover ſome method for healing their differences, and for effecting their reunion, it was on this account called the "Charitable conference." But the iſſue of this conference was very far from being favourable to the projected union. Some time after this, Erneſt, landgrave of Heſſe, in order to give a plauſible colour to his apoſtacy from the Proteſtant religion, and make it appear to be the reſult of examination and conviction, obliged Valerianus Magnus, a learned capuchin, to enter the liſts with Peter Habercorn, a reformed miniſter, in the caſtle of Rheinfield. Beſides theſe public conferences on the continent, there were others of a more private nature held, during the 17th century, between the doctors of the contending churches. The moſt remarkable of theſe was the famous diſpute between John Claude, the moſt learned of the Reformed divines in France, and Jaques Benigne de Boſſuet, whoſe genius and erudition placed him at the head of the Romiſh doctors in that country. This diſpute, held in the year 1683, terminated, like all the reſt, in widening the breach inſtead of healing it. Neither of the contending parties could be perſuaded to yield; but, on the contrary, they both returned from the field of controverſy more rivetted in their own opinions, and more averſe from thoſe of their adverſaries. Another conference was held at Leipſic, in 1631, between three Saxon doctors on the one ſide, and ſome of the moſt eminent divines of Heſſe-Caſſel and Brandenburgh on the other, with a view of repreſenting, with fidelity and preciſion, their reſpective doctrines, and for the purpoſe of diſcovering the obſtacles which prevented the union of the Lutheran and Reformed churches. The conference, however, though amicably conducted, broke up without having contributed in any reſpect to promote the ſalutary work of peace. The conference held at Caſſel in 1661, by the order of William VI., landgrave of Heſſe, between two profeſſors at Rintelen, on the ſide of the Lutherans, and two others of the univerſity of Marpurg on that of the Reformed, was attended with much greater ſucceſs than that of Thorn above mentioned: for, though it did not bring about a perfect uniformity of opinion, it produced an effect, which was in reality, much better, a ſpirit of Chriſtian charity and forbearance.

The moſt famous conferences of a ſimilar kind, held in England, were thoſe of *Hampton-Court* in 1604, and of the *Savoy* in 1661. The former was held by order of James I., on pretence of finding expedients, which might terminate the religious diſputes between the church and the puritans, and reconcile both parties. The profeſſed deſign of this conference was to examine the objections of the puritans againſt the doctrine, government, and diſcipline of the eſtabliſhed church, and to rectify its abuſes. But the progreſs and reſult of it evidently ſhew, that it was the deſign of the king to make an oſtentatious diſplay of his learning, and to mortify the puritans, who had favourable expectations from James's education in Scotland, and his profeſſed attachment to the church eſtabliſhed in that country, but who found, in the event, that he had conceived invincible prejudices againſt them. The diſputants on both ſides were nominated by the king. For the church, there were nine biſhops, and about as many dignitaries; and for the puritans, there were only four miniſters. This conference continued three days, *viz.* Jan. 14th, 16th, and 18th. The firſt day's conference was with the biſhops and deans; the puritan miniſters not being preſent; when the king made a ſpeech in commendation of the hierarchy of the church of England, congratulated himſelf, that he was now come into the "promiſed land," &c. &c.; and informed them, that the reaſon of his conſulting them by *themſelves* was to receive ſatisfaction from them: 1. About ſome things in the Common Prayer. 2. Concerning excommunication in the eccleſiaſtical courts. 3. About providing ſome well-qualified miniſters for Ireland; that if any thing ſhould be found meet to be redreſſed, it might be done without their being confronted by their opponents. After ſome alterations of no great importance, agreed on between the king and the biſhops, with regard to the confirmation of children, the abſolution of the church, private baptiſm, and baptiſm by women, and excommunication for leſſer crimes, his majeſty's ſcruples were ſatisfied; and thus ended the firſt day's conference. On the ſecond day, Jan. 16th, the four miniſters on the ſide of the puritans, together with Patrick Galloway, miniſter of Perth in Scotland, and two biſhops and ſix or eight deans on the other ſide, were convened. The king, ſeated in his chair, with his nobles and privy counſellors around him, informed the puritanical miniſters that he was ready to hear their objections againſt the eſtabliſhment. Upon which Dr. Raynolds, one of their number, in the name of his brethren, humbly requeſted: 1. That the doctrine of the church might be preſerved pure, according to God's word. 2. That good paſtors might be planted in all churches, to preach in the ſame. 3. That the book of Common Prayer might be fitted to more increaſe of piety. 4. That church government might be ſincerely miniſtered according to God's word. In the diſcuſſion of theſe points, Bancroft and the king took an active part. At the cloſe of this day's debate, his majeſty highly incenſed at the complaints ſtated by Dr. Raynolds, told the miniſters, that he found they were aiming at a Scots preſbytery; "which, ſays he, agrees with monarchy as well as God and the devil; there Jack and Tom and Will and Dick ſhall meet and cenſure me and my council. Therefore I reiterate my former ſpeech: "Le Roi s'aviſera." Stay, I pray, for one ſeven years before you demand; and then, if you find me grow purſie and fat, I may perchance hearken unto you. For that government will keep me in breath, and give me work enough. I remember how they uſed the poor lady, my mother, in Scotland, and me in my minority." Then turning to the biſhops, he put his hand to his hat and ſaid "my lords, I may thank you that theſe puritans plead for my ſupremacy; for if once you are out and they in place, I know what would become of my ſupremacy, for *no biſhop, no king*." When Dr. Raynolds ſaid he had nothing more to offer, the king ſaid, "if this be all your party have to ſay, I will make them conform, or I will hurry them out of this land, or elſe worſe." On the termination of this day's conference, ſome aſſerted that the puritans had been groſsly inſulted and ridiculed, and that they had not been allowed freedom of ſpeech; but the biſhops and courtiers flattered the king's wiſdom and learning, and called him the Solomon of the age. Bancroft fell upon his knees, and ſaid, "I proteſt my heart melteth for joy, that Almighty God of his ſingular mercy, has given us ſuch a king, as ſince Chriſt's time has not been." Chancellor Egerton ſaid, "he had never ſeen the king and prieſt ſo fully united in one perſon." The king was no leſs ſatisfied with his own conduct, and boaſted of his victory over the puritans. At the third day's conference, Jan. 18, the biſhops and deans were firſt called into the privy-chamber with the civilians, to ſatisfy the king about the high commiſſion and the oath ex officio; and when the king expreſſed his ſatisfaction with the latter, the old archbiſhop (Whitgift) was ſo tranſported as to exclaim, "undoubtedly your majeſty ſpeaks of the ſpecial aſſiſtance of God's ſpirit." A committee of biſhops and privy-counſellors was then appointed to conſider of leſſening the charges in the high commiſſion, for planting ſchools and proper miniſters in the kingdom of Ireland, and on the union of England and Scotland. After which Dr. Raynolds and his brethren were called in, not to diſpute, but only to hear the few alterations or explanations in the Common Prayer Book, that had been adopted; but when they expreſſed their wiſh that ſomething further might be done, or at leaſt that the ſurplice and croſs might not be urged, the king replied with a ſtern countenance, interrupting the biſhops who were about to anſwer, "We have taken pains here to conclude in a reſolution for uniformity, and you will undo all by preferring the credit of a few private men to the peace of the church; this is the Scots way; but I will have none of this arguing; therefore let them conform, and that quickly too, or they ſhall hear of it; the biſhops will give them ſome time, but if any are of an obſtinate and turbulent ſpirit, I will have them enforced to conformity." Thus ended this conference, and the opportunity for conciliation and union was loſt; and this was chiefly owing to the king's pedantry and love of adulation, to his high and arbitrary principles, and to his inveterate hatred of the Puritans.

The *Savoy* conference was held in purſuance of the declaration of Charles II. Oct. 25, 1660, concerning eccleſiaſtical affairs, when 12 biſhops and nine aſſiſtants were appointed on the part of the epiſcopal church of England, and as many miniſters on the ſide of the preſbyterians, to aſſemble at the biſhop of London's lodgings at the Savoy; "to review the book of Common Prayer, comparing it with the moſt ancient and pureſt liturgies; and to take into their ſerious and grave conſideration the ſeveral directions and rules, forms of prayer, and things in the ſaid book of Common-Prayer contained; and to adviſe and conſult upon the ſame, and the ſeveral objections and exceptions which ſhall be now raiſed againſt the ſame; and if occaſion be, to make ſuch reaſonable and neceſſary alterations, corrections, and amendments, as ſhall be agreed upon to be needful and expedient, for giving ſatiſfaction to tender conſciences, and the reſtoring and continuance of peace and unity in the churches under his majeſty's government and direction."

They were to continue four months from the 25th of March 1661, and then preſent the reſult of their conferences to his majeſty under their ſeveral hands. When the conference opened on the 15th of April, ſome difficulties occurred about the proper mode of proceeding; ſome of the preſbyterian party were for inſiſting only on a few matters of importance, judging that if theſe were gained, and an union followed, it might be more eaſy to obtain the others afterwards. But the majority, by the influence of Mr. Baxter, were for extending their deſires to the utmoſt, and thought themſelves bound by the words of the commiſſion, to offer every thing which they thought might conduce to the peace of the church; but when they were put in mind, that the king's commiſſion gave them no power to alter the government of the church, nor to inſiſt upon archbiſhop Uſher's model, nor ſo much as to claim the conceſſion of his majeſty's late declaration, they were much diſcouraged; for they were now convinced that all they were to expect were a few amendments in the liturgy and Common-Prayer Book. They wiſhed alſo to have conſulted their abſent brethren, and to have received from them a commiſſion in form; but this was denied. Inſtead of drawing up a few ſupplemental forms and making ſome amendments to the old liturgy, Mr. Baxter compoſed a new one, in the language of ſcripture, which he called “The Reformed Liturgy;” not with a deſign entirely to ſet aſide the old one, but to give men liberty to uſe either according to their own choice and approbation. This was preſented to the biſhops in the conference, together with exceptions to the “old liturgy.” This gave great offence, partly becauſe a liturgy, compoſed by a ſingle perſon in fourteen days, was ſet in competition with one which had been received in the church for a whole century; and partly, becauſe it was inconſiſtent with the commiſſion, and the biſhops' declaration of varying no further from the old ſtandard than ſhould appear to be neceſſary; and, therefore, the reformed liturgy was rejected at once without examination. When the preſbyterians preſented their exceptions to the liturgy, they accompanied them with “a petition for peace,” beſeeching the biſhops to yield to their amendments; to free them from the ſubſcriptions and oaths in his majeſty's late declaration, and not to inſiſt upon the re-ordination of thoſe who had been ordained without a dioceſan biſhop, nor upon the ſurplice, the croſs in baptiſm, and other indifferent ceremonies, enforcing their petition by various arguments and motives. Theſe exceptions were canvaſſed, and produced a variety of alternate objections and replies. The biſhops, however, would make no conceſſion to the prejudices of the preſbyterians; upon which they ſent them a large expoſtulatory letter, in which, after having repeated their objections, they lay the wounds of the church at their door. The term for the treaty being almoſt ſpun out in a paper controverſy, about 10 days before the commiſſion expired, a diſputation was agreed on, to argue the neceſſity of alterations in the preſent liturgy. Three of each party were choſen to manage the argument. The diſpute, however, terminated without effect. From arguments the preſbyterian miniſters deſcended to intreaties, and beſought the biſhops to compaſſionate ſcrupulous minds, and not to deſpiſe their weaker brethren; to all which the biſhops replied, that they were only commiſſioned to make ſuch alterations in the liturgy as ſhould be neceſſary, and ſuch as ſhould be agreed upon. Mr. Baxter ſays, that the biſhops would not abate the ſmalleſt ceremony, nor correct the groſſeſt error, for the peace of the church. Thus the king's commiſſion expired July 25, and the conferences ended without any proſpect of accommodation. It was agreed at the concluſion, that each party might repreſent to his majeſty, that they were all agreed upon the ends of the conference, which were the welfare, unity, and peace of the church, but ſtill diſagreed as to the means of procuring them. The biſhops thought they had no occaſion to repreſent their caſe in writing, but the preſbyterian commiſſioners met by themſelves, and drew up an account of their proceedings, with a petition for that relief which they could not obtain from the biſhops. Hume's Hiſt. vol. vi. 10. 13., vol. vii. 369.

CONFERVA, in *Botany*, a name occurring in Pliny for a water plant, ſuppoſed to be C. rivularis of Linnæus, ſo called, he ſays, *a conferruminando*, becauſe it cloſely adheres together, Linn. gen. 1207. Schreb. 1672. Juſſ. 6. Vent. 2, 32. Claſs and order, *cryptogamia algæ*. Nat. Ord. *Algæ*. Linn. Juſſ. Vent.

Gen. Char. Fibres ſimple, uniform, capillary, filamentous.” Linn. “Filaments capillary, ſimple or branched, jointed; joints numerous, often unequal.” Lam. Vent. “Seeds produced within the ſubſtance of the capillary or jointed frond, or in cloſed tubercles united with it.” Dr. Smith.

Species. I. *Simple.*

* *Immerſed.*

+ *In ſalt water.*

1. C. *confervicola*. Conferva upon conferva. Dillw conf. 8. Dill. Muſc. 552. tab. 85. fig. 21. “Filaments ſimple, minute, ſomewhat crowded, acute; partitions obſcure; joints cylindrical, unequal in length.” Dillw. *Filaments* rarely more than an eighth of an inch long, of a dark glaucous colour, tapering. Common in the lateſt months of autumn on various fuci and confervæ. 2. C. *flacca*. Dillw. 49. “Filaments ſimple, very ſlender, minute, flaccid; partitions tranſparent; joints very ſhort.” Growing in looſe patches of a green colour, about half or three-fourths of an inch long. *Joints* ſcarcely half ſo long as broad. Paraſitical on confervæ, and the ſmaller fuci in the neighbourhood of Swanſea. 3. C. *fucicola*. Velley Mar. Plant. Pl. 4. Dillw. 66. Wither. 4. 136. “Filaments cluſtered, ſimple, obtuſe; partitions tranſparent, ſlightly contracted; joints rather long.” Dillw. *Filaments* very numerous, thickly cluſtered at the root, diverging while in the water, from four to ſix lines long, of a dirty yellow or brown colour, ſomewhat gloſſy when dried. *Joints* about twice as long as broad, filled with minute granules. Paraſitical on fucus veſiculoſus, and ſometimes on nodoſus. 4. C. *curta*. Dillw. 76. “Filaments cluſtered, ſimple, ſomewhat cartilaginous or horny, erect, ſhort, attenuated at both ends; partitions tranſparent, ſlightly contracted; joints rather ſhort.” *Filaments* ſeldom more than three or four lines long, of an olive-brown colour, obtuſe, growing in roundiſh ſtiff tufts. *Joints* not much longer than thick. Paraſitical on fuci. 5. C. *carnea*. Dillw. 84. “Filaments ſimple, cluſtered, ſomewhat knotty, fleſh-coloured; joints rather ſhort, attenuated at both ends; juice collected into ſolitary globules.” *Filaments* from a quarter to half an inch long, rather obtuſe. *Partitions* dark-coloured. *Joints* ſometimes about twice the length of the diameter, ſometimes little more than the length; colourleſs, except where the juice is collected. Paraſitical in looſe tufts on other confervæ. 6. C. *capillaris*. Linn. Sp. Pl. 14. Lam. 14. Dill. p. 25 tab. 5. fig. 25. A. Dillw. 9. (C. linum; Flor. Dan. 771. C. paluſtris, ſive filum marinum Anglicum. Rai. Syn. p. 60. n. 16.) “Filaments ſimple, cylindrical, rather rigid, curled, entangled, brittle; partitions tranſparent; joints cylindrical, ſhort; capſules ſeſſile.” *Filaments* three or four feet long, about the thickneſs of large thread, pale yellowiſh green, entangled, but never adhering together; perfectly flaccid after it has been expoſed a few minutes to

the air. *Partitions* quite tranſparent, with a thin blackiſh line on each ſide. *Joints*, when dry, generally appearing alternately compreſſed. Found in the ditches and ſtagnant pools of ſalt marſhes. 7. C. *tortuoſa.* Dillw. 46. "Filaments ſimple, rather rigid, entangled, ſlender; partitions tranſparent; joints cylindrical, rather long." Reſembling the preceding ſpecies in miniature. *Filaments* as fine as human hair, leſs brittle than thoſe of C. capillaris; joints nearly twice as long as broad. Found in ſalt-pools, and on rocks in the ſea. 8. C. *ærea.* Dillw. 80. "Filaments ſimple, rather rigid, nearly ſtraight; partitions glaſſy-tranſparent, contracted; joints oblong, ſhort." *Filaments* ſeveral from the ſame root, from ſix to fifteen inches long, ſometimes nearly the thickneſs of a crow quill, generally about that of large thread, dark or blueiſh green, brittle. *Joints* not ſo long as broad, rounded at each end. On ſtones in the ſea.

†† *In freſh water.*

9. C. *ſordida.* Dillw. 60. "Filaments ſimple, ſlender; partitions ring-like; joints rather long, tranſparent." *Filaments* very long, extremely ſlender, entangled. *Joints* about four times as long as thick. In ponds, pools, and ditches frequent. In ponds forming a ſemi-tranſparent cloud-like maſs round the graſs or reed on which it grows, of a yellowiſh-green colour. In ſmall currents, floating, in denſer maſſes, on the ſurface. 10. C. *inflata.* Smith Eng. Bot. 1670. Conjugata inflata; Vaucher conf. 68. tab. 5. fig. 8. "Filaments ſimple; joints three times as long as broad; when fertile, ſwelling and elliptical." *Filaments* but the 700th part of an inch in diameter, tranſparent, almoſt colourleſs. *Joints* at firſt exactly cylindrical, marked with green colouring matter in ſpiral lines; afterwards ſwelling, elliptical, each protruding a lateral tube, ſo as to unite with ſimilar tubes of a neighbouring plant. The colouring matter of one joint paſſes into the other, its ſpiral appearance being entirely loſt. At length each joint which has received it ſwells ſtill more, growing quite elliptical, and filled with a ſolid green body, which M. Vaucher has proved to be a ſingle ſeed, producing in due time a ſolitary young plant. Theſe appearances cannot be perceived without the aid of a microſcope. Found by Mr. W. Boner at Henfield in Suſſex. 11. C. *punctalis.* Dillw. 51. "Filaments ſimple, ſlippery, very ſlender; partitions obſcure; joints rather ſhort, cylindrical; juice finally collected into ſolitary globules." *Filaments* from one to two inches long, ſo ſlender, as, when ſingle, ſcarcely to be diſtinguiſhed by the naked eye. In ditches and pools not unfrequent. 12. C. *bipunctata.* Dillw. 2. Smith Eng. Bot. 1610. Roth Cat. Bot. ii. p. 204. (C. ſtellina; Muller in Nov. Act. Pet. iii.) "Filaments ſlippery, yellowiſh, joints ſhort, cylindrical, with two ſpots." *Joints* remarkable in having each two dark ſpots, frequently furniſhed with a green longitudinal ſtreak running through them; theſe ſpots ſometimes fill nearly the whole, ſometimes only a ſmall portion of the joint, and, when verging upon decay, aſſume a ſtellated appearance; but are not viſible without the aid of a microſcope. 13. C. *nitida.* Dillw. 4. Flor. Dan. tab. 819. (C. rivularis; Hudſ. Flor. Ang. 1. *β.* C. ſericea craſſior & varie extenſa. Dill. p. 13. tab. 2. fig. 2. C. decimina; Mull. nov. act. Pet. iii. C. ſetiformis; Roth. Cat. Bot. Faſc. 1. p. 171. 2. p. 103. Byſſus paluſtris confervoides, Mich. Gen. tab. 89. fig. 6.) "Filaments ſimple, ſhining, ſlippery; joints rather long, cylindrical; granules of the fructification doubly ſpiral." *Filaments* a foot or more long, about the thickneſs of a human hair, dark green, growing at the bottom of the water in looſe irregular patches, not ſufficiently matted as to contain air bubbles, nor ſo much entangled as in many others. 14. C. *ſpiralis.* Dillw. 3. Smith Eng. Bot. 1656. Roth Cat. Bot. ii. p. 202. (C. quinina; Mull. act. nov. Pet. iii.) "Filaments ſimple, ſlippery; joints cylindrical, rather long; granules of the fructification, ſimply ſpiral." *Filaments* longer and more ſlender than thoſe of nitida, anaſtomiſing like thoſe of C. inflata. 15. C. *jugalis.* Dillw. 5. Flor. Dan. tab. 883. (C. ſcalaris; Roth. Cat. Bot. ii. p. 196.) "Filaments ſimple, flaccid, often conjugate by pairs; granules of the fructification doubly ſpiral; finally collected into globules." In pools and ditches. Mr. Dillwyn ſtrongly ſuſpects, that C. nitida (n. 13.), is only the preſent plant in an earlier period of its growth. 16. C. *genuflexa.* Dillw. 6. Roth. Cat. Bot. ii. p. 199. (C. ſerpentina; Mull. nov. act. Pet. iii.) "Filaments ſimple, very ſlender, brittle, here and there knee-bent and conjugate; joints rather long, cylindrical; granules collected into lines." Filaments as far as can be judged, conſidering their brittleneſs, not more than one or two inches long, anaſtomiſing occaſionally at very uncertain diſtances, and only where they are geniculate, not regularly paired as in C. jugalis, but connecting themſelves with any other that is near them, and manifeſting a ſtrong affinity to the next ſpecies. In pools and ditches. 17. C. *reticulata.* Linn. Sp. Pl. 11. Lam. 11. Smith Eng. Bot. 1687. Dill. p. 20. tab. 4. fig. 14. (Hydrodictyum; Vaucher Conf. 88. tab 9.) "Filaments united into the form of a tubular net." *Filaments* green, tubular, forming a very delicate net, open at both ends; meſhes generally with five ſides, ſometimes with four or ſix. M. Vaucher found the old plants in a ſtationary condition during winter; but in ſpring the joints ſwelled, and gave out ſimple cylindrical maſſes of green matter. Each maſs ſoon became a reticulated tube, which in two or three months grew to the full ſize of the parent plant. It grows looſely, floating in ſtill water: but not very common. 18. C. *rivularis.* Linn. Sp. Pl. 1. Lam. 1. Dillw. 39. Smith Eng. Bot. 1654. (C. compacta; Roth. Cat. Bot. i. p. 170. C. fluviatilis ſericea, vulgaris & fluitans; Dill. p. 12. tab. 2. fig. 1. C. Plinii Rai. Syn. p. 58.) "Filaments ſimple, dark green, ſlender, very long, very denſely compact, frequently twiſted; joints rather ſhort." Filaments often two or three feet long. 19. C. *lucens.* Dillw. 47. Smith Eng. Bot. 1655. "Filaments ſimple, ſlender, glaucous, ſlippery; joints ſhortiſh; granules collected in faſciæ." Filaments ſeldom more than three inches long, tapering. On rocks and ſtones in clear rapid rivulets. 20 C. *diſſiliens.* Dillw. 63. "Filaments ſimple, ſtraight, brittle; partitions but little contracted, often looſe; joints ſhort, with a dark ſpot in the middle." Filaments from three to ſix inches long, leſs than a human hair in diameter, dark green, often breaking at the partitions and remaining connected at one extremity; joints about half as long as thick. In ditches on reeds and other aquatic vegetables. 21. C. *pectinalis.* Dillw. 24. Smith, Eng. Bot. 1611. Mull. nov. act. Pet. iii. (C. bronchialis; Roth. Cat. Bot. i. p. 186.) "Filaments ſimple, tranſparent, broken, acuminate; partitions often looſe; joints very ſhort, cryſtalline-tranſparent in the middle." *Filaments* ſeldom half an inch long, dirty green, to the naked eye reſembling decayed vegetable matter, when entire gradually tapering to a point, and bearing ſome reſemblance to the antennæ of a lobſter, frequently breaking at the partitions, and remaining connected at one extremity. *Joints* appearing coloured at each end by a green fluid, which, as the plant approaches to decay, collapſes, ſometimes forming into ſmall globular maſſes, and ſometimes diſappearing entirely. In rivers and ſtagnant waters, adhering to decaying wood and vegetables. 22. C. *flocculoſa.* Dillw. 28. Roth. Cat. Bot. p. 192. tab. 4. fig. 4. and tab. 5. fig. 6. "Filaments moſt commonly ſimple, minute; partitions looſe; joints priſmatic, alternately refracted." *Filaments* ſeldom more than a quarter of an inch long,

varying from a pale to a greeniſh brown. *Joints* with a double line running through the middle, and frequently with ſome tranſverſal bands; as they adhere to each other only in a ſingle point, and always at alternate ends, they give the plant the appearance of a ſtring of parallelograms, united at the corners. It might be taken for a much broken piece of C. pectinalis, but the joints cannot be ſo diſpoſed as to form one regular line. In pools and ſlow ſtreams, adhering to decaying vegetables and to other confervæ. eſpecially to C. glomerata. 23. C. *fontinalis*. Linn. Sp. Pl. 2. Lam. 2. Flor. Dan. tab. 651. fig. 2. Dillw. 64. (C. minima byſſi facie; Dill. p. 14. tab. 12. fig. 3.) “Filaments ſimple, cylindrical, truncate, dark green, faſciated; partitions obſcure; joints very ſhorts.” *Filaments* without any apparent root, equally obtuſe at both ends. Common in rivers, pools, and ditches, generally floating in irregular maſſes on the ſurface. 24. C. *limoſa*. Dillw. 20. (C. gelatinoſa, omnium tenerrima et minima aquarum limo innaſcens; Dill. p. 15.) “Filaments ſimple, very ſlender, ſhort, mucous, denſely compact, blueiſh green, ſlippery; partitions indiſtinct.” Common on the muddy edges of rivers, ditches, and ponds, repreſenting to the naked eye, except at the margin, where it is fibrous, a widely expanded, thin, ſhapeleſs gelatinous maſs, ſometimes floating at the top of the water. In either caſe the only mode to examine it, is to carry it home, without allowing it to dry, and to put it in a pan of water, where, in the ſpace of a night, it will ſhoot out an immenſe number of threads, viſible to the naked eye only from their number; theſe viewed through a microſcope appear obtuſe at each end, and croſſing each other without any regular order. Mr. Dillwyn is inclined to think that this is only the laſt ſpecies in a younger ſtate; the principal difference is in the ſize and colour; in C. fontinalis the filaments are much larger, browner, and not gloſſy; the joints alſo are far more diſtinct, and more regularly diſpoſed. 25. C. *violacea*. Hudſ. Flor. Ang. p. 592. (C. confragoſa; Lightf. Flor. Scot. p. 976. Dill. p. 15. tab. 2. fig. 4.) “Filaments ſimple, equal, violet.” *Filaments* about half an inch long, of a beautiful violet or indigo colour, of a ſlippery mucous ſubſtance, ſo extremely fine as to be undiſtinguiſhable by the naked eye, and ſo crowded together as to form, when moiſt, a gelatinous maſs, and when dry, a membranous lamina. Found by Lightfoot on the rocks in the waterfalls of the mountain of Goatfield in the Iſle of Arran, and ſaid by Dillenius to grow in Alpine rivulets near Llanberis. 26. C. *echinulata*. Smith Eng. Bot. 1378. “Glaucous, ſtems ſimple, ſpreading every way from a centre, and forming a globe.” Sent by the Rev. Mr. Davies from a lake in Angleſea. It covers the ſurface of the water in the months of June and July, and conſiſts of innumerable minute globules of a glaucous or verdigreaſe green, all nearly of a ſize. When examined with a microſcope each globule appears to be compoſed of a number of ſimple cylindrical ſhort filaments apparently ſpringing from a ſolid centre. Under a very high magnifier theſe filaments are found to be formed of ſhort uniform joints, each of which is of an equal thickneſs throughout, but the upper ones gradually diminiſh in ſize. Mr. Dawſon Turner ſuggeſts that this minute vegetable ought probably to be referred to Roth's new genus rivularia, to which ulva incraſſa and U. pruniformis of Engliſh botany belong. Thoſe ſpecies are of a pulpy ſubſtance, cloathed with jointed filaments.

** *Not immerſed.*

27. C. *ericetorum*. Dillw. 1. Smith Eng. Bot. 1553. Roth Cat. Bot. ii. p. 206. “Filaments ſimple, ſlender, proſtrate, denſely entangled; partitions ſcarcely contracted; joints about as long as they are broad.” *Filaments* from half an inch to an inch long, of a dull purple colour, covering the moiſt ſandy earth in large patches. Common on moiſt heaths. 28. C. *muralis*. Dillw. 6. Smith Eng. Bot. 1554. “Filaments ſimple, very ſlender, proſtrate, denſely entangled, ſomewhat rigid; joints very ſhort, ſlightly ſwelled; partitions obſolete.” *Filaments* about an inch long, ſcarcely diſcernible by the naked eye, covering the ſubſtances on which they grow with a fine cloſe green mat. Common upon damp walls, ſtones, and neglected ſhady walks. 29. C. *decorticans*. Dillw. 26. “Filaments ſimple, cloſely interwoven, glaucous; partitions obſcure; joints ſhort.” *Filaments* growing in large patches ſo intimately interwoven as to peel off in flakes, bearing a conſiderable reſemblance to a piece of ſilk or ribbon. It differs from C. muralis in its much greater tenacity and darker colour. Not unfrequent on damp walls and ſtones.

† *In ſalt-water.*

30. C. *polymorpha*. Linn. Sp. Pl. 17. Dillw. 44. (C. marina geniculata nigra palmata; Dill. p. 32. tab. 6. fig. 35. Ceramium faſtigiatum. Roth Cat. Bot. ii. p. 175.) “Filaments dichotomous, faſtigiate, ſomewhat cartilaginous; joints ſhort; capſules on the upper branchlets, egg-ſhaped, ſeſſile.” *Filaments* about the thickneſs of horſe hair, repeatedly dichotomous, with rather acute angles, of a dark purple colour when young, afterwards becoming black. Common on the larger fuci, moſt commonly on F. nodoſus, in thick tufts, two or three inches long. 31. C. *lanuginoſa*. Dillw. 45. “Filaments nearly ſimple, very minute; of a ruſty colour; joints rather long, pellucid in the middle; capſules ſeſſile, unilateral.” In the ſea, adhering to other confervæ. 32. C. *nigra*. Hudſ. Flor. Ang. p. 595. “Filaments equal, branched, very long; branches alternate, many-cleft, very ſhort.” *Filaments* five inches long, black, ſtiffiſh; branches faſciculated. On the Yorkſhire coaſt. 33. C. *byſſoides*. Dillw. 58. Eng. Bot. 547. “Filaments more than twice pinnated; branches and branchlets alternate; uppermoſt ones extremely ſhort, ſomewhat faſciculate; partitions from the union of the veins; joints rather long; capſules egg-ſhaped, ſeſſile.” *Filaments* extremely flaccid, zig-zag, tranſparent, beautifully ſtriated by longitudinal veins, each of which arch over at or near the ſame place, and appear to form the partition. Common on moſt of our ſhores, from three to five inches long, varying in colour from a reddiſh brown to a light or purpliſh red. 34. C. *paraſitica*. Hudſ. Flor. Ang. p. 604. Eng. Bot. 1429. “Filaments branched; branches doubly and alternately pinnated; capſules axillary, ſolitary, oblong.” *Filaments* an inch long or more, purpliſh, brown, ſlender, cylindrical, with the ſame jointed and tubular ſtructure as the preceding. Paraſitic on fuci, found rarely on the coaſt of Yorkſhire, Devonſhire, and Cornwal. Dr. Smith obſerves that the laſt two ſpecies have the jointed ſtructure of conferva, but agree better with the character of fuci in their fructification. The ſame obſervation will apply to ſeveral of the following ſpecies. 35. C. *nigreſcens*. Hudſ. Fl. Ang. p. 602. Smith Eng. Bot. 1717. “Filaments much branched; branches alternate, elongated; ultimate ones ſhort, crowded, awl-ſhaped; joints rather broader than long, compound.” *Filaments* from four to ſix inches long, blackiſh. *Joints* a little contracted, conſiſting of a circular double ſeries of numerous parallel tubes, ſimilar to thoſe of C. byſſoides. Mr. Stackhouſe is ſaid to have found the fructification in ſmall lateral nodules on the coaſt of Scotland, Devonſhire, and Cornwal. 36. C. *fuſca*. Hudſ. 602.

"Filaments much branched; branches and branchlets alternate, ſimple." *Filaments* three or four inches long, dark brown or reddiſh; branches long; branchlets ſhort, diſtant. *Fructifications* terminal and lateral, ſeſſile, ſmall, roundiſh, cluſtered. 37. C. *mertenſii.* Smith Eng. Bot. 999. "Filaments much branched; branches oppoſite, pinnated; joints ſhort; capſules minute, acorn-ſhaped, on ſhort peduncles." In habit reſembling fucus wigii. *Filaments* about three inches long, pale yellow, pinnated from their very origin; pellucid; branches ſhort, diſtichous, horizontal, generally ſimple. *Partitions* darker, and thence viſible. *Capſules* viſible only with a good glaſs. Found on the beach near Yarmouth. Mr. Dawſon Turner. 38. C. *fucoides.* Hudſ. Fl. Ang. p. 603.—Dillw. 75. Eng. Bot. 1743. "Filaments capillary, ſomewhat cartilaginous, much branched; partitions from the union of the nerves; joints compound, ſhortiſh, ſtriated; capſules ſolitary, egg-ſhaped, ſeſſile." *Filaments* from two or three inches to a foot long, reddiſh-brown, becoming darker and almoſt black with age, remarkably thick and buſhy in its growth, ultimate branches awl-ſhaped, all alternate. *Joints* of the ſtem and principal branches three times as long as broad; of the branchlets about as long as broad, each conſiſting of a ſimple circular ſeries of numerous parallel tubes. *Capſules* terminal and lateral, ſmall, obtuſe, diſcharging their ſeeds at the ſummit. On rocks and ſtones in the ſea, frequent. 39. C. *atrorubeſcens.* Dillw. 70. "Filaments branched, ſtriated; branches elongated, generally alternate, branchlets ſhort. awl-ſhaped, faſciculated; capſules egg-ſhaped, peduncled." *Filaments* from four to nine inches long, the thickneſs of ſmall thread, growing ſeparately, varying from a light purple to a duſky red, and becoming black with age or by drying, ſtriated under the microſcope by longitudinal ſpiral veins, which arch over at or near the partitions, and at firſt ſight appear to form them. *Joints* in the principal branches often more than twice as long as broad, in the branchlets about equal in length and breadth. *Capſules* either lateral or terminal. In the ſea, adhering to rocks, ſtones, and ſhells. 40. C. *roſea.* Smith Eng. Bot. 966. Dillw. 17. (Ceramium roſeum. Roth Cat. Bot. ii. p. 182.) "Filaments repeatedly branched; branches and branchlets alternate, approximate; partitions tranſparent, a little contracted; joints oblong; capſules unilateral, ſeſſile, ſomewhat globular." *Filaments* from an inch and a half to three inches long, in their thickeſt parts nearly as fine as human hair, ſo fine near their tips as to be ſcarcely viſible, very flaccid, when floating in water reſembling beautiful feathers, roſe-coloured. In the ſea, on rocks, fuci, and other ſubſtances. 41. C. *coccinea.* Hudſ. Flor. Ang. p. 603. Eng. Bot. 1055. Dillw. 36. (C. plumoſa. Lightf. 996. Ellis Philoſ. Tranſ. vol. lvii. 425. tab. 18. fig. c. c. d. D. Ceramium hirſutum. Roth Cat. Bot. ii. 169. tab. 4.) "Filaments ſomewhat cartilaginous, much branched; main ſtem rough with hairs; branches alternate, more than twice alternately pinnated; extreme branchlets faſciculated, pencil-ſhaped; partitions obſcure; joints ſhort; capſules egg-ſhaped." *Main ſtem* nearly as thick as common twine, ſolitary, moſtly of a darker red than the branches. *Partitions* ſcarcely perceptible in the main ſtem and larger branches, but very apparent in the ſmaller ones, dividing them into ſhort tranſparent joints. *Capſules* bright red early in ſpring, becoming gradually darker, and in May diſcharging the ſeeds by an aperture at the tip. On rocks and ſtones in the ſea common. 42. C. *turneri.* Smith Eng. Bot. 1637. "Repeatedly branched, very ſlender, tufted; ultimate branches all pectinated on the upper ſide; joints tranſparent, cylindrical; capſules globular, ſeſſile between the teeth of the branches, unilateral." Pectinated *branchlets* oppoſite. *Capſules* deep red, ſcattering the ſeeds over the branches. *Seeds* large. In the ſea, off the Iſle of Wight. 43. C. *plumula.* Ellis Phil. Tranſ. vol. lvii. p. 426. Dillw. 50. "Filaments much branched; branches alternate, pinnated; pinnæ oppoſite; ultimate branchlets unilateral; joints longiſh; capſules ſhort, pedicelled." Whole plant deep red, pellucid. *Partitions* dark. *Capſules* very numerous, unilateral on the ultimate branchlets, diſcharging the ſeeds at the tip. In the ſea, adhering to confervæ. 44. C. *tetrica.* Dillw. 81. "Filaments repeatedly pinnated; pinnæ and pinnulæ alternate; ultimate ones curved; joints rather long; capſules generally only one on each ultimate branchlet, globular, peduncled." *Stems* ſeveral from the ſame callus, forming thick entangled tufts of a browniſh-red colour, ſix or eight inches long, about the thickneſs of horſe hairs. On rocks and fuci in the ſea. 45. C. *diaphana.* Lightf. Flor. Scot. 996. Hudſ. Flor. Ang. 653. Dillw. 38. Smith Eng. Bot. 1742. (C. noduloſa. Hudſ. Flor. Ang. 600. C. marina nodoſa lubrica, ramoſiſſima et eleganter rubens. Dill. 35. tab. 7. 40.) β C. purpuraſcens. Hudſ. "Filaments capillary, repeatedly forked, divaricated; ultimate diviſions like a pair of forceps; partitions obſolete; joints ſhort, pellucid in the middle, deep red at each end; capſules lateral, ſolitary, globular." From two to ſix inches high, preſenting to the naked eye the appearance of a ſeries of ſmall beads, alternately coloured and pellucid. Common in the ſea, on rocks, ſtones, and fuci. 46. C. *rubra.* Hudſ. Flor. Ang. 600. Smith Eng. Bot. 1166. Dillw. 34. (C. noduloſa. Lightf. Flor. Scot. 944. C. geniculata, ramoſiſſima lubrica longis ſparſiſve ramulis. Dill. 35. tab. 6. fig. 38. A. Ceramium virgatum. Roth Cat. Bot. i. 148. tab. 8. fig. 1.) "Filaments repeatedly branched, thread ſhaped, thickly jointed; ultimate branches briſtle-ſhaped, forked; capſules ſomewhat globular, ſeſſile, ſolitary, lateral." Eighteen or twenty inches high, light red or purple, very liable to bleach. *Filaments* one or more from the ſame callus, about the ſize of ſewing-ſilk; partitions dark red, more or leſs contracted; joints beautifully reticulated, pellucid towards the centre. Common on rocks and ſtones in the ſea. 47. C. *tetragona:* With. Bot. Arr. 34. 405. Dillw. 65. Eng. Bot. 1690. "Filaments much branched; branchlets faſciculated, ſhort, generally ſimple; joints ovate-cylindrical; capſules ſeſſile, ſomewhat globular." Seldom more than two inches long. *Stems* ſeveral from one callus, ſtraight, branched on all ſides, forming an irregular ovate general outline, of a light purpliſh-red colour; branches ſquare. Paraſitical on fungi. 48. C. *elongata.* Hudſ. Flor. Ang. 599. Dillw. 33. (Fucus diffuſus. Hudſ. Flor. Ang. 589.) "Filaments much branched, cartilaginous; branches and branchlets elongated, diffuſe, briſtle-ſhaped veined; partitions obſcure; joints very ſhort; capſules egg-ſhaped, ſeſſile." Exceeding in ſize every other Britiſh conferva. Main *ſtem* as thick as common twine, purpliſh-red; branchlets paler; partitions dark-coloured. *Capſules* ſcattered ſparingly on the ultimate branches. On rocks, oyſter-ſhells, &c. 49. C. *littoralis.* Linn. Sp. Pl. 6. Lam. 6. Dillw. 31. (C. marina capillacea longa, ramoſiſſima, mollis, Dill. 23. tab. 4. fig. 19.) "Filaments much branched, very ſlender, zig-zag, thickly matted; branches and branchlets acuminate; partitions obſcure; joints cylindrical, ſhort." *Filaments* from ſix to nine inches long, of a dull olive-green colour; branches generally alternate, making an acute angle with the ſtem. *Capſules* globular, ſcattered irregularly on the branches, rarely found. On rocks and fuci, common. 50. C. *comoides.* Dillw. 27. Smith Eng. Bot. 1700. "Filaments capillary, zig-zag, branched; branches ſcattered, ſharp-pointed, but little ſpreading; partitions ſcarcely viſible." Nearly allied to the preceding. *Filaments* ſeldom more than an inch long, purple-brown, lying one over another, on the round pebbles in the ſea, ſo as to have a ſtriking reſemblance to an infant's head. 51. C. *tomentoſa.* Hudſ. Flor. Ang. 594. Dillw. 56. (C. marina tomentoſa, minus tenera et ferruginea. Dill. 19. tab. 3. fig. 13.) " Filaments much branched, very ſlender, thickly matted, divaricated, extreme branchlets ſimple; joints long." *Filaments* from three to five inches long, of a pale greeniſh or ruſſet-brown colour; branches ſo ſlender as to be ſcarcely viſible without a microſcope, iſſuing at right angles. *Joints* at leaſt three times as long as thick. *Partitions* dark brown. Frequent, generally paraſitical on fucus veſiculoſus. 52. C. *albida.* Hudſ. Flor. Ang. 595. (C. marina tomentoſa, tenerior et albicans. Dill. 19. tab. 3. fig. 12. C. tomentoſa β. Roth.) " Filaments much branched, very ſlender, equal; branches ſimple, faſciculated, white." *Filaments* ſcarcely ſeparately viſible to the naked eye, pale green, ſoft, reſembling cotton. Found in ſalt water, ditches, and pools in the iſland of Selſey in Suſſex. 53. C. *ſetacea.* Hudſ. Flor. Ang. 599. Smith Eng. Bot. 1689. Dillw. 82. (C. marina gelatinoſa, corallinæ inſtar geniculata, tenuior. Dill. 33. tab. 6. fig. 37.) " Filaments alternately and repeatedly branched, taper-pointed, faſciculated, ſlippery; joints a little ſwelling, at leaſt four times as long as broad; lateral ſhoots bearing tufts of filaments containing many globular ſeeds. Seldom exceeding four or five inches in length, of a rich crimſon colour. On rocks and ſtones in the ſea, not unfrequent at the latter end of ſummer and beginning of autumn. 54. C. *borreri.* Smith Eng. Bot. 1741. " Filaments capillary, repeatedly branched; branches alternate, ſpreading in two directions, zig-zag; ultimate ones faſtigiate; joints cylindrical, about twice as long as broad." *Filaments* in tufts, about two inches long, of a delicate pink colour, turning orange when dry. *Fructification* unknown, but conjectured by Dr. Smith to reſemble that of C. ſetacea. Gathered on Yarmouth beach by W. Borrer, eſq. F. R. S. 55. C. *ſtricta.* Dillw. 40. " Filaments ſomewhat dichotomous, faſciculated, veined; joints long." *Filaments* in thick bundles, many from the ſame root, ſeldom more than three inches long, of a dull crimſon colour, repeatedly divided. *Joints* about three times as long as broad. On rocks in the ſea, at Dover and Swanſea. 56. C. *rothii.* Turton's Syſt. Nat. 6. 1806. Dillw. 73. Eng. Bot. 1702. (C. violacea. Roth. Cat. Bot. i. 190. tab. 4. fig. 1.) " Filaments erect, dichotomous, ſhort, denſely tufted, crimſon; branches alternate; joints very ſhort." *Filaments* very ſlender, from three to twelve lines long. *Joints* cylindrical, about twice as long as broad. On rocks by the ſea-ſhore. 57. C. *corallinoides.* Linn. Sp. Pl. 15. (C. marina gelatinoſa corallinæ inſtar geniculata craſſior. Dill. 33. tab. 6. fig. 36.) " Filaments dichotomous; joints thicker at the top." *Filaments* bright red or white, ſlippery, very tender, almoſt diſappearing when dry. On ſtones on the ſea-ſhore. 58. C. *tubuloſa.* Hudſ. Flor. Ang. 600. (C. marina fiſtuloſa. Dill. 34. tab. 6. fig. 39. Ulva confervoides. Linn.) " Filaments much branched; joints oval, alternately compreſſed." *Filaments* from two to four inches long, yellowiſh green; branches knotted, hollow. On rocks, ſtones, and fuci. 59. C. *catenata.* Linn. Sp. Pl. 16. Lam. 16. (C. ramoſa, geniculis longioribus cateniformibus. Dill. 27. tab. 5. fig. 27.) " Filaments branched, green; joints oblong, forming a kind of chain, with links alternately broader and narrower." On the coaſts of Carolina, the Bahama iſlands, and the ſouth of Europe. 60. C. *ſcoparia.* Linn. Sp. Pl. 9. Lam. 9. Smith Eng. Bot. 1552. Dillw. 52. (C. marina pennata. Dill. 24. tab. 4. fig. 23.) " Filaments much branched, rigid; branches faſciculated, ultimate diviſions alternate, acuminate; partitions obſcure; joints ſhort." Whole plant of a browniſh olive, changing when dry to a ruſſet-brown colour. *Filaments* from two to ſix or nine inches long; upper branches longer and more cluſtered than the lower, giving the plant a bruſh-like appearance. *Joints* about as long as thick. Frequent on the ſea coaſt on ſtones and pebbles. 61. C. *pennata.* Hudſ. Flor. Ang. 604.—Dillw. 86. " Filaments branched; upper branches pinnated; pinnulæ nearly oppoſite, nearly horizontal, approximate, ſtiff and ſtraight; partitions obſcure; joints ſhort; tubercles ſeſſile, ſpherical." Often confounded by botaniſts with the preceding. *Filaments* in buſhy tufts from half an inch to two inches long, olive green, brown when dry. On rocks, fuci, & corallines. 62. C. *verrucoſa.* Smith Eng. Bot. 1688. " Branches irregularly ſcattered and ſubdivided, ſcarcely jointed, ſtudded with rough warts." *Filaments* three or four inches long, pale reddiſh brown, capillary, but uneven, ſomewhat twiſted, not perceptibly jointed, except in the youngeſt ſhoots, where an interruption of colour is ſometimes perceived at intervals. Found on the coaſt of Hampſhire and Cornwal. 63. C. *villoſa.* Hudſ. Flor. Ang. 603.—Smith Flor. Ang. 546.—Dillw. 37. " Filaments branched; branches and branchlets oppoſite, diſtant; joints very ſhort: partitions obſcure, villous." *Stem* from ſix inches to three feet high, greeniſh yellow, ſeldom more than thrice divided; hairs in whorls on about every fourth or fifth joint, extremely ſlender, brittle; partitions not readily diſcoverable except in the verticillated hairs. On ſubmarine rocks and ſtones. 64. C. *ciliata.* Ellis in Philoſ. Tranſ. vol 57. p. 425. tab. 18 f. 4. H.—Dillw. 53. (C. piloſa; Roth Cat. Bot. 2. 225. tab. 5. fig. 2.) " Filaments dichotomous, incurved at the tips in a forceps-like manner; partitions beſet with verticillated ciliæ, reddiſh at each end, pellucid in the middle; capſules ſomewhat globular, lateral." Filaments in buſhy tufts, ſeldom more than two inches long, varying from a bright to a purpliſh red. On rocks, ſtones, and fuci, frequent. 65. C. *equiſetifolia.* Lightf. Flor. Scot. 984.—Smith Eng. Bot. 1479.—Dillw. 54. (C. imbricata; Hudſ. Flor. Ang. 603, and multifida. Hudſ. 603, as appears from an authentic ſpecimen communicated by Dr. Goodenough to Mr. D. Turner.) " Filaments much branched; branches acuminate, elongated; branchlets verticillated, ſhort, dichotomous; joints of the branchlets long." From three to eight inches long, the thickneſs of a crow's quill, bright red when young, afterwards dull brown. *Stem* and branches every where cloathed with numerous whorled branchlets, which, being longer than the joints, are tiled upon each other, and give the plant a rough ſpongy appearance. On rocks and ſtones in the ſea, not unfrequent. 66. C. *ſpongioſa.* Hudſ. 596.—Dillw. 42. (Fucus hirſutus; Linn. Mant. 134.—Muſcus marinus hirſutus; Moriſ. 3. 650. tab. 9. fig. 6.) " Filaments branched, branchlets very ſhort, ſimple, imbricated on all ſides; joints ſhort; capſules oblong, pedicelled." Seldom more than three inches long, olive-coloured. *Branchlets* not whorled but diſpoſed without any regular order, not dichotomous. *Capſules* ſmall, on rather long pedicels, diſcharging the ſeeds at the ſummit. Rocks in the ſea, not uncommon. 67. C. *verticillata.* Lightf. Flor. Scot. p. 984.—Smith Eng. Bot. 1718.—Dillw. 55. (C. Myriophyllum; Roth in Schraber's Journ 3. 335.) " Filaments cartilaginous, variouſly branched; branchlets at the partitions, verticillated, very ſhort, incurved, frequently forked; joints about as broad as long." Four or five inches long, of a dull olive colour. On rocks and ſtones in the ſea. 68. C. *arbuſcula.* " Primary filaments thick, not jointed, naked near the bottom, much branched above; branchlets crowded, ſomewhat verticillated,

lated, ſhort, branched, jointed ; joints cylindrical, ſhort." About three or four inches long, of a beautiful deep-red brown colour when freſh, dull brown when dry without gloſs. On ſubmerſed calcareous rocks in the north of Ireland. 69. C. *cancellata.* Linn. Sp. Pl. 10. Lam. 10.—Hudſ. Flor. Ang. p. 596.—Dill. 24. tab. 4. fig. 22. "Filaments branched ; branchlets ſhort, much divided, digitate." Three or four inches long, of a pale dirty colour, irregularly branched ; branches an inch and half or two inches long ; branchlets capillary, numerous, incurved, leaving a hollow ſpace between them and the branch. On ſtones and rocks in the ſea. 70. C. *repens.* Dillw. 18. Smith Eng. Bot. 1608. (C. fulva ; Hudſ. ?) "Filaments minute, creeping, denſely matted ; partitions ſcarcely contracted ; joints cylindrical, twice as long as they are broad." Seldom more than three or four lines long, the thickneſs of human hair, of a more or leſs vivid red colour, inveſting the larger fuci and confervæ in minute denſe tufts like velvet or pluſh ; branches and branchlets generally unilateral. 71. C. *flexuoſa.* Dillw. 10. "Filaments dichotomous, rather rigid ; branches zig-gag ; branchlets generally ſimple, very ſlender, alternately unilateral, ſpreading ; joints cylindrical ; partitions obſolete." *Filaments* in cloſely entangled maſſes, from four to eight inches long, finer than human hair, pale yellowiſh green in the branchlets, very dark green in the main ſhoots. On the ſea coaſt and in ſalt-water pools at Yarmouth. 72. C. *læte virens.* Dillw. 48. "Filaments much branched, rather rigid, curved ; branchlets twice alternately unilateral ; partitions pellucid ; joints long." *Filaments* from three to ſix inches long, light green, irregularly branched, growing in a buſhy manner. On rocks, fuci, and corallines on the Welſh coaſt. 73. C. *diffuſa.* Dillw. 21. Roth Cat. Bot. 2. 207. tab. 7. "Filaments branched, diffuſe ; branches ſomewhat dichotomous, zig-zag, remote ; branchlets ſhort, approximate, obtuſe ; partitions pellucid ; joints rather long." *Filaments* in looſely entangled bundles, from two to ſix inches long, pale green, more rigid than in moſt other ſpecies, not collapſing when drawn out of the water. On rocks in the ſea. 74. C. *rupeſtris.* Linn. Sp. Pl. 20. Lam. 20. Dillw. 23. Smith Eng. Bot. 1699. (C. glauca ; Roth Cat. Bot. 2. 208. tab. 6. C. trichodes ramoſior. Dill. 28. tab. 5. fig. 29.) "Filaments much branched, faſciculated, rigid, ſtraight, obtuſe ; joints long, even ; partitions but little contracted, colourleſs." From three to ſix inches long, dull green, in denſe tufts upon rocks, pebbles, or dead ſhells. 75. C. *pellucida.* Hudſ. p. 601. Smith Eng. Bot. 1716. "Filaments erect, much branched ; branches moſtly ternate, cylindrical ; joints even, cylindrical, four times as long as broad." Filaments about ſix inches long, green, ſhining, pellucid, ſomewhat wiry and elaſtic to the touch, naked and ſtem-like towards the bottom. On the coaſt about Yarmouth. 76. C. *fœniculacea.* Hudſ. p. 594. Dill. 16. tab. 2. fig. 8. "Filaments ſquare, much branched ; branches and branchlets very long, ſcattered." *Filaments* irregularly divided like the leaves of fennel, ſoft and greeniſh when young, browniſh and ſtiffer when old. On the ſhores of Cornwal and the Iſle of Man. 77. C. *æruginoſa.* Linn. Sp. Pl. 7. Lam. 7. (C. marina capillacea brevis, viridiſſima mollis ; Dill. 23. tab. 4. fig. 20.) "Filaments branched, ſoft, ſhorter than the human finger, very green." *Filaments* numerous, very fine, ſhining and ſilky when dry, retaining their elegant cærulean green colour. On fuci, not very common. 78. C. *vagabunda.* Linn. Sp. Pl. 18. Lam. 18. (C. marina trichoides, lanæ inſtar expanſa ; Dill. 30. tab. 5. fig. 32.) "Filaments zig zag, much branched ; branchlets very ſhort, horizontal." Floating in the water without root, pale green, joints ſo ſmall towards the extremities, as ſcarcely to be ſeen with a common lens. In ſalt water marſhes and ditches. 79. C. *ſericea.* Hudſ. p. 601. (C. trichodes virgata ſericea ; Dill. 31. tab. 4. fig. 33.) "Filaments much branched, elongated ; branchlets crowded, very ſlender." From four to eight inches long, pale green in ſalt water, fine green, ſofter and ſmoother in freſh water. On ſubmarine rocks ; alſo in the new river near London and other freſh water rivulets.

††*In freſh water.*

80. C. *dichotoma.* Linn. Sp. Pl. 8. Lam. 8. Smith Eng. Bot. 932. Dillw. 15. (C. dichotoma ſetis porcinis ſimilis ; Dill. 17. tab. 3. fig. 9. Ceramium dichotomum. Roth Cat. Bot. i. 153 ;) "Filaments faſciculated, ſtraight, faſtigiate, dichotomous, hollow, ſomewhat jointed ; partitions obſolete ; joints very long, capſules elliptical, ſeſſile." *Filaments* in denſe maſſes, about two feet long, conſiderably thicker than horſe-hair, dark green, moſt dichotomous near the top ; angles of the diviſions acute ; partitions ſcarcely perceptible, except in the dried plant. *Capſules* ſcattered, ſometimes ſingle, ſometimes five or ſix together. In ditches common ; alſo according to Dillenius in ditches, between Greenwich and Woolwich, filled every tide with the brackiſh water of the Thames. 81. C. *furcata.* Hudſ. Flor. Ang p. 592. (C. capillacea, filamentis bifidis et trifidis.) "Filaments branched at the extremity ; branches ſimple." *Filaments* long, ſimple, the greateſt part of their length, once or twice branched at the end, of a dull pale colour, white when dry. 82. C. *fracta.* Flor. Dan. tab. 946. Dillw. 14. (C. divaricata ; Roth Cat. Bot. i. 179. tab. 3. fig. 1.) "Filaments much branched, matted ; branches and branchlets divaricated ; older joints oblong ; younger ones cylindrical ; capſules ſeſſile, roundiſh." *Filaments* from one to four inches long, the thickneſs of human hair, dark green, rather rigid, generally floating, in denſely entangled maſſes, on the ſurface of ſtagnant water ; branches abruptly terminated, ſo as to give the plant a broken appearance. 83. C. *vivipara.* Dillw. 59. "Filaments dichotomouſly branched ; branches zig-zag, bulbiferous at the partitions ; bulbs terminated by a long hair ; joints long ; capſules lateral, ſeſſile." *Filaments* in ſmall, ſlender, buſhy tufts, commonly not more than two lines long, never exceeding half an inch, yellowiſh green ; joints five times as long as thick. *Capſules* at ſome of the partitions ; bulbs at the others. In boggy rivulets on ſtones, moſs, and other ſubſtances. 84. C. *gelatinoſa.* Linn. Sp. Pl. 13. Lam. 13. Smith Eng. Bot. 689. Dillw. 32. (C. fontana nodoſa ſpermatis ranarum inſtar major et fuſca ; Dill. 36. tab. 7. fig. 42. Chara batrachoſperma ; Weis Gott. 33. tab. 1. Batrachoſpermum moniliforme ; Roth Cat. Bot. 2. 187.) "Filaments much branched, beaded, ſlippery ; branchlets very ſlender, pencil-ſhaped, ſomewhat verticillated, very compound, bearing the fruit ; partitions obſcure, joints rather ſhort ; capſules roundiſh with many ſeeds." From one to ſix inches long, reſembling frogs ſpawn, dark purple or yellowiſh green. β minor et viridis ; Dill. 37. tab. 7. fig. 43. δ. Hudſ. C. filamentis nodoſis et cæruleis ; Dill. fig. 43. But from ſome ſpecimens gathered in an alpine lake on Snowden, Mr. D. Turner is dubious whether it be not a diſtinct ſpecies ; its ſtems being quite hard, and its moniliform appearance very faint. In clear ſprings and ſtreams. 85. C. *mutabilis.* Roth Cat. Bot. 1. 197. Dillw. 12. Smith Eng. Bot. 1740. (C. gelatinoſa γ Hudſ. C. ſtagnalis, globulis vireſcentibus mucoſis ; Dill. 38. tab. 7. fig. 44) "Filaments much branched, gelatinous, ſomewhat beaded ; branchlets compound,

pound, tufted; partitions contracted; joints ſhort." Varying in length from half an inch to three inches, and from a light to a dark green. Main ſtems remarkably pale and pellucid; branches darker; joints ſhort. In pools and ditches, not uncommon. 86. C. *atra.* Hudſ. p. 597. Smith Eng. Bot. 692. Dillw. 11. (C. fontana, nodoſa, lubrica, filamentis tenuiſſimus nigris; Dill. 39. tab. 7. fig. 46.) "Filaments much branched, beaded, ſomewhat gelatinous; branchlets briſtle-ſhaped; joints dilated towards the tip, ciliated; ciliæ verticillated, imbricated." Varying in colour, during different ſtages of its growth, from a pale to a dark green, and finally becoming black. In clear rivulets and ſprings, but rare. 87. C *fluviatilis.* Linn. Sp. Pl. 12. Lam. Pl. Dillw. 29. (C. lubrica, ſetoſa, equiſeti facie; Dill. 39. tab. 7. fig. 47. C. nodoſa, fucum æmulans; Dill. 37. tab. 48. C. toruloſa. Roth Cat. Bot. 1. 202.) "Filaments branched, rather rigid; branches and branchlets generally alternate, attenuated each way; partitions ſwollen, tubercled; joints long, dilated at both ends." *Filaments* ſix or eight inches long, dull olive or greeniſh purple; ſometimes nearly ſimple, when they are ſhorter, thicker, and more rigid. Dill. 48. Dillwyn has ſeen theſe different filaments growing from one root. In rapid, rocky ſtreams. 88. C. *lubrica.* Dillw. 57. "Filaments much branched, ſlender, very long, ſhining, ſlippery; branches thorn-like; joints rather ſhort." *Filaments* from ſix inches to near a foot long, green, with a ſlight tinge of blue, branches ſcattered, forming an acute angle with the ſtem. In clear rivulets attached to ſtones and wood in large gelatinous maſſes. 89. C. *protenſa.* Dillw. 67. "Filaments much branched; branches diffuſe, much lengthened out, pellucid at the tip; joints rather long." *Filaments* from two lines to a half or three quarters of an inch long, light green. In rivulets and ſprings, on ſtones and aquatic plants. 90. C. *glomerata.* Linn. Sp. Pl 19. Lam. 19. Flor. Dan. tab. 651. fig. 2. Dillw. 13. (C. fontinalis ramoſiſſima glomeratim congeſta. Dill. 28. tab. 5. fig. 31. C. criſtata; Roth Cat. Bot. 1. p. 193. 2. p. 220.) "Filaments much branched; branches alternate; branchlets unilateral, faſciculated, pencil-form; partitions pellucid; joints cylindrical, rather long." *Filaments* from two or three inches to a foot long, yellowiſh green. On ſtones and wood in clear rivers and ſtreams. 91. C. *rigida.* Hudſ. Flor. Ang. 594. (C. fluviatilis fibrilloſa ſubrigida; Dill. 21. tab. 4. fig. 16.) "Filaments much branched, rather rigid; branchlets alternate, very ſhort." *Filaments* ſeveral from the ſame baſe, ſo as to have a cluſtered appearance, and ſometimes to cover the pebble to which they are attached, dull green, often inclining to brown. Somewhat hairy; branchlets moſt numerous near the ſummits of the filaments. In clear ſtreams. 92. C. *canalicularis.* Linn. Sp. Pl. 4. Lam. 4. (C. rivulorum capillacea denſiſſime congeſtis ramulis; Dill. 21. tab. 5. fig. 15.) "Filaments moſt branched near the baſe; branches long." *Filaments* one or two inches long, ſlender, deep green, ſimple or but little branched above the middle, of a ſpongy ſoft ſubſtance, denſely matted together ſo as to reſemble a piece of velvet, ſoft and herbaceous when freſh, but when dry blackiſh, and acquiring almoſt a ſtony hardneſs from the mud adhering to it. In pure ſtreams and mill-pond water ſpouts. 93. C. *bulloſa.* Linn. Sp. Pl. 3. Lam. 3. (C. paluſtris bombycina; Dill. 18. tab. 3. fig. 11. "Filaments branched, matted, incloſing air bubbles." *Filaments* from three to nine inches or a foot long, ſlender, dull yellowiſh green. In clear waters, ſoft, ſomewhat ſilky, and of a livelier green; in ſtagnant muddy waters, paler, tomentous, reſembling dirty cotton. Profeſſor Martens is of opinion that C. fracta is the plant intended by Linnæus, and ſince called C. bulloſa; but Mr. Dillwyn obſerves that the ſpecimen in Dillenius's herbarium, here deſcribed, is certainly another ſpecies, and agrees with Mr. D. Turner in thinking, that ſeveral diſtinct plants which have the property of retaining bubbles of air have been confounded by authors, and conſequently that the confervæ bulloſæ are a family and not a ſpecies. Theſe confervæ when dried have been uſed as wadding for ſtuffing garments, and have been woven into coarſe houſehold linen. 94. C. *diſtorta.* Flor. Dan. tab. 820. Dillw. 22. "Filaments branched, jointed, faſciated with tranſverſe lines; branches and branchlets diſtorted; partitions obſolete; joints ſhort." *Filaments* about half an inch long, extremely ſlender, of a beautiful dark green colour varying to a lighter colour as they approach to decay; branches ſeldom numerous, but with a very peculiar twiſt at their ramifications. Paraſitical in ſhort thick tufts on decaying graſs, attached to ſmall pieces of which it frequently floats on the ſurface of the water. Hitherto found in Great Britain, only by Mr. Dillwyn, in a boggy pool on Sketty Burroughs, near Swanſea. 95. C. *ægagropila.* Linn. Sp. Pl. 21. Lam. 21. Smith Eng. Bot. 1377. Dillw. 87. "Filaments much branched, cluſtered into a globe and divaricating from the centre; branches and branchlets nearly unilateral, ſtraight, obtuſe; joints long, cylindrical." From the ſize of a pea to three or four inches in diameter, always pretty exactly ſpherical, hollow within, without any ſolid body, or root, to which the filaments might originally have been attached. The ſpecific name alludes to the hairy balls found in the ſtomach of goats. In lakes lying in great abundance at the bottom of the water. 96. C. *nana.* Dillw. 30. "Filaments branched, very minute; branches and branchlets generally alternate, acuminate; partitions pellucid; joints cylindrical." *Filaments* ſeldom much more than half a line long, of a pale brown colour tinged with brown, reſembling C. littoralis in its ramification, and remarkably acuminate branches. Paraſitical on decayed confervas, &c. in rocky rivers. 97. C. *typhloderma.* Dillw. 83. "Filaments nearly ſimple, denſely matted; partitions obſcure; joints ſhort." The extreme tenuity and entangled growth of the filaments makes it impoſſible to aſcertain their length; their colour is a dull olive green. Obſerved in a bottle which contained a ſolution of gum dragon in water, the ſurface of which was covered with a maſs of filaments ſo denſely interwoven as to form a film about two lines in thickneſs, bearing a conſiderable reſemblance to the ſkin of a mole. 98. C. *ochracea.* Dillw. 62. Roth Cat. Bot. 1. 65. tab. 5. fig. 2. "Filaments much branched, very ſlender, very brittle, cloſely compact, conſtituting an ochraceous jelly, which at length breaks into fragments of ſeparate filaments." The filaments are ſo extremely fragile that the ſlighteſt touch or any conſiderable agitation of the water breaks them into a thouſand pieces, which at firſt remain ſuſpended, and afterwards ſink to the bottom in the form of an ochraceous powder. In this ſtate only can the plant be examined, but the fragments are ſo ſmall that it is impoſſible to aſcertain their original length, and under the higheſt magnifiers their thickneſs ſcarcely ſeems equal to that of the human hair. In pools and ditches common, of a dull yellow colour. 99. C. *lactea.* Dillw. 79. Roth Cat. Bot. 1. p. 216. 3. p. 292. (C. puſilla; Roth Flor. Germ. 1. 524.) "Filaments much branched, gelatinous, ſlippery; branches rod-like, alternate from each partition; partitions contracted; joints very long, glaſſy-tranſparent." *Filaments* growing in gelatinous maſſes at the bottom of ditches and rivulets, from half an inch to three or four inches long, of a dirty white colour; branches cluſtered, ſo as to give them a bruſh-like appearance; partitions of a duſky colour. *Joints* at leaſt ten times longer than thick. 100. C. *myochrous.* Dillw. 19. Smith Eng. Bot. 1555. "Filaments very denſely matted, branched; branchlets ſimple, generally unilateral, in pairs, incurved." *Filaments* ſometimes quite ſimple, generally branched, ſeldom more than half an inch long, as fine as the fineſt wool. On the rocky beds of torrents in the vale of Beddgelert, in Caernarvonſhire, matting the ſtones with a velvety covering, three or four lines in diameter, of a dark gloſſy brown colour, ſoft to the touch, which, when taken out of the water, might be compared to the ſkin of a mouſe. 101. C. *veſicata.* Dillw. 74. Muller in Nov. Act. Pet. 3. "Filaments branched, ſomewhat jointed, rigid: veſicles innate, ſolitary, elliptical, broader than the filament; capſules generally in pairs, pear-ſhaped on ſhort peduncles." *Filaments* in buſhy maſſes at the bottom of the water, ſo extremely brittle that their length cannot eaſily be aſcertained, yellowiſh green, cylindrical, filled with minute granules which iſſue from them when broken; very rough to the touch; branches few, diſtant, generally making an obtuſe angle with the ſtem. *Stems* and *branches* frequently ſwollen, with bladder-like veſicles, four or five times thicker than the filaments, reſembling thoſe of fucus nodoſus. *Partitions* irregularly diſpoſed, always at a great diſtance from each other. 102. C. *amphibia.* Linn. Sp. Pl. 5. Lam. 5. Dillw. 41. (C. amphibia fibrilloſa et ſpongioſa; Dill. 22. tab. 4. fig. 7. B and C). "Filaments ſomewhat jointed, branched, denſely matted; branches ſpreading, remote; branchlets, when not immerſed, collecting into ſharp briſtly points; partitions but little contracted; capſules ſeſſile, ſomewhat elliptical." β. branches elongated (C. furcata; β. Hudſ. Ceramium coeſpitoſum; Roth Cat. Bot. 1. p. 154. 2. p. 186. C. paluſtris filamentis brevioribus et craſſioribus; Dill. 17. tab. 3. fig. 10.) Filaments very various in length, according to the ſituation, bright green, becoming aſh-coloured with age; α is the plant as it grows on the edges of ditches, and in ſhallow water, where it is not wholly immerſed. In ſuch ſituations, it frequently occurs in maſſes, ſo denſely matted as to hold water like a ſponge, with its ſurface beſet by erect branches, which give it a briſtly appearance. In floods, when the waters overflow the plant, the length of the filaments is gradually increaſed, and forms Mr. Dillwyn's β; but when the waters ſubſide, the filaments, again expoſed to air, take of courſe an horizontal direction, and again throw out erect ſpreading branchlets, which, on being dried, collapſe ſo as to form rather ſtiff points. In rivers, the branches are frequently carried out by the force of the ſtream to a great length, and in that caſe do not aſſume a briſtly appearance when expoſed to air; probably owing to the leſs ſpongy nature of the maſs, in conſequence of which the water is not ſo readily tranſmitted to the upper ſurface, as to enable it to make freſh ſhoots. The plant has a mouldy ungrateful ſmell, and is much uſed as a ſhelter by aquatic inſects.

* * *Not immerſed.*

103. C. *atro-virens.* Dillw. 25. "Filaments rather rigid, branched; branches divaricated, ſomewhat unilateral, attenuated at both ends, rather obtuſe; partitions pellucid; joints very ſhort, marked with three points." *Filaments* from a quarter to half an inch long, growing in thick buſhy tufts, of a blackiſh green colour, not unfrequently intermixed with muſci. On the wet rocks, forming the banks of the river Dylais, near Neath. 104. C. *frigida.* "Filaments not jointed, creeping, branched; Dillw. 16. (Ceramium Dillwynii; Roth.) "Filaments not jointed, creeping, branched; branches alternate; capſules ſeſſile, round." *Filaments* about an inch long, a little finer than human hair, of a pale green colour, growing in looſe irregular patches, two or three inches in diameter, very ſlightly adhering to the ſoil. On the ground in moiſt ſhady places, particularly in turnip fields, with a northern expoſure, during the winter and early months of ſpring. The frigida of Dr. Roth is a different plant, referred by him to Dill. tab. 4. fig. 17, A. 105. C. *umbroſa.* Dillw. 61. Roth Cat. Bot. 1. 191. tab. 4. fig. 3. (C. arenaria; Roth Cat. Bot. 2. 217?) "Filaments branched, creeping, fragile, ſhort-obtuſe; branches curved, ſimple, ſomewhat unilateral: joints long, ſometimes cylindrical, ſometimes inflated." Growing in ſmaller patches, and of a darker colour, than C. frigida. *Filaments* ſcarcely half an inch long; joints varying greatly in ſhape and length. 106. C. *pallida.* Dillw. 78. "Filaments dichotomous, curved, zig-zag, faſtigiate angles of the diviſions roundiſh; joints very long." *Filaments* conſiderably finer than human hair, a light yellowiſh brown, matted together into denſe leathery maſſes, about an inch long, and the thickneſs of a ſhilling; joints at leaſt eight or ten times broader than thick. Found on ſome yellow ochre, in a pot of iſinglaſs ſize. 107. C. *multicapſularis.* Dillw. 71. "Filaments minute, creeping, olive-coloured; branches erect, generally ſimple, ſhort, thickened towards the top, and bearing the capſules; capſules cluſtered, ſpherical." *Filaments* very minute, thickly entangled, growing in ſmall irregular patches. *Joints* in the creeping ſtem very long; in the branches ſhorteſt at the baſe, and longeſt towards the ſummit. *Capſules* terminating the branches, diſcharging the ſeeds at the orifice. On clayey banks, in high expoſed ſituations. 108. C. *rubiginoſa.* Dillw. 72. Smith Eng. Bot. 1701. "Filaments creeping, branched, entangled, alternately bipinnate; branches divaricated, tapering, acute; joints elongated, cylindrical." *Filaments* creeping in looſe entangled maſſes, among moſſes, over dead ſtalks and ſticks, and along the ground, of a brown cheſnut colour; branches from a quarter to half an inch long; pinnæ and pinnulæ variouſly curved, nearly at right angles with the ſtem and branches; partitions almoſt black; joints in the ſtem and main branches three or four times longer than broad. On hedge banks. 109. C. *rubiginoſa.* Dillw. 68. "Filaments much branched, rigid, rather erect; branches zig-zag, ſpreading, matted together ſo as to form nearly a ſolid maſs; joints long." *Filaments* very minute, growing in irregular patches, about an eighth of an inch in thickneſs, of a ruſty brown colour, entirely deſtitute of gloſs. *Joints* viſible only under the higheſt powers of the microſcope, about four times longer than broad. On rotten wood, ſecluded from the light. 110. C. *velutina.* Dillw. 77. Smith Eng. Bot. 1556. "Filaments creeping, branched, matted; branches erect, alternate, or unilateral, curved, obtuſe; joints ſlightly ſwelling, at leaſt twice as long as broad." Diſtinguiſhed by its ſweet ſcent. (See Byssus *volutina.*) Jointed ſtructure firſt diſcovered by Mr. J. D. Sowerby. 111. C. *aurea.* Dillw. 35. "Filaments branched, gold-coloured, minute; branches long, ſpreading, rather rigid, ſomewhat incurved; partitions pellucid; joints longiſh." (See Byssus *aurea.*) Jointed ſtructure, firſt diſcovered by Mr. Dillwyn. 112. C. *purpurea.* Dillw. 43. "Filaments dichotomous, flexible, minute; dichotomous, branches approximate; partitions obſcure; joints longiſh." (See Byssus *purpurea.*) 113. C. *lichenicola.* Smith Eng. Bot. 1609. "Filaments red, upright, crowded, alternately branched; roughiſh; joints ſwelling, about as long as broad." *Filaments* ſcarcely a line long, forming thick tufts, and appearing to the naked eye like brick-duſt. Paraſitical on cruſtaceous

lichens. 114. C. *muſcicola.* Smith Eng. Bot. 1638. "Filaments ruſty brown, upright, crowded, much and irregularly branched; joints cylindrical, twice as broad as long." *Filaments* two or three lines long, crooked, divaricated, of equal thickneſs throughout, gloſſy, like human hair under a microſcope; branches aſcending, obtuſe, frequently unilateral. Paraſitical on orthotricum ſtriatum.

Obſ. The term confervæ occurs, we believe, firſt in the Natural Hiſtory of Pliny, and was applied by him to a freſh water ſpecies of the preſent genus. The name was extended to two or three ſpecies by the elder modern botaniſts. But this part of the ſcience was not at all ſtudied before the time of Dillenius, who, in his admirable "Hiſtoria Muſcorum," has deſcribed and figured forty-eight ſpecies, partly marine, and partly growing in freſh water. Theſe he has diſtributed under three *orders*, as he calls them, *viz.* 1. Equabili filo protenſæ ſeu non geniculatæ. 2. Geniculatæ; and, 3. Nodoſæ; dividing the firſt order into ſimple and branched; ſucceeding authors, for a conſiderable time, ſeem to have ſuppoſed that Dillenius had exhauſted the ſubject. Linnæus has given only twenty-one ſpecies, adding only C. ægrapopila to thoſe which are already deſcribed by that great cryptogamiſt, omitting ſuch as he was not able to identify, and conſidering ſome as mere varieties. La Marck, in Encyclopedie Methodique, has done nothing more than copy the Linnæan ſpecies, in exactly the ſame order. Hudſon, in the ſecond edition of his "Flora Anglica," has introduced ſeveral ſpecies, not known either to Dillenius or Linnæus. Lightfoot, in his "Flora Scotica," has alſo made one or two additions. But it is not more than ſix or ſeven years ſince rapid advances have begun to be made in the knowledge of confervæ. Mr. D. Turner and Mr. Dillwyn are now diligently employed in the inveſtigation of the Britiſh ſpecies; ſeveral foreign botaniſts, profeſſor Roth in particular, are ſucceſsfully engaged in the ſame purſuit; and we are informed by Boſc, in "Nouveaux Dictionaire d'Hiſtoire Naturelle," that profeſſor Draparnaud of Montpellier is now buſy in preparing a Monographia Confervarum, and has already determined ſeveral hundred ſpecies. We have been induced to confine ourſelves, with a ſingle exception, to the Britiſh ſpecies; partly by our inability to procure all the works which are neceſſary for a complete account of what has hitherto been done by foreign botaniſts; but chiefly by the conſideration, that the ſpecies which belong to the Flora of the Britiſh iſlands, are the only ones acceſſible to the greater part of our readers. Our knowledge of theſe plants is indeed ſtill very imperfect, and no generic character has yet been formed, which is ſufficiently diſcriminating and comprehenſive. The jointed ſtructure of the filaments has generally been conſidered as an eſſential character; but we have been led by the high authority of Mr. Dillwyn to admit one ſpecies (n. 104.) which has not this conformation. We have already ſeen that the fructification of ſeveral ſpecies does not conſiſt of *cloſed tubercles*, as it is deſcribed even in Dr. Smith's laſt improved generic character, but of *capſules opening* at the apex, and diſcharging the ſeeds in a manner ſimilar to that obſerved in many fuci. Theſe have been ſeparated by Dr. Roth into a diſtinct genus which he calls ceramium; and it is probable that further reſearches will prove the propriety of making other ſeparations. M. Vaucher of Geneva thinks, that he has diſcovered five different modes of propagation in the plants uſually called confervæ; which has induced Decandolle to form them into ſix genera. *Conferva.* Filaments cartilaginous or herbaceous, divided by partitions; ſeeds encloſed between the partitions, and not eſcaping but by the deſtruction of the tube itſelf. *Ceramium.* Filaments membranous, cartilaginous, without partitions; capſules monoſpermous, adhering to the external ſurface of the filaments. *Vaucheria.* Filaments herbaceous, ſimple or branched, without partitions; ſeeds attached to the exterior ſide of the filaments, and generally peduncled. *Batrachoſpermum.* Filaments knotty, jointed, gelatinous; knots formed of filaments, ſimple or compound, between which are found ſeeds or ſhoots (cayeux) detaching themſelves, and conſiſting of filaments already jointed. *Chantrania.* Filaments ſolid, knotty; knots ſeparating and becoming new plants, in the way of ſlips or cuttings. *Hydrodyctium.* Tube cylindrical, cloſed at the two extremities, and anaſtomiſing into pentagonal meſhes; filaments of the pentagon ſwelling at their extremities, ſeparating and becoming themſelves cylindrical tubes, cloſed at the ends, and compoſed of pentagon meſhes. The laſt three genera, according to his ideas, have no proper ſeeds.

See ſome curious experiments by Dr. Prieſtley on a ſpecies of conferva or water-moſs of a peculiar kind, the manner of its production, and its effect, by the concurring action of light upon it, in dephlogiſticating or depurating the air to which it has acceſs, and thereby increaſing the quantity of it; in "Obſervations on Air," vol. iv. p. 335, &c. vol. v. § 2, 3, 4, 5. The ſeeds of this plant, ſays Dr. Prieſtley, float every where; in the air, on the earth, on the ſea, on the Alps, in the plains, under the poles and the equator, in ſummer and winter, and in all ſeaſons; and they are received into the water, inſinuating themſelves into veſſels of water through the ſmalleſt apertures, where they germinate. Dr. Ingenhouſz made a variety of experiments on this ſingular ſubſtance; from which he concludes, that the water itſelf, or ſome ſubſtance in the water, is converted into this kind of vegetation. It is a real tranſmutation, which may appear incomprehenſible to the philoſopher, but which, in reality, is not more extraordinary than the change of graſs and other vegetables into greaſe in the bodies of granivorous animals, and the change of the aqueous juice of the olive into oil. Dr. Prieſtley, however, obſerves, that the change of water into an organized plant is a thing of a very different nature from theſe, and tends to revive the long exploded doctrine of equivocal or ſpontaneous generation. Dr. Girtanner of Gottingen (ſee Annales de Chemie, No. 100.) traces its formation from azot, which is a conſtituent principle of bodies, in the following manner. When water is expoſed to the ſun the light decompoſes it, and diſengages the oxygen in a large quantity. The hydrogen then retains the laſt portions of the oxygen; azot is formed, and announces itſelf by its green colour; the water is more and more decompoſed; more of the oxygen, which, in the opinion of this writer, is the principle of life and irritability in organized nature, becomes fixed; and this azot, produced from water by means of the ſun, is an organized body, the "conferva fontinalis;" a plant which lives, expands, and perpetuates its ſpecies. The influence of the ſolar light is, he conceives, abſolutely neceſſary for this converſion of water into a plant or organized azot. No degree of heat can ſupply its place. Mr. Senger of Reek, in Weſtphalia, has lately diſcovered, that the conferva affords next to ſage, one of the fitteſt materials for the making of paper; in conſequence of which he obtained the honour of a gratuity from the court of Berlin, and alſo a patent for the manufacture of paper from this ſubſtance. From his experiments it likewiſe appears, that the conferva, after a previous preparation, might be made a ſubſtitute for cotton-wool, and a ſuccedaneum for feathers in beds.

CONFESS *and avoid*, in *Law*, a ſpecies of REPLICATION, in which the plaintiff introduces ſome new matter or diſtinction, conſiſtent with his former declaration; as, in an action of treſpaſs upon lands of which the plaintiff is ſeiſed; if the defendant ſhews a title to the land by deſcent, the plaintiff may either deny the fact, or *confeſs and avoid* it, by replying, that ſuch deſcent happened, but that the defendant hath ſince demiſed the lands to the plaintiff for the term of life. Blackſt. Com. vol. iii. p. 310.

CONFESSION, CONFESSIO, in *Rhetoric*, the ſame with what is otherwiſe called PARHOMOLOGY.

CONFESSION, in a *Civil Senſe*, a declaration or acknowledgment of ſome truth, though it be againſt the intereſt of the party who makes it; whether it be in a court of juſtice, or out of it. It is a maxim, that in civil matters, the confeſſion is never to be divided, but always taken entire; and that a criminal is never condemned on his ſimple confeſſion, without other collateral proofs; nor is a voluntary extra-judicial confeſſion admitted as any proof. A perſon is not admitted to accuſe himſelf, according to that rule in law, *non auditer perire volens*.

CONFESSION *of Action*, in *Law*, is a ſpecies of plea to the action, in which the merits of the complaint are anſwered, by confeſſing either wholly, or, which is moſt common, in part. A confeſſion of the whole complaint is not very uſual, for then the defendant would probably end the matter ſooner; or not plead at all, but ſuffer judgment to go by default. Yet ſometimes, after tender and refuſal of a debt, if the creditor haraſſes his debtor with an action, it then becomes neceſſary for the defendant to acknowledge the debt, and plead the tender; adding that he has always been ready, "tout temps priſt," and ſtill is ready, "uncore priſt" to diſcharge it: for a tender by the debtor, and refuſed by the creditor, will, in all caſes, diſcharge the coſts, (1 Ventr. 21.) but not the debt itſelf; though in ſome particular caſes the creditor will totally loſe his money. (Litt. § 338. Co. Litt. 209.) But frequently the defendant confeſſes one part of the complaint (by a "cognovit actionem" in reſpect of it,) and traverſes or denies the reſt; in order to avoid the expence of carrying that part to a formal trial, which he has no ground to litigate. A ſpecies of this ſort of confeſſion is "the payment of money into court;" which is for the moſt part neceſſary upon pleading a tender, and is itſelf a kind of tender to the plaintiff; by paying into the hands of the proper officer of the court as much as the defendant acknowledges to be due, together with the coſts hitherto incurred, in order to prevent the expence of any farther proceedings. This may be done upon what is called a "motion;" which is an occaſional application to the court by their parties or their counſel, in order to obtain ſome rule or order of court, which becomes neceſſary in the progreſs of a cauſe; and it is uſually grounded upon an "affidavit" (the perfect tenſe of the verb "affido") being a voluntary oath before ſome judge or officer of the court, to evince the truth of certain facts, upon which the motion is grounded: though no ſuch affidavit is neceſſary for payment of money into court. If, after the money paid in, the plaintiff proceeds in his ſuit, it is at his own peril; for, if he does not prove more due than is ſo paid into court, he ſhall be non-ſuited and pay the defendant's coſts; but he ſhall ſtill have the money ſo paid in, for that the defendant has acknowledged his due. Blackſt. Com. vol. iii.

CONFESSION *of Indictment*, is a priſoner's acknowledgment of the offence, when he is brought to the bar to be arraigned: upon a ſimple and plain confeſſion, which the court is backward in receiving and recording, nothing remains but to award judgment. This confeſſion is made before the judge; in conſequence of which, the priſoner ſubmits to the legal penalty annexed to his crime; or the priſoner, by confeſſion, becomes an approver, or accuſer of others. See APPROVEMENT.

There was alſo a third ſort of confeſſion, formerly made by an offender in felony, not in court before the judge, but before the coroner in a church, or other privileged place, upon which the offender, by the ancient law of the land, was to abjure the realm. 3 Inſt. 192. See ABJURATION.

There is alſo a confeſſion indirectly implied, as well as directly expreſſed, in criminal caſes; as if the defendant, in a caſe not capital, doth not directly own himſelf guilty of the crime, but by ſubmitting to a fine owns his guilt; upon which the judge may accept of his ſubmiſſion to the king's mercy. (Lamb. lib. iv. c. 9.) By this indirect confeſſion, the defendant ſhall not be barred to plead "Not guilty" to an action, &c. for the ſame fact; the entry of it is, that the defendant "puts himſelf on the king's mercy;" and of the direct confeſſion, "that he acknowledges the indictment." This laſt confeſſion carries with it ſo ſtrong a preſumption of guilt, that being entered on record, on indictment of treſpaſs, it ſtops the defendant to plead "Not guilty" to an action brought afterwards againſt him for the ſame matter: but ſuch entry of a confeſſion of an indictment of a capital crime, it is ſaid, will not ſtop a defendant to plead "Not guilty" to an APPEAL, it being in caſe of life. And where a perſon upon his arraignment actually confeſſes himſelf guilty, or unadviſedly diſcloſes the ſpecial manner of the fact, ſuppoſing that it doth not amount to felony, where it doth; the judges, upon probable circumſtances, that ſuch confeſſion may proceed from fear, weakneſs, or ignorance, may refuſe it, and ſuffer the party to plead "Not guilty". 2 Hawk. P. C. c. 31. § 2.

A confeſſion may be received, and the plea of "Not guilty" be withdrawn, though recorded. (Kel. 11.) The confeſſion of the defendant, whether taken upon an examination before juſtices of peace, in purſuance of the 1 and 2 P. & M. c. 13. or 2 and 3 P. & M. c. 10. upon an offender's being bailed or committed for felony; or taken by the common law, upon an examination before a ſecretary of ſtate, or other magiſtrate, for treaſon or other crimes, is allowed to be given in evidence againſt the party confeſſing; but not againſt others. Alſo two witneſſes of a confeſſion of high treaſon, upon an examination before a juſtice of peace, were ſufficient to convict the perſon ſo confeſſing, within the meaning of 1 Ed. VI. c. 12. and 5 & 6 Ed. VI. c. 11. which required two witneſſes in high treaſon; unleſs the offender ſhould willingly confeſs, &c. But the ſtat. 7 W. c. 3. requires two witneſſes, except the party ſhall *willingly*, without violence, confeſs, &c. *in open court*. 2 Hawk. P. C. c. 41. § 3.

A demurrer amounts to a confeſſion of the indictment as laid, ſo far, that if the indictment be good, judgment and execution ſhall go againſt the priſoner. (Bro. 86. S. P. C. 150. H. P. C. 246.) And in criminal caſes, not capital, if the defendant demurs to an indictment, &c. whether in abatement, or otherwiſe, the court will not give judgment againſt him to anſwer over, but final judgment. (2 Hawk. c. 32. § 7.) See ABATEMENT. Where a priſoner confeſſes the fact, the court has nothing more to do than to proceed to judgment againſt him. "Confeſſus in judicio pro judicato habetur." 11 Rep. 30. 4 Inſt. 66. 2 Hawk. P. C. c. 32.

CONFESSION, in *Theology*, denotes the verbal acknowledgment which a penitent makes of his ſins to God: in a more partial and reſtricted ſenſe, it is a declaration of a perſon's ſins, made to a prieſt, in order to obtain abſolution for the ſame. The Romiſh church makes confeſſion a part of the ſacrament of penance.

Confeſſion was anciently public and general, in the face of the church; though the Romaniſts have ſince altered it, and made it private and auricular.

Confeſſions are to be buried in eternal ſilence, under pain of the greateſt puniſhment to the prieſt who reveals them. Bellarmin, Valentia, and ſome other Romiſh controverſial writers, endeavour to trace up auricular confeſſion to the earlieſt ages; and thus contend for a point given up by the reſt. M. Fleury owns, that the firſt inſtance of auricular confeſſion he can meet with, is that of St. Eloi, who, being grown old, made a confeſſion to a prieſt of all his ſins from his youth upwards.

Secret confeſſion was firſt decreed and eſtabliſhed in the 4th council of Lateran, under Innocent III., in 1215, cap. 21. And the decree of this council was afterwards confirmed and enlarged in the council of Florence, and in that of Trent (ſeſſ. 14. cap. 5.), which expreſsly ordains, that confeſſion was inſtituted by Chriſt, and that by the law of God it is neceſſary to ſalvation; and that it has been always practiſed in the Catholic church. Hard. Concil. tom. vii. p. 35. and tom. x. p. 92. See POPERY.

The Indians, according to Tavernier, have a kind of confeſſion; and the ſame may be ſaid of the Jews: theſe laſt have formulas for thoſe who are not capable of making a detail of all their ſins: the ordinary form is in alphabetical order, each letter containing a capital ſin. This they uſually rehearſe on Mondays and Thurſdays, and on faſt-days, and other occaſions; ſome every night and morning. When any of them find themſelves near death, they ſend for ten perſons, more or leſs, one of them a rabbin; and in their preſence recite the confeſſion. See Leo de Modena.

CONFESSSION *of faith*, denotes a liſt, or enumeration and declaration of the ſeveral articles of belief, in a church. See ARTICLES *of faith*.

In the council of Rimini, the Catholic biſhops found fault with dates in a confeſſion of faith, and obſerved that the church never uſed to date them.

CONFESSION, *Augſburg* or *Auguſtan*. See AUGUSTAN *Confeſſion*.

CONFESSIONAL, or CONFESSIONARY, in *Church Hiſtory*, a place in churches, uſually under the main altar, wherein were depoſited the bodies of deceaſed ſaints, martyrs, and confeſſors.

CONFESSIONAL is alſo uſed in the Romiſh church for a little box, or deſk in the church, where the confeſſor takes the confeſſions of the penitent.

CONFESSO, *Pro*-CONFESSO. See PRO-CONFESSO.

CONFESSOR, a Chriſtian, who has made a ſolemn, and reſolute profeſſion of the faith, and has endured torments in its defence. A mere ſaint is called a confeſſor, to diſtinguiſh him from the roll of dignified ſaints; ſuch as *apoſtles*, *martyrs*, &c.

The title of confeſſors was given in the early ages of the church, and particularly towards the commencement of the firſt century of the Chriſtian æra, to thoſe, who, in the face of death, and at the expence of honour, fortune, and all the other advantages of the world, had confeſſed with fortitude, before the Roman tribunals, their firm attachment to the religion of Jeſus.

In eccleſiaſtical hiſtory we frequently find the word confeſſors uſed for martyrs; in after-times, it was confined to thoſe who, after having been tormented by the tyrants, were permitted to live and die in peace. And at laſt it was alſo uſed for thoſe who, after having lived a good life, died under an opinion of ſanctity. According to St. Cyprian, he who preſented himſelf to torture, or even to martyrdom, without being called to it, was not called a *confeſſor*, but a *profeſſor*: and if any out of a want of courage abandoned his country, and became a voluntary exile for the ſake of the faith, he was called *exterris*.

The veneration that was paid to both martyrs and confeſſors in the early ages of the Chriſtian church is hardly credible. The diſtinguiſhing honours and privileges they enjoyed, the authority with which their counſels and deciſions were attended, would furniſh ample matter for an intereſting hiſtory. Without doubt it was both wiſe and juſt to treat with reſpect, and to inveſt with extraordinary privileges, thoſe Chriſtian heroes, ſince nothing was more adapted to encourage others to ſuffer with chearfulneſs in the cauſe of Chriſt. Nevertheleſs, as the beſt and wiſeſt inſtitutions were generally perverted by the weakneſs or corruption of men, from their original purpoſe; ſo the authority and privileges granted, in the beginning, to martyrs and confeſſors, became, in proceſs of time, a ſupport to ſuperſtition, an incentive to enthuſiaſm, and a ſource of innumerable evils and abuſes. See MARTYR.

CONFESSOR is alſo a prieſt, in the Romiſh church, who has a power to hear ſinners in the ſacrament of penance, and to give them abſolution. See SHROVE-TIDE.

The church calls him in Latin *confeſſarius*, to diſtinguiſh him from *confeſſor*, which is a name conſecrated to ſaints. The confeſſors of the kings of France, from the time of Henry IV. have been conſtantly Jeſuits: before him the Dominicans and Cordeliers ſhared the office between them. The confeſſors of the houſe of Auſtria have alſo, ordinarily, been Dominicans and Cordeliers; but the latter emperors have all taken Jeſuits.

CONFESSOR *to his Majeſty*. See CLERK *of the cloſet*.

CONFIDENCE, in *Military Language*, denotes a firm reliance on the ſkill, courage, conduct, &c. of an individual. It is of the firſt importance for the commander of an army to have the entire confidence of the officers and ſoldiers under his command. This was remarkably the caſe with Hannibal, Julius Cæſar, &c. among the ancients, and with the marſhal de Turenne, John duke of Marlborough, &c. among the moderns. A general, in whom his troops have confidence, may gain a victory without employing much military ſkill; and on the other hand, the moſt ſkilful general may loſe one, who has loſt the confidence of his army.

CONFIGURATION, the exterior ſurface, that bounds bodies, and gives them their particular figure.

That which makes the ſpecific difference between bodies, is the different configuration, and the different ſituation of their parts. A ſhort, or a long ſight, depend on the different configuration of the cryſtalline.

CONFIGURATION *of the planets*, in *Aſtronomy* and *Aſtrology*, is a certain diſtance or ſituation of the planets in the zodiac, whereby they are ſuppoſed to aid, or oppoſe each other. See ASPECT and SATELLITES.

CONFIGURATIONS *of ſalts*, a term uſed by ſome to expreſs the combinations of the particles of the ſalts of plants, and other ſubſtances, into certain figures, on evaporating the water in which they had been diſſolved, ſo haſtily as not to admit of their ſhooting into their own regular cryſtals. See CRYSTALLIZATION.

CONFINEMENT *to the realm*. See NE *exeat regnum*.

CONFIRMATION, in a general ſenſe, the act of ratifying or rendering a title, claim, pretenſion, report, or the like, more ſure and indiſputable.

CONFIRMATION, in *Law*, denotes the conveyance of an eſtate, or right *in eſſe*, which a perſon hath in or to lands, &c. from one man to another that hath the poſſeſſion or ſome eſtate in it, whereby a voidable eſtate is made ſure and unavoidable, or a particular eſtate is increaſed, or poſſeſſion made perfect: and it is particularly uſed for the ſtrengthening or homologating an eſtate of one already in poſſeſſion of it by a voidable title. Thus, if a biſhop grant his chancellorſhip by patent, for term of the patentee's life; this is no void grant: yet it is avoidable by the biſhop's death, except it be ſtrengthened alſo by the confirmation of the dean and chapter. 1 Inſt. 295.

CONFIRMATION is alſo defined to be the approbation or aſſent to an eſtate already created: which as far as it is in the power of the confirmer, makes it good and valid; ſo that the confirmation doth not regularly *create an eſtate*, yet ſuch words may be blended in the confirmation as may create and enlarge an eſtate; but this takes place by the force of ſuch words as are foreign to the buſineſs of confirmation, and by their own force and power, tend to create the eſtate. Gilb. Ten. 75. A confirmation, ſays judge Blackſtone, is of a nature nearly allied to a releaſe; and the words of making it are theſe "have given, granted, ratified, approved, and confirmed." (Litt. § 515. 531.) An inſtance of the firſt branch of the above definition is, if tenant for life leaſeth for 40 years, and dieth during that time; here the leaſe for years is voidable by him in reverſion; yet, if he hath confirmed the eſtate of the leſſee for years, before the death of the tenant for life, it is no longer voidable but ſure. (Litt. § 516.) The latter branch, or that which tends to the increaſe of a particular eſtate, is the ſame in all reſpects with that ſpecies of releaſe, which operates by way of enlargement.

Madox ſays, that moſt ancient confirmations, made after the conqueſt, often run like feoffments; and are diſtinguiſhable from them, chiefly by ſome words inſerting a former feoffment or grant. In former times, when feoffees were frequently diſſeiſed of their lands upon ſome ſuggeſtion or other, charters of confirmation ſeem to have been in great requeſt. Poſſeſſors of lands, &c. ſeemed not to have thought themſelves ſecure againſt the king, or the great lords who were their feoffors, or in whoſe lands their fees lay, unleſs they had repeated confirmations from them, their heirs or ſucceſſors. And theſe ancient confirmations ſeem to have been ſometimes made, either by precept or writ from the king, or other lords, to put the feoffees, or their heirs or ſucceſſors into ſeiſin, after they had been diſſeiſed, or to keep them in their ſeiſin undiſturbed, or elſe by charter of expreſs confirmation. Confirmation is "*perficiens, creſcens*, or *diminuens*:" *perficiens*, as if feoffee upon condition make a feoffment, and the feoffor confirm the eſtate of the ſecond feoffee;—*creſcens*, which always enlarges the eſtate of a tenant; as tenant for years to hold for life, &c.;—and *diminuens*, as when the lord of whom the land is holden, confirms the eſtate of his tenant, to hold by a leſs rent. 9 Rep. 142.

The lord may diminiſh the ſervices of his tenant by confirmation; but not reſerve new ſervices, ſo long as the former eſtate in the tenancy continues; and therefore if he confirm to the tenant, to yield him a hawk, &c. yearly, it is void. (Litt. § 539. 1 Co. Inſt. 296.) Leaſes for years may be confirmed for part of the term, or for part of the land, &c.; but an eſtate of freehold, being entire, cannot be confirmed for part of the eſtate. (5 Rep. 81.) There may be a confirmation implied by law, as well as expreſs by deed; where the law by conſtruction confirms a grant made to another purpoſe: and a confirmation may enlarge an eſtate, from an eſtate held at will to term of years, or a greater eſtate, from an eſtate for years to an eſtate for life; from an eſtate for life, to an eſtate in tail, or in fee; and from an eſtate in tail to an eſtate in fee-ſimple. (1 Inſt. 305. 9 Rep. 142. Dyer. 263.) But if the confirmation be made to leſſee for life or years, of his term or eſtate, and not of the land, this doth not increaſe the eſtate; though if the leſſee confirm the land, to have and to hold to the leſſee and his heirs, this will enlarge the eſtate, and ſo of the reſt. Co. Litt. 299. Plowd. 40.

In every good confirmation, there may be a precedent rightful or wrongful eſtate in him to whom made, or he muſt have the poſſeſſion of the thing as a foundation on which the confirmation is to be eſtabliſhed; the confirmer muſt have ſuch an eſtate and property in the land, that he may thereby be enabled to confirm the eſtate of the confirmee; the precedent eſtate muſt continue till the confirmation come, ſo that the eſtate to be increaſed comes into it; and it is required that both theſe eſtates be lawful. Co. Litt. 296. 1 Rep. 146. Dyer. 109. 5 Rep. 15. If tenant for life make a leaſe for years to one perſon, and afterwards leaſe the land to another perſon for years; and he in reverſion confirms the laſt leaſe, and after that the firſt leaſe, this is not good; the ſecond leſſee hath an intereſt before by the confirmation of him in reverſion. But in a like caſe, confirmation of the firſt leaſe, after the ſecond was confirmed, has been held good; for the leaſe takes no intereſt by the confirmation, but only to make it durable and effectual. Moor. c. 180. 1 Inſt. 296. Plowd. 10. If a diſſeiſee confirm the land to the diſſeiſor but for one hour, one week, a year, or for life, &c. it is a good confirmation of the eſtate for ever; and if he confirm the eſtate of the diſſeiſor without any word of heirs, he hath a fee-ſimple; and if a diſſeiſee make a gift in tail, and the diſſeiſee doth confirm the eſtate of the donee, it ſhall enure to the whole eſtate. (Co. Litt. 291, 297, 299.) But where the eſtate is divided it is otherwiſe; and if there be an eſtate for life, the remainder over, there the confirmation may be of either of the eſtates; and if the leſſee of a diſſeiſor of a leaſe for 20 years, make a leaſe for 10 years, the diſſeiſee may confirm to one of them and not to the other. (1 Cro. 472. 5 Rep. 81.) The tenant in tail of land hath a reverſion in fee expectant; in this caſe, the confirmation of the eſtate tail will not extend to the reverſion: &c. (Co. Litt. 297, 298.) If leſſee for years, without impeachment for waſte, accept a confirmation of his eſtate for life, he hath by this loſt the privilege annexed to his eſtate for years. (8 Rep. 76.) Acceptance of rent in ſome caſes makes a confirmation of a leaſe. (2 Danv. 128, 129.) What a perſon may defeat by his entry, he may make good by his confirmation. (Co. Litt. 300.) But none can confirm, unleſs he hath a right at the time of the grant: he who hath but a right in reverſion cannot enlarge the eſtate of a leſſee. (2 Danv. 140, 141.) As confirmation is to bind the right of him who makes it, but not alter the nature of the eſtate to him to whom made, it ſhall not diſcharge a condition. (Poph. 51. 1 Rep. 147.) A confirmation will take away a condition annexed by law; and by confirmation, a condition after broken in a deed of feoffment is extinguiſhed. (1 Co. Rep. 146.) Confirmations may make a defeaſible eſtate good; but cannot work upon an eſtate that is void in law. (Co. Litt. 295.)

A confirmation of letters patent, which are void as they are againſt law, is a void confirmation. (1 Lil. Abr. 295.)

Grants and leaſes of biſhops, not warranted by the ſtat. 32 Hen. VIII. c. 28. muſt be confirmed by dean and chapter: and grants and leaſes of parſons, &c. by patron and ordinary. (1 Inſt. 247, 300, 301.) Biſhops may grant leaſes of their church-lands for 3 lives, or 21 years, having the qualities required by the fore-cited act, and concurrent leaſes for 21 years, with confirmation of dean and chapter. (See 1 Eliz. c. 4, 19.) If a prebend leaſes parcel of his prebendary, and the biſhop, who is patron, confirms it; this ſhall not bind the ſucceeding biſhop, without confirmation of dean and chapter, becauſe the patronage is parcel of the poſſeſſions of the biſhopric; but it ſhall bind the preſent biſhop, &c. (2 Danv. 139.) If a parſon grants a rent, the confirmation of the patron and biſhop is ſufficient without the dean and chapter, and ſhall be good againſt the ſucceeding biſhop. (Ibid. 140.) The dean of Wells may paſs his poſſeſſions, with the aſſent of the chapter, without any confirmation of the biſhop. (Ibid. 135.) See Lease.

To the grants of a "ſole corporation," as parſon, prebendary, vicar, and the like, the patron muſt give his conſent; becauſe ſuch a ſole corporation has not the abſolute fee; but a "corporation aggregate," as dean and chapter, maſter, fellows and ſcholars of a college, &c. or any ſole corporation that has the abſolute fee, as a biſhop with conſent of the dean and chapter, may by the common law make any grant of their poſſeſſions without their founder or patron. (1 Inſt. 300 *b.*)

A confirmation, as we have already obſerved, is in nature of a releaſe, and in ſome things of a greater force: and in this deed, it is good to recite the eſtate of the tenant, as alſo of him that is to confirm it, and to mention the conſideration; the words *ratify* and *confirm*, are commonly uſed; but the words *give, grant, demiſe*, &c. by implication of law, may enure as a confirmation. (1 Inſt. 295. Weſt. Symb. 1. p. 457.)

Confirmation, in *Rhetoric*, is, according to Quintilian, the third part, but according to Cicero, the fourth, of an oration, wherein the orator undertakes to prove, by laws, reaſons, authorities, and other arguments, the truth of the propoſitions advanced in his narration. Cicero. De Invent. lib. i. cap. 14. 24. Quint. Inſt. Orat. l. iii c. 9.

Confirmation is either *direct*, or *indirect*: the firſt confirms what the orator has to urge for ſtrengthening his own cauſe: the ſecond, properly called *confutation*, refels the oppoſite arguing of the adverſaries. The two parts together are ſometimes placed under the head or title of Contention.

As to the forms of reaſoning uſed by orators, for the purpoſe of confirmation, the Greek writers diſtribute them under four heads; *viz. Syllogiſm, Enthymeme, Induction*, and *Example.* (See each article, and alſo Argument and Argumentation.) Cicero reduces the rhetorical modes of reaſoning to two, which he calls *ratiocination* and *induction*, compriſing both ſyllogiſm and enthymeme under ratiocination, and example under induction; ſo that the difference lies in their manner of dividing them. As to the uſe of theſe modes of reaſoning, it is proper to vary them in a diſcourſe, and not to adhere too cloſely to the ſame form; for want of variety in this, as well as in other caſes, will ſoon create diſguſt. With regard to the diſpoſition of arguments, or the order of placing them, ſome adviſe to put the weaker, which cannot wholly be omitted, in the middle; and ſuch as are ſtronger, partly in the beginning, to gain the eſteem of the hearers, and render them more attentive; and partly at the end, becauſe what is laſt heard, is likely to be retained longeſt; and if there are but two arguments, to place the ſtronger firſt, and then the weaker; and after that to return again to the former, and inſiſt principally upon that. But this muſt be left to the prudence of the ſpeaker, and the nature of the ſubject. Nevertheleſs, it can never be proper to begin with the ſtrongeſt and ſo gradually deſcend to the weakeſt; for this would be a kind of anti-climax in reaſoning, which would be likely to deſtroy its effect. Arguments ought not to be crowded too cloſe upon one another; for then their force would be weakened, and the attention of the hearers would be ſo diſtracted, that they could not have ſufficient time duly to conſider them. Beſides, more arguments than are neceſſary ſhould not be uſed, becauſe the fewer they are, the more eaſily they are remembered. In this reſpect the obſervation of a great maſter of eloquence is very juſt, that "arguments ought rather to be weighed than numbered." Cic. de Orat. lib. ii. c. 76.

The confirmation is, as it were, the life and ſoul of the oration: in this the main ſtreſs of the argumentation lies. Whence Ariſtotle, properly enough, calls it πιστις, *fides.*

Confirmation of *Biſhops.* See Bishop.

Confirmation, in *Theology*, the ceremony of laying on of hands, for the conveyance of the Holy Ghoſt. When the apoſtles at Jeruſalem heard that many of the inhabitants of Samaria had embraced the Goſpel, and had been baptized, they ſent thither Peter and John, who laid their hands on theſe new converts, and prayed that they might receive the Holy Ghoſt, and the Holy Ghoſt deſcended upon them. (Acts, viii. 14, &c.) And when the men of Epheſus had been baptized, "Paul laid his hands upon them, and the Holy Ghoſt came upon them." (Acts, xix. 6.) And St. Paul, in his epiſtle to the Hebrews, (vi. 2.) mentions the doctrine of the laying on of hands immediately after the doctrine of baptiſm. Upon theſe authorities was founded the practice, which prevailed in the primitive church, of perſons receiving from the biſhop immediately after baptiſm, a ſolemn benediction, accompanied with impoſition of hands, unction upon the forehead with the holy chriſm (made of oil and balſam), the ſign of the Croſs, and a prayer for the deſcent of the Holy Ghoſt.

Among the ancients it was conferred immediately after baptiſm; and was eſteemed, in ſome meaſure, to be a part thereof: whence the fathers call it the *accompliſhment* of baptiſm. The ground of the practice was an opinion of the imperfection of baptiſm, which in their apprehenſion only prepared perſons for the reception of the graces of the Holy Spirit, which were actually conferred in confirmation. To this purpoſe Tertullian ſays, "when we come out of the water, we are anointed with a bleſſed ointment, according to that ancient rite by which men uſed to be anointed for the prieſt's office with oil out of a horn, ever ſince the time that Aaron was anointed by Moſes; ſo that Chriſt himſelf had his name from chriſm. (See Chrism.) Then we have the impoſition of hands on us, which calls down and invites the Holy Ghoſt." (Tertull. de Baptiſm. c. 7. King's Hiſt. of the Prim. Church, chap. v. p. 80, &c.) This ceremony was called confirmation, as it completed the admiſſion of the perſon into the Chriſtian church, and qualified him to partake of the Lord's Supper. It was not confined to adults, but infants alſo received confirmation as ſoon as they were baptized, and an opportunity offered of preſenting them to the biſhop.

Among the Greeks, and throughout the Eaſt, it ſtill accompanies baptiſm; but the Romaniſts make it a diſtinct independent ſacrament. The firſt expreſs inſtitution of this ceremony as a ſacrament occurs in the decree of pope Eugenius in 1439, in which he ſays, "the ſecond ſacrament is confirmation, the matter of which is chriſm bleſſed by the biſhop, and though the prieſt may give the other unction, the biſhop only can confer this." Peter Lombard, however, who lived in the 12th century, ſeems to have been the firſt who reckons ſeven ſacraments, and mentions confirmation as one of them. Although this ceremony was generally performed by biſhops, yet in ſome countries, and at ſome periods, it was performed by preſbyters; but in that caſe it was neceſſary that the chriſm ſhould have been previouſly conſecrated by the biſhop. St. Cyprian, and many of the fathers, ſpeak of it in ſuch terms as to imply, that the adminiſtration of it was confined to the biſhop alone. Jerome tells us, that in his time, confirmation was always performed in the Latin church by biſhops, as it had been in earlier times; and ſome have ſuppoſed that the cuſtom of receiving the impoſition of hands after baptiſm, to be performed by the biſhop alone, commenced in the time of this father; though he himſelf did not think that the Holy Spirit was given by the impoſition of the hands of the biſhop only: and he ſays, they are not to be lamented, who, being baptized by preſbyters or deacons in little villages, and caſtles, have died before they were viſited by biſhops. Hilary ſays, that in Egypt the preſbyters confirmed in the abſence of the biſhop: the ſame was alſo determined by the council of Orange; and this was the practice of the Greek church, which did not allow confirmation to be a ſacrament. From one of the canons of the council of Illiberis we learn, that, in the time of Cyprian and of Auguſtine, confirmation was performed by biſhops. Hence Fleury, and many of the moderns, lay it down as a diſtinguiſhing character between the offices of a prieſt or deacon, and that of a biſhop, that the former might baptize, but the latter alone might anoint and confirm; by virtue of their ſucceſſion to the apoſtles, to whom it originally belonged. But from ſome paſſages in St. Gregory, &c. others gather, that the prieſts, on occaſion, had likewiſe the power of confirming.

It has been alleged, that, as confirmation always ſucceeded baptiſm, and made a neceſſary part of it, and ſeveral of the primitive Chriſtians eſteemed both neceſſary to ſalvation, it muſt have been performed by preſbyters as well as by biſhops; becauſe the biſhop of a church might be abſent for a very conſiderable time, as was the caſe with Cyprian, or the ſee might be vacant: and as preſbyters baptized, it is reaſonable to conclude that they alſo confirmed. Lord King has ſhewn that confirmation and abſolution were the ſame thing; and that preſbyters, ſometimes with the biſhop, and ſometimes without the biſhop, did abſolve by impoſition of hands: and he has cited ſeveral ancient authorities in order to prove, that confirmation was frequently repeated with reſpect to the ſame perſons. (Hiſt. Prim. Church, p. 91, &c.)

It is certain, among the Greeks, the prieſt who baptizes, alſo confirms: which practice, Lucas Holſtenius ſhews, is of ſo old a ſtanding among them, that it is now generally looked on as belonging properly, and of right, to the prieſt: though ſome will have it to have been borrowed by them from the biſhops. Hence, ſome of the Latin divines acknowledge, that though the biſhop be the ordinary miniſter of confirmation, yet, that the prieſt, in his abſence, may alſo confer it, in quality of miniſter extraordinary.

The council of Rouen, held in 1072, decrees that confirmation muſt be conferred faſting, both on the ſide of the giver, and that of the receiver.

The ancients, and in this reſpect they are followed by the moderns, did not think this rite of confirmation ſo abſolutely neceſſary, that the want of it would exclude from the kingdom of heaven thoſe who had already been baptized; but they attributed to it ſo much importance, that they puniſhed the neglect of it with marks of diſgrace and public cenſure; and denied the privilege of eccleſiaſtical promotion and holy orders to ſuch perſons as had voluntarily and careleſsly omitted it.

"After this example of the primitive Chriſtians," ſays Dr. Tomline, the biſhop of Lincoln, "our church requires all who have been baptized to appear publicly in the congregation, and renew their baptiſmal vow according to the form preſcribed in our liturgy." The order of confirmation requires, "that none ſhall be confirmed but ſuch as can ſay the Creed, the Lord's Prayer, and the Ten Commandments, and can alſo anſwer to ſuch other queſtions as in the Short Catechiſm are contained, &c." The biſhop then queſtions them, whether they renew the ſolemn promiſe and vow that was made in their name at their baptiſm; ratifying and confirming the ſame in their own perſons, and acknowledging themſelves bound to believe and to do all thoſe things which their god-fathers and god-mothers then undertook for them? The biſhop in his general prayer declares before God that he hath vouchſafed to regenerate theſe his ſervants by water and the Holy Ghoſt, and hath given unto them forgiveneſs of all their ſins; and then laying his hand upon the head of every one ſeverally, offers a prayer for each individual. Moreover, in the collect which forms a part of this ſervice, he prays for thoſe that are confirmed, ſaying, "upon whom, (after the example of thy holy apoſtles), we have now laid our hands, to certify them (by this ſign) of thy favour and gracious goodneſs towards them." The order forbids any to be admitted to the holy communion, but thoſe who have been confirmed, or who are ready and deſirous to be confirmed. This order of confirmation does not mention the proper age of the perſon to be confirmed.

This ceremony, ſays the biſhop, "falls within the authority of the church, and may be conſidered as included in the general precept of doing all things "in order and unto edifying;" eſpecially ſince the now univerſal practice of infant baptiſm makes confirmation more neceſſary than it was in the primitive church, when chiefly adults were baptized. It ſeems highly reaſonable that they, who, at the time of their baptiſm, were incapable of making any engagement, ſhould, when they arrive at a proper age, ratify and confirm thoſe promiſes which were made in their name. And to give this ordinance the greater ſolemnity, it is performed only by the higher orders of the church, the archbiſhops and biſhops. Thus far our church receives confirmation, confining it to prayer and impoſition of hands, without the chriſm, or the ſign of the croſs, and believes it to be derived from the practice of the apoſtles. But as it is not a regular conſtitution of Chriſt and his apoſtles, like baptiſm and the Lord's ſupper, with a written command that it ſhould be continued in future ages, and a promiſe that it will be attended with inward grace, we reject it as a ſacrament. There is, indeed, not a ſingle precept upon the ſubject in the New Teſtament; nor is there any ſcriptural authority for the uſe of the chriſm or the ſign of the croſs; and Bingham thinks that the chriſm made no part of confirmation before the latter end of the ſecond century; though other writers attribute an earlier date to it. It muſt be admitted by all, that impoſition of hands was not peculiar to confirmation (ſee Matt. xix. 13. Mark, x. 16. Luke, iv. 40); and that no ſeparate efficacy is aſcribed to it diſtinct from the prayers which accompanied it; and prayer and impoſition of hands are not ſufficient to conſtitute a ſacrament: we, therefore, conſider confirmation as nothing more than a ſolemn manner of perſons' taking upon themſelves their baptiſmal vow; and as ſuch, it is a ceremony of high importance, calculated to impreſs youthful minds with a juſt ſenſe of the great obligations of the Chriſtian profeſſion, and to excite in them an earneſt endeavour "faithfully to obſerve ſuch things as they, by their own confeſſion, have aſſented unto." Elements of Chriſtian Theology, vol. ii. p. 416.

It has been urged, however, that this ceremony, with reſpect to the real importance and utility of it, was peculiar to the days of the apoſtles: and though it is retained among Proteſtants, it is doubted whether it be a neceſſary inſtrument of grace.

Some have thought it a remnant of the popiſh ſacrament of confirmation; and that there is no more authority for retaining this remnant, than for any thing that is omitted in the ceremony. It has been ſaid that the texts of ſcripture, repeatedly alleged in favour of this rite, have no weight. To this purpoſe it has been argued, that Peter's and John's going down to Samaria to pray, and to lay their hands on thoſe whom Philip had baptized, furniſhes no precedent, no direction, no inſtitution, nor command, for our biſhops, to do likewiſe. The end for which the apoſtles did it, as it is expreſsly ſaid (Acts, viii. 15. 17.), was, "that they might receive the Holy Ghoſt," *i. e.* its miraculous gifts, ſuch as propheſying, ſpeaking with tongues, &c. neceſſary for forming them into a church; in proof of which it is urged, that they were ſomething viſible and obvious to ſenſe; ſomething which excited the wonder and ambition of the wicked ſorcerer; for it is ſaid, "When Simon ſaw that through laying on of the apoſtles' hands the Holy Ghoſt was given, he offered them money." Beſides, Dr. Whitby has obſerved, that if they laid not their hands on *all* who were baptized, it makes nothing for confirmation; if they did, then Simon Magus alſo was confirmed, and received the Holy Ghoſt; which is not admiſſible. Our biſhops, it has been ſaid, diſclaim the powers exerciſed by the apoſtles. As for the open and ſolemn renewal of the baptiſmal covenant before God, which baptized perſons ought to make, when they come to years of diſcretion, this, it is ſaid, is done in the ſacrament of the Lord's ſupper, which Chriſt himſelf has appointed, and which is the *only* inſtitution his wiſdom has thought fit to appoint for this purpoſe. It has alſo been alleged that the ceremony of confirmation, however ſolemnly practiſed, has a tendency, the more from the ſolemnity of its adminiſtration, to cheriſh in men's minds a preſumptuous and falſe hope, and to delude them into wrong notions as to the ſafety of their ſtate, and as to the terms of acceptance and favour with God. What warrant, it has been aſked, has the biſhop to pronounce a man's "ſins all forgiven," and himſelf "regenerated by the Holy Ghoſt," upon no other grounds than his being able to repeat the Lord's Prayer, Creed, and Ten Commandments, and the anſwers of the Short Catechiſm? Can it be ſaid, that this is the Chriſtian doctrine concerning the terms of acceptance and favour with God? Are good vows and reſolutions, declared in the church, infallible or proper proofs of a regeneration by the Holy Ghoſt? Is a man's profeſſing that he repents, and promiſing that he will live a godly life, that actual repentance and amendment of life, which *alone* can enſure the divine pardon and favour? The multitudes, it is further ſaid, who come to be confirmed, are taught to conſider the biſhop, in the exerciſe of that part of his office, as an ambaſſador of Chriſt, a ſucceſſor of the apoſtles, and a ſpecial miniſter of God; and therefore, when they hear this ſacred perſon, ſolemnly declaring that they are fully juſtified, pardoned, and regenerated by the Holy Ghoſt, can they be blamed if they believe it, and reſt ſatiſfied with regard to the ſafety and happineſs of their ſtate? And as full remiſſion of ſins, and the favour of God are to be had on ſuch eaſy terms, is it matter of wonder, that thouſands ſhould eagerly flock from all quarters to accept it? Or that perſons of very vile and profligate characters ſhould too often thruſt themſelves in to partake of this benefit, and be ſeen receiving upon their knees epiſcopal abſolution, and ſolemn aſſurances of God's favour and peace?

It has been further argued by thoſe who object to the continued practice of this ceremony of confirmation in the Chriſtian church, that Tertullian is the moſt ancient author who has mentioned it, and that in his time, a great variety of ſuperſtitions, and ridiculous and fooliſh rites, had been introduced and actually ſubſiſted in the Chriſtian church. Confirmation was then always performed, as we have already mentioned, (not as it is with us, but) immediately after baptiſm. The expreſſion in our order of confirmation, by which the biſhop declares to God, "that he hath vouchſafed to regenerate theſe his ſervants by water and the Holy Ghoſt, and to give them the forgiveneſs of all their ſins," was probably taken from ſome ancient liturgy, and was ſuitable and well adapted to the practice of thoſe times, but is incongruous and unſuitable to ours. Then, as Dr. Cave obſerves, (Primitive Chriſtianity, pt. 1. p. 194, 208.) "although infants were undoubtedly taken into the church by baptiſm, yet the main body of the baptized were adult perſons; who, flocking over daily in great numbers to the faith of Chriſt, were received in at this door. Uſually they were for ſome conſiderable time catechized, and trained up in the principles of the Chriſtian faith; till having given teſtimony of their proficiency in knowledge, and of a ſober and regular converſation, they became candidates for baptiſm," or, as lord King ſays, (Inquiry into the Conſtitution, &c. pt. i. p. 102.) "the catechumens enjoyed not the privileges of the faithful, till they had, in a ſenſe, merited them, which was when, through a conſiderable time of trial, they had evidenced the ſincerity of their hearts, by the ſanctity and purity of their lives. And then, as Origen ſays, *we initiate them in our myſteries, when they have made a proficiency in holineſs, and according to the utmoſt of their power have reformed their converſation.* When they had changed their manners, and rectified their irregular carriage, then they were waſhed with the *water of baptiſm, and* NOT BEFORE. For, as Tertullian obſerves, we are not baptized *that we may ceaſe to ſin*; but *becauſe we have already ceaſed.*" In theſe circumſtances, it is ſaid, the biſhop or the preſbyter might uſe an expreſſion ſimilar to that already cited with propriety; but the caſe is different, ſay the objectors to the permanent uſe of this rite, with the multitudes who flock to modern confirmations. Pierce's Vindiciæ Frat. Diſſ. Towgood's Diſſent juſtified.

CONFISCATE, in *Law*, is applied to goods forfeited to the exchequer, or public treaſury.

The word is derived from *fiſcus, a hamper, panier*, or *baſket*, wherein the emperor's money uſed to be kept.

The title to goods, which are not claimed by any other, is given by law to the king. If a man, indicted for ſtealing the goods of another, in which caſe they become, in effect, the proper goods of him indicted, be aſked about them in court, and diſclaim them; he thereby loſes the goods, though he be afterwards acquitted of the theft; and the king ſhall have them as confiſcate; but otherwiſe, if he had not diſclaimed them. Thus alſo, when goods are found in the poſſeſſion of a felon, if he diſavows them and afterwards is attainted for other goods, and not for them, the goods which he diſavows are confiſcate to the king; but if he had been attainted for the ſame goods, they would have been ſaid to be "forfeited and not confiſcated." So if an appeal of robbery be brought, and the plaintiff leaves out ſome of his goods, he ſhall not be allowed to enlarge his appeal; and becauſe there is none to receive the goods ſo left out, the king ſhall have them as confiſcate, according to the rule, "Quod non capit chriſtus, capit fiſcus." Staundf. P. C. l. 3. c. 24. See Forfeiture.

CONFISCATION, a legal adjudication of goods or effects to the fiſc, or treaſury.

Thus, the bodies and effects of criminals, traitors, &c. and merchandizes that are contraband, prohibited, or brought aboard or aſhore, without paying the duties, when ſeized, are confiſcated.

It is an axiom in law, that he who confiſcates the body, confiſcates alſo the effects, to the profit of the king, or the lord of the fee, *i. e.* he who is condemned to loſe his life, muſt alſo loſe his goods; yet the widows of criminals do not loſe their dowries, nor their ſhare in the goods of the community, by the forfeiture of their huſbands. See Forfeiture.

CONFLAGRATION, a general burning of a city, or other conſiderable place. In which ſenſe, Nero is ſaid to have procured the Chriſtians to be accuſed of the conflagration of Rome, which was done by his own order.

But the word is more ordinarily reſtrained to that grand period, or cataſtrophe of our world, wherein the face of nature is expected to be changed by a deluge of fire, as it was anciently by that of water. The ancient Chaldæans, Pythagoreans, Platoniſts, Epicureans, Stoics, Celts, and Etrurians, appear to have had a notion of the conflagration; though whence they ſhould derive it, unleſs from the ſacred books, it is difficult to conceive; except perhaps, from the Phœnicians, who themſelves had it from the Jews.

The Celts, whoſe opinions reſembled thoſe of the eaſtern nations, held, that after the burning of the world, a new period of exiſtence would commence. The ancient Etrurians, or Tuſcans, alſo concurred with other weſtern and northern nations of Celtic origin, as well as with the Stoics, in aſſerting the entire renovation of nature after a long period, or great year, when a ſimilar ſucceſſion of events would again take place. The coſmogony of an ancient Etrurian, preſerved by Suidas, limits the duration of the univerſe to a period of 12,000 years, 6000 of which paſſed in the production of the viſible world, before the formation of man. The Stoics alſo maintained, that the world is liable to deſtruction from the prevalence of moiſture, or of drought; the former producing an univerſal inundation, and the latter an univerſal conflagration. Theſe, they ſay, ſucceed each other in nature, as regularly as winter and ſummer. When the univerſal inundation takes place, the whole ſurface of the earth is covered with water, and all animal life is deſtroyed; after which nature is renewed, and ſubſiſts as before, till the element of fire, prevailing in its turn, dries up all the moiſture, converts every ſubſtance into its own nature, and at laſt, by an univerſal conflagration, reduces the world to its priſtine ſtate. At this period all material forms are loſt in one chaotic maſs, all animated nature is reunited to the Deity, and nature again exiſts in its original form, as one whole, conſiſting of God and matter. From this chaotic ſtate, however, it again emerges, by the energy of the efficient principle; and gods and men, and all the forms of regulated nature are renewed, to be diſſolved and renewed in endleſs ſucceſſion. The doctrine of conflagration is a natural conſequence of the general ſyſtem of Stoiciſm. For, ſince, according to this ſyſtem, the whole proceſs of nature is carried on in a neceſſary ſeries of cauſes and effects, when that operative fire which at firſt, burſting from chaos, gave form to all things, and which has ſince pervaded and animated all nature, ſhall have conſumed its nutriment, that is, when the vapours, which are the food of the celeſtial fires, ſhall be exhauſted, a deficiency of moiſture muſt produce an univerſal conflagration. This grand revolution in nature is, after the doctrine of the Stoics, thus elegantly deſcribed by Ovid, (Metam. l. i. v. 256):

"Eſſe quoque in fatis reminiſcitur affore tempus
Quo mare, quo tellus, correptaque regio cœli
Ardeat, et mundi moles operoſa laboret:"

or, as Dryden has tranſlated the paſſage,

"Rememb'ring in the fates a time when fire
Should to the battlements of heaven aſpire,
When all his blazing worlds above ſhould burn,
And all th' inferior globe to cinders turn."

Seneca, ſpeaking of the ſame event, (Ad Murciam, c. ult.) ſays expreſsly, "Tempus advenerit quo ſidera ſideribus incurrent, et omni flagrante materia uno igne, quicquid nunc ex depoſito lucet, ardebit," &c. *i. e.* the time will come when the world will be conſumed, that it may be again renewed, when the powers of nature will be turned againſt herſelf; when ſtars will ruſh upon ſtars, and the whole material world, which now appears reſplendent with beauty and harmony, will be deſtroyed in one general conflagration. In this grand cataſtrophe of nature, all animated beings (excepting the univerſal intelligence), men, heroes, demons, and gods, ſhall periſh together. Seneca, the tragedian, who was of the ſame ſchool with the philoſopher, writes to the ſame purpoſe, (Herc. Oct. iii. 1112.)

"Cœli regia concidens
Ortus atque obitus trahet,
Atque omnes pariter deos
Perdet mors aliqua, et chaos."

i. e. "The mighty palace of the ſky,
In ruin fall'n is doom'd to lie,
And all the gods, its wreck beneath,
Shall ſink in chaos and in death."

During the courſe of this vaſt conflagration, the Stoics conceived that the world would expand, and in its chaotic ſtate continue to fill a much larger portion of infinite ſpace than it had required, or would again require, in a ſtate of orderly arrangement. After an interval of reſt, ſays Seneca, (Epiſt. 9. Qu. Nat. c. ult.) in which the Deity will be intent upon his own conceptions, the world will be entirely renewed; every animal will be reproduced; and a race of men, free from guilt, and born under happier ſtars, will repeople the earth. Degeneracy and corruption, will, however, again creep into the world; for it is only while the human race is young, that innocence remains upon the earth. The grand courſe of things, from the birth to the deſtruction of the world, which, according to the Stoics, is to be repeated in endleſs ſucceſſion, is accompliſhed within a certain period. This period, or fated round of nature, is probably what the ancients meant by the "Great Year."

From this brief account of the doctrine of the Stoics concerning the final conflagration, it evidently appears, that it differs in ſeveral eſſential particulars from the Chriſtian doctrine on this head. It is the work of fate, performed by natural and mechanical laws, and repeated eternally at certain periods, without any good reaſon, ſince with every revolution the ſame diſorders and vices return. Philo juſtly ridicules this dogma; remarking, that the Stoics make their deities act like children, who raiſe up piles of ſand only for the pleaſure of beating them down. Several of the Stoics themſelves were aware of the abſurdity of this ſyſtem, and rejected it; particularly Boethius, Poſidonius, Diogenes the Babylonian, and Pauætius. This general diſſolution the Stoics call εκπυρωσις, *ecpyroſis*. The Pythagoreans alſo maintained the dogma of conflagration. To this purpoſe Hippaſus, of Metapontum, taught that the univerſe is finite, is always changing, and undergoes a periodical conflagration. Philolaus, who flouriſhed in the time of Plato, maintained that the world is liable to deſtruction, both by fire and water.

Mention of the conflagration is alſo ſeveral times made in the books of the Sibyls, Sophocles, Hyſtaſpes, Lucan, &c.

Dr. Burnet, after F. Tachard, and others, relates, that the Siameſe believe, that the earth will at laſt be parched up with heat; the mountains melted down; and the earth's whole ſurface reduced to a level, and then conſumed with fire. And the Bramins of Siam do not only hold, that the world ſhall be deſtroyed by fire; but, alſo, that a new earth ſhall be made out of the cinders of the old.

The ſacred ſcriptures announce this event in a variety of paſſages; ſome of which, however, have been applied by Dr. Hammond, and others, to the deſtruction of Jeruſalem; but others are univerſally allowed to refer to this awful cataſtrophe. See 2 Pet. iii. 10—13, referred by Dr. Hammond to the deſtruction of Jeruſalem, and the diſſolution of the Jewiſh ſtate, but generally, and, with juſt reaſon, applied to the end of the world. (See Ray's Diſcourſes, p. 311, &c.) 2 Theſſ. i. 7, 8. Rev. vi. 12, 13, 14. Rev. x. 6. Rev. xxi. 1. Heb. xii. 26, 27. All theſe paſſages, and others, which more immediately relate to the time of this event, are applied by Dr. Hammond to the deſtruction of the city, temple, and polity of the Jews: and, indeed, he leaves only one place in the New Teſtament, as a proof of the general conflagration of the world; *viz.* 2 Pet. vii. 7. Other paſſages have been cited from the Old Teſtament that ſeem to indicate and foretel the diſſolution of the preſent globe: ſuch are Job. xiv. 12. Pſ. cii. 5, 6. Iſai. li. 6. Joel, ii. 31. Malachi, iv. 1. Deut. xxxii. 12. But it muſt be allowed that the prophetic books abound with figurative expreſſions, the preciſe object of which cannot be ſo ſatisfactorily aſcertained. The ancient fathers of the church, and Chriſtian writers, in ſucceſſive periods of its duration, have frequently referred to this event, and teſtified their belief of its advent. Some of the firſt Chriſtians apprehended it to be near at hand; and many of the ancients conceived that it would take place at the end of 6000 years. In this number we may claſs Juſtin Martyr, Irenæus, Lactantius, Euſtathius, &c.; but their opinion, with regard to the preciſe time of this event, is propoſed by them not as an undoubted truth, but only as a modeſt conjecture. It was the general opinion of the ancient Chriſtians, that this world ſhall not be annihilated or deſtroyed, but merely renewed and purified. To this purpoſe we might cite the teſtimonies of Euſebius, Cyril, Oecumenius, Jerome, and others.

Various are the ſentiments of authors on the ſubject of the conflagration; the cauſe whence it is to ariſe, and the effects it is to produce. Divines ordinarily account for it metaphyſically; and will have it take its riſe from a miracle, as a fire from heaven. Philoſophers contend for its being produced from natural cauſes; and will have it effected according to the laws of mechanics: ſome think an eruption of a central fire ſufficient for the purpoſe; and add, that this may be occaſioned ſeveral ways; *viz.* either by having its intenſity increaſed; which, again, may be effected either by being driven into leſs ſpace by the encroachments of the ſuperficial cold, or by an increaſe of the inflammability of the fuel whereon it is fed: or by having the reſiſtance of impriſoning earth weakened; which may happen, either from the diminution of its matter, by the conſumption of its central parts; or by weakening the coheſion of the conſtituent parts of the maſs, by the exceſs or the defect of moiſture.

Others look for the cauſe of the conflagration in the atmoſphere; and ſuppoſe, that ſome of the meteors there engendered in unuſual quantities, and exploded with unuſual vehemence, from the concurrency of various circumſtances, may be made to effect it, without ſeeking any further.

The aſtrologers account for it from a conjunction of all the planets in the ſign Cancer; as the deluge, ſay they, was occaſioned by their conjunction in Capricorn. This was an opinion adopted by the ancient Chaldæans.

Laſtly: others have recourſe to a ſtill more effectual and flaming machine; and conclude the world is to undergo its conflagration from the near approach of a comet, in its return from the ſun. Thoſe wandering bodies do indeed ſeem to menace us a little; being able, both by their tranſverſe motion acroſs the earth's way, by the hugeneſs of their ſize, and the intenſe fire wherewith they glow in their receſs from the perihelion, to produce the moſt ſignal changes and revolutions in the ſyſtem of things.

Mr. Whiſton has ſhewn, that they are extremely well fitted to produce the phenomena of the deluge; and has gone a good way towards proving, that the comet of 1680, was the very body to which that event was owing; as being then in its approach towards the ſun, and its atmoſphere crowded with the watery vapours, which it had gathered in thoſe inconceivably cold regions, into which it had fled off in its aphelion.

This ſame comet, ſir Iſaac Newton has calculated, when in its perihelion, December the 8th, was heated, by the vicinity of the ſun, to a degree two thouſand times more hot than red-hot iron: he ſhews, likewiſe, that it would ſcarce be cool again in fifty thouſand years.

This ſame comet, Dr. Halley obſerved November the 11th, was not above a ſemidiameter of the earth from the earth's way: ſo that had the earth, at that time, been in that part of its orbit, ſomething very extraordinary might have been apprehended; but whether in the way of fire, or water, may, perhaps, to ſome, leave room to doubt. But it is ſcarcely conceivable, that the comet ſhould bring any vehement degree of heat, out of thoſe regions it comes from, whatever heat it might carry thither. See COMET. See on the ſubject of this article *Theory of the* EARTH.

CONFLANS, in *Geography*, a ſmall town of France, in the department of Mont-blanc, and chief place of a canton in the diſtrict of Moutiers, 18 miles N.E. from Moutiers. The place contains 1313, and the canton 5512 inhabitants: the territory includes 182½ kiliometres and 10 communes.—Alſo, a ſmall town of France, in the department of Moſelle, and chief place of a canton in the diſtrict of Briey, ſituated at the confluence of the Iron and Orn, 15 miles E. from Metz. This place contains but 347, and the canton 7145 inhabitants, and 31 communes, upon a territorial extent of 240 kiliometres.—Alſo, a town of France, in the department of the Upper Saone, in the diſtrict of Lure; 4 leagues N. of Veſoul, and 2½ W. of Luxeuil.—Alſo, a town of Savoy, near the conflux of the Iſere and Doron; 18 miles E. of Chambery.

CONFLANS, or *Conflaut*, was, before the revolution, the name of a valley of France, in Rouſillon, ſurrounded by the Pyrenées, and watered by the river Tet. Villefranche ſur le Tet was its capital.

Conflans *St. Honorine*, a town of France, in the department of the Seine and Oiſe; 5 leagues S.W. of Paris.

CONFLICT. See Combat.

CONFLUENCE, Conflux, the place where two rivers join, and mix their waters.

CONFLUENT, in *Medicine*, literally *flowing together*, is a term applied to cutaneous eruptions, which, though conſiſting, on their firſt appearance, of ſeparate and diſtinct ſpots, form themſelves ſubſequently into extenſive patches, by the ſpreading of the individual ſpots, which coaleſce with each other. This epithet is moſt frequently applied to the ſmall pox, which, when confluent, becomes a very formidable and fatal diſeaſe, and requires a treatment in its latter ſtages, different from that which is beneficial in the mild form of the diſeaſe, when the puſtules are few and diſtinct. See Small-Pox.

CONFLUENTA, in *Ancient Geography*, a town of Spain, belonging to the Vaccæans, S.E. of Pallentia.

CONFLUENTES. See Coblentz.

CONFOLENS, in *Geography*, a town of France, in the department of Charente, and chief place of a diſtrict, ſituated on the river Vienne, 30 miles N.W. from Limoges, and 36 N.E. from Angoulême. It has a ſub-prefect, a court of juſtice, and a regiſter-office. It is divided into north and ſouth, and has a population of 2025 inhabitants. Its northern canton compriſes 7391, and the ſouthern 11,385 inhabitants, diſtributed in 18 communes, upon a territorial extent of 342½ kiliometres. The diſtrict reckons 58,503 inhabitants and 70 communes, on a territorial extent of 1432½ kiliometres. Its ſoil in general is a barren heath, except on the banks of the Vienne, which afford ſome good corn land and excellent paſtures. Corn and cattle are the principal articles of commerce. N. lat. 46° 2′. E. long. 0° 34′.

CONFORMATION, the particular texture and conſiſtence of the parts of any body, and their diſpoſition to make a whole.

We ſay, light of different colours is reflected from bodies, according to their different conformation; in oppoſition to the Carteſians, who pretend, that reflected light becomes of different colours, according to the different conformation of the bodies that reflect it. The conformation of the members of an embryo is not perfect enough to allow of diſſection.

CONFORMITY, in the *Schools*, is the congruency, or relation of agreement between one thing and another: as between the meaſure, and the thing meaſured: the object, and the underſtanding; the thing, and the conception; the thing, and the diviſion thereof, &c.

Conformity, *Non.* See Non-conformity.

Conformity, *Occaſional.* See Occasional Conformity.

CONFRERES, from *con*, and *frere*, *brother*; denote brethren in a religious houſe, or the fellows of one and the ſame ſociety. 32 Hen. VIII. c. 24.

CONFRONTATION, the act of bringing two perſons, in preſence of each other, to diſcover the truth of ſome fact, which they relate differently.

The word is chiefly uſed in criminal matters; where the witneſſes are confronted with the accuſed; the accuſed with one another, or the witneſſes with one another.

CONFUCIUS, or Kong-fu-tse, in *Biography*, the moſt celebrated ancient philoſopher of China, deſcended from the imperial family of the dynaſty of Shang, was born in the reign of the emperor Lu, about four centuries and a half before Chriſt. He was accordingly a contemporary with Pythagoras, and flouriſhed at a period prior to that in which Socrates roſe to celebrity. At fifteen years of age, he engaged in the ſtudy of the ancient learning of his country; and, before he had arrived at the years of manhood, he had made aſtoniſhing proficiency in the doctrines attributed to the legiſlators Yao and Chun, which the Chineſe conſider as the ſource of all their ſcience and morality. The reputation which Confucius acquired, and the uncommon wiſdom which he diſcovered, were the means of advancing him, while he was yet but a youth, to the office of miniſter of ſtate. The duties of this, and of other poſts aſſigned to him, he performed with honour to himſelf, and ſignal benefit to the kingdom. The rank which he held in public life, enabled him to form an accurate judgment of the ſtate of morals among his countrymen. He deviſed a plan for a general reformation, which he endeavoured to carry into execution, as well by inculcating a ſtrict and pure morality, as by uſing the influence of his authority in recommending it. His efforts were crowned with ſo much ſucceſs, that the whole nation became, at firſt, a pattern of order, decorum, and ſtrict juſtice. This reformation was not, however, permanent; the buſineſs of the ſtate was abandoned to men of licentious habits, and in a ſhort time an univerſal effeminacy and diſſoluteneſs of manners prevailed. Confucius exerted all his powers to ſtem the torrent of vice; and when he found that his endeavours were fruitleſs, he reſolved to quit his ſtation and country, and ſeek an aſylum in ſome other kingdom where his efforts in the cauſe of virtue might be more availing. He, at length, devoted himſelf to the taſk of private inſtruction in philoſophy and morality. His great celebrity, and his perſonal virtues, ſoon procured him many ſcholars; and he is ſaid to have had ſeveral thouſand diſciples to whom he taught morals, the art of reaſoning, and the principles of policy. From theſe he ſelected ſeventy-two, who were diſtinguiſhed from the others on account of their ſuperior attainments. Theſe were divided into claſſes, deſtined for different purpoſes. The buſineſs of the firſt claſs was the ſtudy of morals; of the ſecond, that of reaſoning and eloquence; of the third, that of the rules of good government; and the immediate province of the fourth was ſomething ſimilar to our public preaching. The exertions of Confucius in the cauſe of virtue, were too great for the frame of body with which he was endued; his natural ſtrength became impaired, and his mental powers failed. During his laſt ſickneſs, he declared that his heart was overpowered with grief, on beholding the diſorders which prevailed in the empire, and which he had in vain endeavoured to ſuppreſs: "The kings," ſaid he, "will not follow my maxims; I am no longer uſeful on earth; it is, therefore, time that I quit it." This exclamation was followed by a lethargy from which he never recovered. He died in his ſeventy-third year. B. C. about 479, (Blair.) By his ſage counſels, his moral doctrine, and his exemplary conduct, he obtained an immortal name as a reformer of his country After his death, his name was held in the higheſt veneration, and his doctrine is ſtill regarded among the Chineſe, as the baſis of all moral and political wiſdom. His natural temper was excellent, and his conduct irreproachable and exemplary. He was particularly praiſed for his humility, ſincerity, temperance, diſintereſtedneſs, and contempt of riches.

Confucius ſeemed deſigned by heaven to reform, both by his doctrines and example, the corruptions which prevailed, as well in the civil, as in the religious eſtabliſhments of China. He condemned the idolatry which he found exiſting among his countrymen, and endeavoured to introduce a purer form of religion. He did not attempt to dive into the impenetrable ſecrets of nature, nor bewilder himſelf in abſtruſe reſearches on the eſſence of a firſt cauſe, the origin of good and evil, and other ſubjects which ſeem beyond the limits of the human mind. He maintained that the Deity was the moſt pure and perfect principle, and fountain of all things; that he is independent and almighty, and watches over the government of the univerſe, ſo that no event can happen but by his command; that our moſt ſecret thoughts are open to his view; that he is holy without partiality, and of ſuch boundleſs goodneſs and juſtice, that he cannot poſſibly permit virtue to go unrewarded, or vice unpuniſhed.

So high is the reſpect paid to the memory of this great man, even in the preſent day, that his deſcendants enjoy, by inheritance, the title and office of mandarins, and are allowed the privilege in common with the princes of the blood, of exemption from the payment of all taxes to the emperor. The works which Confucius compoſed for the uſe of his diſciples, and the preſervation of his philoſophy, are looked upon by the Chineſe as of the firſt authority, next to the claſſical books, ſtyled by way of eminence, "the Five Volumes;" and to theſe, indeed, he declares himſelf indebted for the information and wiſdom which his own are calculated to convey. Moreri. Hiſt. Univer. D'Anquetil. Enfield's Hiſt. of Philoſophy.

CONFUSED *Notion* and *Viſion*. See the ſubſtantives.

CONFUSION, in a general ſenſe, is oppoſed to order; in a perturbation whereof, confuſion conſiſts: *e. gr.* when things prior in nature do not precede; or poſterior do not follow, &c.

In a logical ſenſe, confuſion is oppoſed to diſtinctneſs, or perſpicuity; and may happen, either in words, as when miſconſtrued or miſapplied; or in ideas, as when the idea of any thing preſents ſomething along with it, which does not properly belong to that thing.

In a phyſical ſenſe, confuſion is a ſort of union, or mixture by mere contiguity. Such is that between fluids of contrary natures; as oil and vinegar, &c.

CONFUSION, *property by*, in *Law*, denotes the intermixture of the goods of two perſons in ſuch a manner, that their reſpective portions cannot be aſcertained. If this be by conſent, they have a common intereſt, both by the Engliſh and civil law, in proportion to their ſhares. But, if one wilfully intermixes his money, corn, or hay, with that of another perſon, without his approbation or knowledge, or caſts gold in like manner into another's pot or crucible, the civil law, though it gives the ſole property of the whole to him who has not interfered in the mixture, yet allows a ſatisfaction to the other for what he has ſo improvidently loſt. (Inſt. 2. 1, 28). But our law, to guard againſt fraud, gives the entire property, without any account, to him, whoſe original dominion is invaded, and endeavoured to be rendered uncertain, without his own conſent. Poph. 38. 2 Bulſtr. 325. 1 Hal. P. C. 513. 2 Vern. 516. Bl. Comm. ii. 405.

CONFUSION *of tongues*, in the *Hiſtory of the World*, is a memorable event, which happened in the one hundred and firſt year, according to the Hebrew chronology, after the flood, B. C. 2247, at the overthrow of Babel; and which was providentially brought about, in order to facilitate the diſperſion of mankind, and the population of the earth. Until this period, there had been one common language, which formed a bond of union, that prevented the ſeparation of mankind into diſtinct nations; and ſome have ſuppoſed, that the tower of Babel was erected as a kind of fortreſs, by which the people intended to defend themſelves againſt that ſeparation, which Noah had projected.

There has been a conſiderable difference of opinion, as to the nature of this confuſion, and the manner in which it was effected. Some learned men, prepoſſeſſed with the notion that all the different idioms now in the world did at firſt ariſe from one original language, to which they may be reduced, and that the variety among them is no more than muſt naturally have happened in a long courſe of time by the mere ſeparation of the builders of Babel, have maintained, that there were no new languages formed at the confuſion; but that this event was accompliſhed by creating a miſunderſtanding and variance among the builders, without any immediate influence on their language. But this opinion, advanced by Le Clerc, &c. ſeems to be directly contrary to the obvious meaning of the word שפה, *ſhapha, lip*, uſed by the ſacred hiſtorian; which, in other parts of ſcripture, ſignifies *ſpeech*. (See Pſ. lxxxi. 5. Iſ. xxviii. 11. xxxiii. 19. Ezek. iii. 5.) It has been juſtly remarked, that unanimity of ſentiment, and identity of language, are particularly diſtinguiſhed from each other in the hiſtory; "the people is one, and they have all one language." (Gen. xi. 6.) It has been alſo ſuggeſted, that if diſagreement in opinion and counſel were the whole that was intended, it would have had a contrary effect; they would not have deſiſted from their project, but ſtrenuouſly have maintained their reſpective opinions, till the greater number of them had compelled the minority either to fly or to ſubmit. Others have imagined, that this was brought about by a temporary confuſion of their ſpeech, or rather of their apprehenſions, cauſing them, whilſt they continued together and ſpoke the ſame language, to underſtand the words differently: Scaliger is of this opinion. Others again account for this event, by the privation of all language, and by ſuppoſing that mankind were under a neceſſity of aſſociating together, and of impoſing new names on things by common conſent. Another opinion aſcribes the confuſion to ſuch an indiſtinct remembrance of the original language which they ſpoke before, as made them ſpeak it very differently; ſo that by the various inflections, terminations, and pronunciations of divers dialects, they could no more underſtand one another, than they who underſtand Latin can underſtand thoſe who ſpeak French, Italian, or Spaniſh, though all theſe languages ariſe out of it. This opinion is adopted by Cauſabon, and by biſhop Patrick in his Commentary in loc. and is certainly much more probable than either of the former: and Mr. Shuckford maintains, that the confuſion aroſe from ſmall beginnings, by the invention of new words in either of the three families of Shem, Ham, and Japhet, which might contribute to ſeparate them from one another; and that in each family new differences of ſpeech might gradually ariſe, ſo that each of theſe families went on to divide and ſubdivide among themſelves. Others, again, as Mr. Joſ. Mede and Dr. Wotton, &c. not ſatiſfied with either of the foregoing methods of accounting for the diverſity of languages among mankind, have recourſe to an extraordinary interpoſition of divine power, by which new languages were framed and communicated to different families by a ſupernatural infuſion or inſpiration; which languages have been the roots and originals from which the ſeveral dialects that are, or have been, or will be ſpoken, as long as this earth ſhall laſt, have ariſen, and to which they may with eaſe be reduced. This opinion is adopted and vindicated by Dr. Hartley, in his "Obſervations on Man," p. 179, who ſays, that it ſeems impoſſible to explain how the human languages ſhould ariſe from one ſtock. Upon the whole, we may obſerve, that there evidently ſeems to have been ſomething miraculous in the tranſaction; and if it be ſuppoſed that nothing more was meant than a confuſion of deſigns, counſels, and opinions; ſo that they could not agree together in the execution of their ſcheme (which, as we have ſhewn, is not very probable); this would be ſufficient to anſwer the purpoſe of Divine Providence, which was to prevent the children of Noah from preſerving their union in one body, and to ſpread them over the face of the earth, that it might be peopled and cultivated. If the confuſion of tongues was an actual change of languages, it was probably accompliſhed by degrees; nor does it appear to be ſo fundamental and radical an alteration as ſome have imagined. In proof of this, we may allege the free intercourſe which ſubſiſted in early times between perſons of different ages and countries; the uniformity of the Eaſtern languages, which plainly ſhews that they have one common radix; and the manifeſt derivation of the Greek and Latin from the ſame ſource.

As to the number of languages thus introduced, many opinions have been adopted. If there were no more than there were nations or heads of nations, then the number would be ſeven for Japhet, four for Ham, and five for Shem; but if there were as many as there were families, which is the more probable opinion, their number cannot be certainly aſſigned. However, the Hebrews fancy they were ſeventy, becauſe the deſcendants from the ſons of Noah, enumerated Geneſis x., were juſt ſo many. Allowing then the languages of the chief families to have been fundamentally different from each other, the ſub-languages and dialects within each branch would probably have had a mutual affinity, greater or leſs, as they ſettled nearer or farther from each other. But whichſoever of theſe hypotheſes is adopted, the primary object of the confuſion at Babel was the ſeparation and diſperſion of mankind. Cleric. Com. in Gen. x. i. Scaliger Exerc. in Cardan. § i. Caſaubon. Diatrib. de Ling. Heb. Mede's Works, vol. i. p. 276. Wotton's Diſc. and Brett's Eſſ. on the Confuſion of Languages. Univerſ. Hiſt. vol. i. part i. chap. 2. § 5. Shuckf. Conn. vol. i. p. 146.

The ingenious and learned Dr. Bryant has, in the third volume of his "Analyſis of Ancient Mythology," advanced a new and ſingular hypotheſis, both with reſpect to the confuſion of tongues and the diſperſion. He ſuppoſes that the confuſion of language was local and partial, and limited to Babel only. By כל־הארץ, Gen. xi. 1 and 8, which our tranſlators render the *whole earth*, he underſtands *every region:* and by the ſame words in ver. 9, the *whole region*, or province. This confuſion was occaſioned, as he ſuppoſes, by a labial failure; ſo that the people could not articulate. Thus their ſpeech was confounded, but not altered; for as ſoon as they ſeparated, they recovered their true tenor of pronunciation, and the language of the earth continued for ſome ages nearly the ſame. The interviews between the Hebrews and other nations, recorded in Scripture, were conducted without an interpreter; and he farther obſerves, that the various languages which ſubſiſt at this day retain ſufficient relation to ſhew, that they were once dialects from the ſame matrix, and that their variety was the effect of time. See DISPERSION.

CONFUTATION, in *Rhetoric*, &c. a part of an oration, wherein the orator ſeconds his own arguments, and ſtrengthens his cauſe, by refelling and deſtroying the oppoſite arguments of the antagoniſt. This is done by denying what is apparently falſe, by detecting ſome flaw in the reaſoning of the adverſe party, by granting their argument, and ſhewing its invalidity, or retorting it upon the adverſary.

Confutation makes a branch of what we call *confirmation.* The confirmation and confutation are ſometimes called *contention.*

Rhetoricians generally place confutation after confirmation, which ſeems agreeable to the natural method of thinking on any ſubject. For perſons firſt endeavour to find out ſuch arguments as are proper to maintain that ſide of a queſtion which they eſpouſe, before they conſider what objections may be offered againſt it: although in ſpeaking it may be neceſſary to vary the order, according to the nature of the diſcourſe. The method preſcribed by Quintilian (Inſt. Orat. l. v. c. 13.) is this, that, "if we bring a charge, we ſhould firſt prove it, and then anſwer objections; but if we ſtand upon the defence, we ought to begin with confutation." The forms of reaſoning are the ſame here as thoſe that occur under *confirmation.* But it is of importance to know the different modes of confutation practiſed by orators, which is often the more difficult taſk; becauſe he, who is to prove a thing, comes uſually prepared; but he, who is to confute it, is frequently left to a ſudden anſwer. Hence Quintilian ſays, that, in judicial caſes, "it is as much eaſier to accuſe than to defend; as it is to make a wound than to heal it." In all diſputes it is of the greateſt conſequence to obſerve, where the ſtreſs of the controverſy lies; and in confutation, what the adverſary has advanced ought carefully to be conſidered, and in what manner he has expreſſed himſelf. Thoſe things, which relate to the merits of the cauſe, may be confuted either by contradicting them, or by ſhewing ſome miſtake in the reaſoning, or their invalidity when granted. There are various ways in which things may be contradicted; what is apparently falſe may be expreſsly denied; and things which the adverſary cannot prove may be likewiſe denied. A thing may be alſo contradicted by ſhewing that the adverſary himſelf maintained the contrary. When you can fix contradictions on an adverſary, you effectually ſilence him; for this is ſtabbing him with his own weapon. Sometimes a thing is not in expreſs terms denied, but repreſented to be utterly incredible; and this method expoſes the adverſary more than a bare denial. There is, likewiſe, an ironical way of contradicting a thing, by retorting that and other things of the like nature upon the adverſe party. A ſecond mode of confutation is by obſerving ſome flaw in the reaſoning of the adverſe party. The laſt method of confutation is, when the orator does in ſome ſenſe grant the adverſary his argument, and at the ſame time ſhews its invalidity. This may be done in a variety of ways, according to the different nature of the ſubject. Sometimes he allows that what was ſaid may be true, but pleads, that what he contends for is neceſſary. At other times the orator pleads, that although the contrary opinion may ſeem to be attended with advantage, yet that his own is more juſt and honourable. Another way of confutation is by retorting upon the adverſary his own argument. The orator takes this advantage, when an argument proves too much, that is, more than the perſon deſigned it for, who made uſe of it. See INVERSION. Sometimes orators in confutation raiſe ſuch objections themſelves to what they have ſaid, as they imagine may be made by others; which they afterwards anſwer the better to induce their hearers to think, that nothing conſiderable can be offered againſt what they have advanced, but what will admit of an eaſy reply. See PROLEPSIS. See the ſeveral modes of confutation above recited illuſtrated by appoſite citations from Cicero's Orations in Ward's Oratory, vol. i. lect. 17.

As to the order and diſpoſition of the arguments, proper to be uſed in confutation; whether to follow the adverſe party, or alter his method, and range them in a different manner, as likewiſe whether to attack the weakeſt or ſtrongeſt arguments firſt; theſe things muſt be left to the diſcrétion of the ſpeakers.

CONG, in *Geography*, a village of the county of Mayo, Ireland, ſituated in the neck of land between the Loughs, Maſk, and Corrib. Large caverns and ſubterraneous waters are frequent in the neighbourhood; eſpecially at the back of the village, a very broad river ruſhes at once from beneath a gently ſloping bank, and after a rapid courſe of about a mile loſes itſelf in Lough Corrib. It is ſuppoſed to be the outlet of a ſubterraneous channel, through which the ſuperfluous waters of Loughs Maſk and Carrah are diſcharged into Corrib. Cong is about 108 miles weſt from Dublin, and 20 ſouth from Caſtlebar.

Cong, a town of China of the third rank, in the province of Honan; 15 miles ſouth of Hoai-king.—Alſo, a town of China of the third rank, in the province of Se-tchuen; 25 miles ſouth of Soui-tcheou.

CONGA, a town of Perſia, in the province of Irak-Agemi: 100 miles N. W. of Iſpahan.

CONGAREE, a conſiderable river of America, in the ſtate of S. Carolina, formed by the confluence of Saluda and Broad rivers. The union of the waters of Congaree and Wateree forms the Santee.

CONGAUTATA, in *Ancient Geography*, a ſtation on the line of Severus's wall in Britain, mentioned in the Notitia Imperii, and ſuppoſed to be at Stanwix.

CONGE, Apophyge, Gr. *Scapus*, Lat. in *Architecture*. The extremities of the ſhaft of a column when they are worked circularly to unite gradually with the filets of the baſe and capital are thus named.

Conge, in the *French Law*, a licence, or permiſſion, granted by a ſuperior to an inferior, which gives him a diſpenſation from ſome duty to which he was before obliged. The word is French: Menage derives it from the Latin *commiatus*, uſed for *commeatus*, and *commeare*, often ſeen among ancient writers: the Italians ſay, *congedo*.

A monk cannot go out of his convent, without the conge of his ſuperiors.

Conge *d'accorder*, i. e. *leave to accord*, or *agree*, is uſed in the ſtatute of fines, anno 18 Edw. I. to the following purpoſe. "When the original is delivered, in preſence of the parties before juſtices, a pleader ſhall ſay this: ſir, juſtice, *conge d'accorder*; and the juſtice ſhall ſay to him, What ſaith ſir R. and ſhall name one of the parties, &c."

Conge *d'elire*, is the king's permiſſion royal to a dean and chapter, in time of a vacancy, to chooſe a biſhop. See Bishop, Canon, and Collation.

Gwyn obſerves, that the king of England, as ſovereign patron of all biſhoprics and other benefices, had anciently the free appointment of all eccleſiaſtical dignities; inveſting, firſt, *per baculum & annulum*; and afterwards by letters patent: but that, in proceſs of time, he made the election over to others, under certain forms and conditions; as, that they ſhould at every vacancy, before they choſe, demand of the king *congé d'elire*, *i. e.* leave to proceed to election; and after election to crave his royal aſſent, &c. He adds, that king John was the firſt who granted this; which was afterwards confirmed by ſtat. Weſtm. 3 Edw. I. cap. 1. and again in the Articuli Cleri, 25 Edw. III. cap. 1.

Conge, in *Military Language*, leave of abſence granted to an officer or ſoldier from his corps, from the army or altogether from the ſervice. The old ſervice of France admitted of two kinds; namely, the *congé limité*, a ſpecific or limited leave, and the *congé abſolu*, or an abſolute diſcharge. In the latter caſe there was delivered to the ſoldier a *cartouche*, with all the ſignatures on it neceſſary for the good order and regularity of the ſervice, and for the tranquility of the perſon, who obtained it. The *congé abſolu* was always ſuſpended in time of war.

CONGEABLE, from the French *congé* (i. e. *leave*, *licence*, or *permiſſion*), ſignifies as much as lawful, or lawfully done, or done with leave or permiſſion; as, *then entry of the diſſeiſee is* congeable.

CONGELATION (from the Latin *congelo*), means the tranſition of a liquid into a ſolid ſtate, in conſequence of the abſtraction of heat; thus metals, butter, oils, water, &c. are ſaid to *congeal*, when, from a fluid ſtate, they paſs into that of a ſolid.

Congelation and freezing mean, in fact, the ſame effect; yet the term congelation is indiſcriminately applied to all the above-mentioned tranſitions; whereas the word freezing is more commonly uſed for denoting the congelation of water, of vinegar, of brandy, of mercury, and in ſhort of all thoſe ſubſtances which, in order to become ſolid, muſt be cooled below 32° of Fahrenheit's thermometer. We ſhall, however, in this work, divide the ſubject of congelation under the two above-mentioned denominations; ſtating, under the preſent article, whatever relates to natural congelation, and under the article Freezing, whatever relates to the artificial methods of freezing.

Another important proceſs, much connected with congelation, has been improperly ſeparated from it. And this is *cryſtallization*, or the arrangement of certain ſubſtances into regular figures, in their tranſitions from the fluid into the ſolid ſtate; but water and ſeveral other bodies likewiſe cryſtallize in congealing, which ſhews that the two proceſſes can hardly be ſeparated; and this is rendered ſtill more evident by a due conſideration of other phenomena that accompany both proceſſes. Allowing therefore that cryſtallization and congelation are eſſentially of the ſame claſs, a ſlight diſcrimination may be formed by applying the term cryſtallization to the formation of thoſe regular forms or cryſtals, which are of a compound nature, and which, when once formed, generally require a much greater degree of heat for their liquefaction, than that in which they were formed.

By far the greater number of liquids we are acquainted with, have been found capable of congelation in a proper temperature; and on the other hand moſt of thoſe ſolids which are ſuch in the uſual temperature of the atmoſphere may be rendered fluid by the application of certain appropriate degrees of heat; hence we are led by analogy to ſuppoſe, that every fluid might be congealed, if it were poſſible to cool it ſufficiently; or that fluidity is the effect or conſequence of heat. Every particular kind of ſubſtance requires a different degree of temperature for its congelation; hence it appears why certain ſubſtances remain always fluid, whilſt others remain always ſolid, in the ordinary temperature of the atmoſphere, and why certain other ſubſtances are ſometimes fluid, and at other times ſolid, according to the viciſſitudes of the weather, the difference of ſeaſons, and the variety of climates.

Heat, or ſenſible caloric, continually tends to paſs from thoſe bodies which have more of it than their proper ſhare, to thoſe contiguous bodies which have leſs of it than their proper ſhare; hence, when a body is placed amongſt other bodies of a lower temperature, its heat gradually paſſes to thoſe other bodies, until the whole acquires the ſame temperature; and this tranſition proceeds regularly, excepting, however, when the body is in the act of aſſuming the ſolid ſtate; for at that moment a ſudden extrication of heat is obſervable. Place a thermometer in a glaſs full of water, and place the glaſs in a freezing mixture of broken ice, and common ſalt, the thermometer will be found to deſcend gradually as low as 30, or 28 degrees of Fahrenheit's thermometer, and ſometimes even much lower, whilſt the water remains fluid; but, at laſt, the water begins to freeze, and at that very moment the thermometer riſes ſuddenly to 32°, and it remains at that point until the whole of the water is congealed. If then the application of the freezing mixture be continued, the thermometer will ſink gradually ſeveral degrees below 32°, according to the activity of the freezing mixture. We may, Dr. Black obſerves, eaſily ſatisfy ourſelves, that the water, while congealing, is continually imparting heat to the ſurrounding air; for, if we ſuſpend a delicate thermometer immediately above the water, we ſhall find the inſtrument affected by an aſcending ſtream of air, leſs cold than the air around.

Not only pure water, but all aqueous fluids, may be cooled down 7, or 8, or 10 degrees without freezing; but if in that ſtate they be affected with a tremulous motion, or if they be touched with a ſlender piece of ice, they will inſtantly ſhoot into beautiful ſpiculæ, the thermometer in it riſing at the ſame time. This ſtriking phenomenon of the ſudden riſing of the thermometer at the moment of congelation, which has alſo been remarked in wax, ſpermaceti, and other ſubſtances, has not yet been fully or ſatisfactorily explained, It is true that ice has not ſo great a capacity for containing heat as water has; (ſee the capacities of bodies under the article Caloric and Heat); but why ſhould water ſo reluctantly part with that ſuperfluous quantity of heat as to ſuffer itſelf ſometimes to be cooled ſeveral degrees below 32, before it will aſſume the ſolid form?

Since water, when it has once begun to congeal, remains at the apparent temperature of 32° until the whole of it is congealed; and ſince water cannot remain congealed in a temperature higher than 32°; therefore the congealed point of water has been fixed at 32°. of Fah.

The congealing points of ſeveral other ſubſtances have alſo been aſcertained with conſiderable accuracy. In ſome, however, it is not the congealing, but the melting, point that has been aſcertained. Theſe two points, if they be not quite the ſame, may naturally be ſuppoſed not to differ more than about a degree or two; hence from the latter the former may be eaſily deduced. In the following table, however, we ſhall ſet down the one or the other of thoſe points, according as either of them has been more accurately determined.

Table of the congealing, or melting points of different ſubſtances, expreſſed in degrees of Fahrenheit's ſcale; the high degrees of which have been eſtimated by the equivalent degrees of Wedgwood's thermometer,

Platina melts		23177°. F.
Manganeſe melts		28877.
Iron melts		21637.
Nickel melts		20577.
Pig iron begins to melt Cobalt melts		17977.
Fine gold melts		5237.
Settling heat of flint glaſs		4847.
Fine ſilver melts	according to Mr. Wedgwood	4717.
	according to Sir James Hall	3937.
Swediſh copper melts		4587.
Braſs melts		3807.
Zinc melts		700.
Lead melts	according to Newton	540.
	according to Seconat	585.
	according to Irvin	594.
	according to Parker	612.
Lead fixes, according to Crichton of Glaſgow		612°. F.
Biſmuth melts		460.
	according to Irvin	470.
A mixture of one part of tin and four of lead, melts		476.
Tin melts		408.
	according to Irvin	413.
	according to Crichton of Glaſgow, it congeals at	442.

The laſt mentioned gentleman ſays, "in melted tin the thermometer ſunk gradually till it arrived at 442°; then it inſtantly ſunk to 439°; and as inſtantly roſe to 442°. At this temperature the mercury remained perfectly ſtationary for five minutes, at which time the metal became ſolid to the centre of the crucible."

A mixture of three parts of tin and two of lead melts A mixture of two parts of tin, and one of biſmuth melts	334.
A mixture of tin and biſmuth, in equal parts, melts	283.
Sulphur melts	234.
A mixture of five parts of biſmuth, three of tin, and two of lead, melts	212.
A mixture of three parts of tin, five of lead, and eight of biſmuth, melts	219.
Serum of blood begins to coagulate at	156.
Albumen, or the white of an egg, coagulates at	156.
Bees wax melts	142.
Tallow melts	127.
Spermaceti melts	112.
Ice, or congealed water, begins to melt	32.

The increaſe of the bulk of water previous to, as alſo following, its point of congelation is a remarkable property, which has been more or leſs obſerved with all aqueous fluids, *viz.* they are contracted by cold, until a certain limit, which generally is about 7 or 8 degrees higher than their congealing point; they then expand again as they are cooled farther, and if they are not agitated, they will remain liquid at a temperature lower than their congealing point. The greateſt denſity of water, Count Rumford ſays, is ſomewhat lower than 40°. Profeſſor Hope of Edinburgh places it between 39°.5 and 40°. Mr. Dalton ſays, that the greateſt denſity of water is at the temperature of 42°.5. And that the expanſion of water is the ſame at the diſtance of the ſame number of degrees above and below 42°.5. Thus the expanſion is the ſame at 32° and 53°; the ſame at 10° and 75°, &c. The increaſe of bulk in freezing water is not owing to the formation of air bubbles, for water, which has been deprived of air, will alſo expand in freezing. The bulk of ice, at a mean, is to that of the water which it produces, as 9 to 8. This enlargement of bulk is attributed to a cryſtallization; the particles of water in freezing tend to arrange themſelves ſo as to form angles of about 60 and 120 degrees; and this tendency is exerted with a prodigious force. Mr. Leſlie ſays, "water neceſſarily diſcharges its air previous to the act of congelation; a circumſtance which ſometimes retards that ſpecies of cryſtallization. Hence it is, that water freezes ſooner which has been boiled. When expoſed to cold, crude water will preſent a cake of ice crowded with large bubbles entangled in the maſs; but boiled water will contain a ſolid lump, almoſt pellucid, with only ſome minute ſpecks or ſtriæ ſhooting from the centre." Dr. Black ſays, that boiled water begins to freeze as ſoon as the air has cooled it to 32°. Iron likewiſe occupies leſs room when fluid than when ſolid. And the ſame thing has been aſſerted of two or three other metallic ſubſtances.

Vinegar congeals at about - - - 28°. F.
Human blood congeals at - - - - 25.
Strong wines congeal at about - - - 20.
A mixture of one part of alcohol and three of water congeals at - - - - - 7.
A mixture of alcohol and water, in equal parts, congeals at - - - - - - - *minus* 7.
A mixture of two parts of alcohol and one of water, congeals at - - - - *minus* 11.
Mercury congeals at - - - *minus* 39.

Mercury expoſed to cold, and at about the point of congelation, contracts its bulk irregularly. This ſubſtance may be cooled ſome degrees below its freezing point, before it aſſumes the ſolid form; but as ſoon as it begins to harden, the thermometer riſes to its freezing point, which, from a variety of experiments made by Mr. Hutchins at Hudſon's Bay, appeared upon his thermometer to be —40°. "But (Mr. Cavendiſh obſerves in the Phil. Tranſ. vol. lxxiii. p. 321.) as it appeared from the examination of his thermometer, after it came home, that —40° thereon anſwers to —$38\frac{2}{3}$ on a thermometer adjuſted in the manner recommended by the committee of the Royal Society; it follows, that all the experiments agree in ſhewing that the true point at which quickſilver freezes, is —$38\frac{2}{3}$, or in whole numbers 39° below nothing."

In becoming ſolid, mercury ſometimes ſhoots into cryſtals or longitudinal filaments like pins. The firſt obſervations concerning the natural congelation of mercury were made by Mr. Gmelin about the year 1735, at Yeneſeick in lat. $58\frac{1}{2}$° north, at Yakutſk in lat. 62° north, at Rivengo, lat. $57\frac{1}{2}$° north, and elſewhere. (See the Peterſburg Commentaries for the years 1756 and 1765). Profeſſor J. A. Braun, of Peterſburg, in the year 1759, firſt accompliſhed the congelation of mercury by art, *viz.* by means of ſnow and aqua fortis. But with reſpect to the artificial methods of congealing mercury, and their hiſtory, ſee the article FREEZING.

Nitric acid is ſaid to congeal at - - *minus* 66.

With reſpect to the congelation of the ſulphuric, or vitriolic acid, the greateſt number of experiments ſeems to have been made by Mr. Keir, and from thoſe experiments he infers: "1. That the vitriolic acid has a point of eaſieſt freezing, and that this is when its ſpecific gravity is to that of water as 1780 to 1000. 2. That the greater or leſs diſpoſition to congelation does not depend on any other circumſtance than the ſtrength of the acid. 3. That the freezing and thawing degree of the moſt congealable acid is about 45° of Fahrenheit's ſcale. It is, however, to be obſerved, that this degree is inferred from the temperature indicated by the thermometers immerſed in the freezing and thawing acids; but the congelation of the fluid acid could never be accompliſhed without expoſing it to a greater degree of cold, either by expoſing it to the air in froſty weather, or to the cold of melting ſnow. 4. Like water, this acid poſſeſſes the property of retaining its fluidity when cooled ſeveral degrees below the freezing point; and of riſing ſuddenly to it when its congelation is promoted by agitation, or by contact even with a warmer thermometer. 5. That, like water and other congealable fluids, the vitriolic acid generates cold by its liquefaction, and heat during its congelation, though the quantity of this heat and cold remains to be determined by future experiments. 6. That the acid, by congelation, when the circumſtances for diſtinct cryſtallization are favourable, aſſumes a regular cryſtalline form, a conſiderable ſolidity and hardneſs, and a denſity much greater than it poſſeſſed in its fluid ſtate."

The heat of the earth, at leaſt on the ſurface of it, is derived entirely from the ſun; for the heat ariſing from combuſtion, as about volcanos, or from decompoſition of bodies, is trifling and partial. The direct rays of the ſun on the ſame ſpot of the ſurface of the earth heat it more or leſs, according to the time of the year, clearneſs of the atmoſphere, ſtate of the winds, colour and quality of the ſpot. In Great Britain, during the hotteſt time of the ſummer ſeaſon, the direct rays of the ſun ſeldom raiſe the mercury in the thermometer ſo high as 110°. But in other climates, eſpecially within the tropics, the mercury is raiſed conſiderably higher by the like expoſure. Yet we muſt not believe the idle ſtories of the ſun's heat melting lead, or ſetting fire to gun-powder, without the aſſiſtance of lenſes, ſpeculums, or other artifice.

It is not on account of the ſun's being nearer or farther from the earth, that we receive much more heat in the ſummer than in the winter time; ſince the difference of thoſe diſtances is too ſmall to be ſenſibly felt; but we receive more heat in the ſummer than in the winter ſeaſon. 1. Becauſe the ſun comes nearer to our zenith in the ſummer than in the winter time, in which ſituation its rays paſs through a ſhorter portion of the atmoſphere, and of courſe are leſs intercepted by it. 2. Becauſe, when the ſun is nearer to the zenith, a greater quantity of its rays falls upon a given horizontal part of the ſurface of the earth, than when that luminary ſtands lower, and its rays fall more obliquely upon the ſame ſpot. 3. Laſtly, becauſe the ſun remains longer above the horizon during a ſummer day than a winter one.

The hotteſt part of the day is not at noon, nor that of the year when the ſun paſſes neareſt the zenith of a given country; but the hotteſt part of the day, when no accidental circumſtance intervenes, is ſome time in the afternoon, and nearer to noon in the winter than in ſummer. In this country and in ſummer, the hotteſt part of the day generally is either preciſely at, or a little before, two o'clock. The hotteſt time of the year in this country generally takes place in July, *viz.* after the ſolſtice. The reaſon of this is, that though the rays of the ſun give more heat when the ſun ſtands higher, and of courſe at two o'clock they muſt give leſs than at noon; yet the earth, and the air contiguous to it, are hotter at two o'clock, becauſe, beſides the heat which they are actually receiving from the ſun, they retain a conſiderable portion of the heat acquired before that time; ſo that as long as they acquire at any particular time, a greater quantity of heat than they loſe of that which they had previouſly acquired, their temperature muſt continue to increaſe. The ſame thing muſt be underſtood with reſpect to the communication of cold, which, for ſimilar reaſons, is greateſt ſome time after midnight, and ſome time after the ſhorteſt days of the year. The earth acquires heat in the day time, and loſes it during the night. In the ſummer ſeaſon the loſs of heat during the night is leſs than the acquiſition of it during the day; therefore that exceſs of heat is gradually communicated from the ſurface to the more internal parts of the earth. But when the above-mentioned ſummer heat has penetrated a certain way, the winter cold begins to counteract it; and when that cold has penetrated a certain way, the next ſummer heat begins again to counteract it, and ſo on; hence, below a certain depth there is no alteration of temperature at any time of the year; unleſs ſome local combuſtion or other ſource of heat ſhould interfere, which, however, ſeldom occurs. This fixed degree of temperature at a certain depth below the ſurface of the earth, varies in different countries, and nearly coincides with the mean temperature of the particular country. Thus in London the mean temperature is 50°; and if a bucket of water be drawn from a pretty deep well, and a thermometer be inſtantly placed in it, the temperature of that water, (which is the ſame as that of the ground ſurrounding the bottom of the well) will alſo be found to be 50°. In proceſs of time the mean temperature of a country is liable to ſome alteration ariſing from cultivation, clearing of grounds, draining of marſhy grounds, &c. See Climate.

With reſpect to the temperature at different altitudes, it has been found that a thermometer placed cloſe to the ground is ſometimes affected by heat or cold, ſooner, or in a greater degree, than a thermometer placed 20, or 30, or 60 feet, higher up; and that at other times the latter is affected ſooner, or in a greater degree, than the former. In the night time, eſpecially when the air is ſtill, and the ſky quite free from clouds, a thermometer cloſe to the ground generally indicates a greater degree of cold than in a higher ſituation. The true cauſe of this phenomenon is not fully underſtood; though it is attributed to evaporation, or according to Mr. Six, to the coolneſs which the dews or vapours may acquire in their deſcent.

At great heights above the ſurface of the earth, either in the free air, or on the ſummit of high mountains, the cold is much greater, and it increaſes more ſuddenly; 1ſt, becauſe they are much more expoſed, and 2dly, becauſe they are more remote from the body of the earth, which, as has been obſerved above, tends to equalize the temperature, by retaining in the winter time a conſiderable degree of the heat acquired in the courſe of the ſummer. The winds to which mountains are expoſed, eſpecially thoſe which, after having blown over the plains below, riſe along their ſides, have a peculiar refrigerating power, ariſing from the expanſion of the aſcending air, which becomes capable of abſorbing more heat in proportion as it is more rarefied. See Dr. Darwin's Paper, Phil. Tranſ. for 1788.

Thus we have briefly ſtated the natural ſources, and the principal cauſes which check or promote the heat and the cold, that are uſually experienced in the world, at different times of the day, of the year, and in different countries; whence alone one may pretty well conceive where and when natural congelation may be expected to take place. Yet it is neceſſary to ſubjoin ſome farther obſervations, that have been made with reſpect to natural congelation at different times and different places.

The greater obliquity with which the ſun's rays fall upon the northern and ſouthern parts of the earth, than they do upon ſuch parts as are near the equator, undoubtedly produces the variety of the mean temperatures that are obſerved in different latitudes; the higher latitudes being generally colder than the lower, and *vice verſâ*. But this gradation is partly counteracted by a variety of local circumſtances; and ſuch are the vicinity of large tracts of land or great extent of ſea, the face of the country being flat or hilly, the diſpoſition of the hills and mountains, the prevalence of rain and of certain winds, the ſtate of cultivation, &c. The influence of winds in certain latitudes is ſo very great that a froſt or thaw is brought on within a remarkably ſhort time by a change of the wind. The action of winds on the temperature of a country principally depends upon three circumſtances, *viz.* on their bringing a quick ſucceſſion of new air in contact with the bodies that are expoſed to it, on their having paſſed over the ſurface of hotter or colder tracts of water or land, and upon their increaſing the evaporation. Sauſſure found that when the wind moves at the rate of forty feet per ſecond, it triples that quantity of evaporation that would take place in calm air; hence it follows that frequently unuſual heats or colds come on at unexpected times, and that the higher ſtrata of the atmoſphere are often warmer than the lower; for the heat of the atmoſphere is derived not from the immediate action of the ſun's rays which paſs through it, but from the warmer and more ſolid bodies with which it has been, or is, in actual contact. In conſequence of theſe various circumſtances, it has been obſerved that the north Pacific Ocean, above latitude 40°, is much colder than the north Atlantic, between the ſame parallels of latitude. The interior parts of Siberia, eaſt of longitude 100°, are much colder than the parts equally diſtant from the meridian on the weſtern ſide. The coaſt and interior parts of the weſtern regions of America are much colder above the latitude of 40°, than the correſponding tracts of the continent of Europe. Large ſeas, which are agitated by winds and currents, are thereby ſo little affected by cold winters or hot ſummers, as to preſerve a temperature nearly uniform in every ſeaſon, like the internal parts of the earth.

With reſpect to the mean temperature of places at different altitudes above the level of the ſea, but in the ſame country, or nearly about the ſame ſpot with reſpect to latitude, the heat diminiſhes nearly one degree of Fahren. for every 200 feet of elevation, according to Dr. Black. Other writers find reaſons to aſſert, that the diminution of one degree takes place at every 299 feet of elevation.

From the ſtatement of all the above particulars the reader may form ſome idea of the time and place when natural congelation may be expected, and he will at the ſame time be able to perceive that cloſe to the ſurface of the earth, no great regularity can be expected. On the continent of Europe congelation formerly took place at a lower latitude than it does at preſent, when natural congelation is ſeldom obſerved lower than the latitude of 40°. In America congelation has been obſerved at a much lower degree; and it is remarkable that great degrees of heat, as well as great degrees of cold, are alternately experienced on the ſame ſpots of that continent. In the more northern parts of the world the degrees of cold are very extraordinary. At Torneao, Reaumur's ſpirit thermometer fell to minus 34°. In Siberia the ſpirit thermometer has been known to deſcend as low as minus 121°. Even at the Glaſgow obſervatory in the year 1780, the mercury of the thermometer expoſed to the ambient air was found to ſtand at minus 14°.

The altitude on the ſides of mountains, at which conſtant congelation takes place, ſeems to be leſs fluctuating, though not accurately aſcertained. This altitude varies with the latitude; but even in the torrid zone perpetual congelation has been obſerved (according to Bouguer and others) at the altitude of about 15600 feet. This altitude, at which the congelation is conſtant, or where water ceaſes to be a fluid, and beyond which viſible vapour does not ſeem to aſcend, is called the *upper line of congelation*. The *lower line of congelation* is where it freezes at night only. The upper line of congelation, within the tropics, has been obſerved at the altitude of 15600. Near the tropics, on the ſides of the temperate zones, it lies at the height of about 13428 feet. On the iſland of Teneriffe, in lat. 28° N., it lies at the altitude of about 10000 feet. In Auvergne, lat. 45° N., the line of congelation is at the altitude of 6740 feet. In latitude between 51° and 54° N. it ſeems to be at the altitude of about 5800. In latitude 80° north, lord Mulgrave found the line of congelation at the altitude of about 1200 feet above the level of the ſea; whence, if the progreſſion continues uniformly, as general Roy obſerves, we may conclude that the ſurface of the earth, at the pole itſelf, is for ever covered with congelation. Mr. Kirwan, however, places the upper line of congelation conſiderably higher. See his paper on the variations of the atmoſphere, in the 8th vol. of the Tranſ. of the

Royal Iriſh Academy. He reckons the altitude of the line of congelation from 0° to 10° of north latitude, at about 27700 feet; from 10° to 15° at about 26400 feet; from 15° to 20°, at about 25200 feet; from 20° to 25°, at about 24000 feet; from 25° to 30°, at about 22000 feet; from 30° to 35°, at about 20000 feet; from 35° to 40°, at about 17000 feet; from 40° to 45°, at about 15000 feet; from 45° to 50, at about 12500 feet; and for every one of the other degrees of latitude, at the altitudes which are annexed to them in the following table. Theſe reſults, however, he deduced by computation from a few aſcertained particulars.

Degrees of N. lat.	Altitude of the line of congelation.	Degrees of N. lat.	Altitude of the line of congelation.
51°	10124	71°	4354
52	8965	72	4295
53	7806	73	4236
54	6647	74	4177

70	4413	90	3432

CONGENERES *muſculi*, in *Anatomy*, are ſuch muſcles in an animal body, as ſerve together to produce the ſame motion; and they are ſo called becauſe they aſſiſt one another in their action.

CONGER, or CONGER-EEL, in *Ichthyology*, the largeſt of the Muræna tribe. This voracious fiſh grows to the length of five or ſix feet, and the thickneſs of a man's thigh. The colour of the upper part is dark grey, ſometimes inclining to olive, and the belly pure white; but it is principally diſtinguiſhed from the other ſpecies of the muræna genus by having the lower jaw rather ſhorter than the upper; noſe with two tentacula, and the lateral line whitiſh, with a row of ſpots. See MURÆNA.

CONGERIES, a Latin word, ſometimes uſed in our language for a collection or heap of ſeveral particles, or bodies, united into one maſs or aggregate.

CONGERIES, in *Rhetoric*. See SYNATHROISMUS.

CONGESTION, in *Medicine*, has been uſed to denote an enlargement of any part of the body, eſpecially when accompanied with hardneſs, or alteration of ſtructure, which, in the opinion of the humoral pathologiſts, was produced by a collection of morbid humours, depoſited in the part. The term is ſtill employed, chiefly to expreſs the morbid increaſe of diſtention in the blood-veſſels in inflamed parts, or morbid effuſions of blood or lymph in the viſcera. Thus, a *congeſtion* of blood in the veſſels of the brain is ſaid to have produced apoplexy, when, on diſſection, veſſels which are uſually inviſible, are obſerved to be filled with red blood; and congeſtion is ſaid to exiſt in the lungs, when the circulation of the blood through the minute ramifications of the blood-veſſels is impeded, or when lymph is poured out into the cells of the bronchiæ, as in the catarrhus ſenilis, and peripneumonia.

CONGHE' LAKE, in *Geography*, a lake of Thibet, which intervenes between the Mangarvar lake, and the head of the river Sanpoo.

CONGIARUIM, CONGIARY, among *Medaliſts*, a gift or donative, repreſented on a medal.

The word comes from the Latin *congius*; becauſe the firſt preſents made to the people of Rome conſiſted in wine and oil, which were meaſured out to them in congii. The congiary was properly a preſent made by the emperors to the people of Rome. Thoſe made to the ſoldiers were not called *congiaries*, but *donatives*.

The legend on medals repreſenting congiaries, is *congiarium*, or *liberalitas*.

Tiberius gave a congiary of three hundred pieces of money to each citizen: Caligula twice gave three hundred ſeſterces a head. Nero, whoſe congiaries are the firſt that we find repreſented on medals, gave four hundred. The congiarium of Nerva had on its reverſe five figures.

CONGIO, or CUNGIO, CAMILLO, in *Biography*, was a deſigner and engraver of conſiderable talents. He was born at Rome about 1604. Little is known of his life, except that he followed his profeſſion at the place of his nativity, and at Florence. About the year 1630, he engraved ſeveral of the plates for the Galleria Juſtiniana. Moſt of the twenty plates for Taſſo's Jeruſalem, from the deſigns of B. Caſtelli, are by Congio, as likewiſe ſeveral of the engravings in the fine work entitled Odes Barberinæ. Beſides the above, we have many prints by him executed in a bold and firm manner, from the deſigns or pictures of Tempeſta Lanfranco, Pomerancio, and other maſters, and ſome from his own drawings. His plates are generally marked with two C's, the top of one joined to the bottom of the other; or in this manner: C. C. F. the F. ſtanding for fecit. Strutt. Huber, Manuel des Arts.

CONGITELLA, in *Antiquity*, half a congius.

CONGIUM, in *Ancient Geography*, a town of Spain, placed by Ptolemy in the Tarragonenſis territory; the country of the Vaccæans, ſuppoſed to be the preſent Cabeçon.

CONGIUS, an ancient Roman meaſure of capacity, or for things liquid, = $\frac{1}{8}$ of a cubic old Roman foot, = 8 ſextaries, = 197.137 cubic Engliſh inches, = .1141 cubic Engliſh feet.

From the original ſtandard of Veſpaſian extant at Rome, Greaves deduced the value of the Roman pound to be 5256 Troy grains. See DENARIUS. But Mr. Raper, in an excellent paper on this ſubject, has ſuggeſted ſeveral objections againſt the accuracy of this concluſion. Phil. Tranſ. vol. lxi. part ii. p. 496.

The congius has alſo been uſed in England, as appears by a charter of king Edmund in 946.

CONGLETON, in *Geography*, a ſmall corporate town in Cheſhire, England, is ſituated near the upper part of the river Dane, on the borders of Staffordſhire, and governed by a mayor and ſix aldermen. It poſſeſſes two churches, both ſubject to the mother church of Aſtbury, a village two miles diſtant. The town was formerly celebrated for the manufacture of tagged leather laces, called Congleton points; but the chief employment of the poor is now derived from a very capital ſilk mill erected on the river; and from a ribbon manufactory. In the church-yard of Aſtbury are two ancient ſtone monuments, ornamented with the inſignia of knighthood; but the families whoſe memory they were intended to record are now unknown. Congleton is 163 miles N.W. from London; has a market on Saturdays.

In the return under the late act the houſes were eſtimated at 855, the inhabitants at 3861, of whom 1713 were males and 2148 females.

CONGLOBATE *glands*, in *Anatomy*, thoſe glands whoſe ſubſtance is not divided, but firm, entire, and continued; and their ſurface ſmooth and uniform.

They are thus called, in oppoſition to *conglomerate* glands. Conglobate glands have each of them an artery which brings them blood, a vein which carries it back again, after the proper juice has been filtrated, and ſeveral excretory ducts.

Some of them have a cavity in the middle, with lymphatic veſſels, which diſcharge themſelves into a common reſervoir, or canal.

CONGLOBATE *flowers*. are thoſe with globular heads.

CONGLOMERATE *glands*, are thoſe which are compoſed of ſeveral little ones; or they are ſeveral glandulous bodies joined together under the ſame common membrane. See GLAND.

Such are the ſalival glands, lachrymal glands, the pancreas, &c. which ſee under their proper articles.

The conglomerate glands, beſides their arteries, veins, and nerves, are alſo furniſhed with an excretory veſſel, ramified throughout their own ſubſtance; by means whereof they diſcharge the liquors they have filtrated into reſervoirs.

CONGLOMERATE *flowers*, are thoſe which are irregularly crowded together.

CONGLOMERATION, in *Mineralogy*, is the term uſed to expreſs confuſed mixtures or concretions of different mineral ſubſtances. Kirwan's Geol. Eſſays, p. 303 and 306.

CONGLUTINATION, the act of gluing, or faſtening two bodies together, by the intervention of ſome third, whoſe parts are unctuous and tenacious, in the nature of a glue, *gluten*; from whence the word is formed.

In the animal œconomy, the parts of the body are ſaid to be conglutinated by means of their natural moiſture; by the help of bandages, as in ſeveral caſes of ſurgery; or by the ſupply of viſcid particles. In which laſt acceptation, conglutination differs little from accretion, or nutrition

CONG-MOU-ING, in *Geography*, a town of China, in the province of Se-tchuen; 42 miles N.W. of Hoei-li.

CONGO, or KONGO, a name given to the country of Africa, otherwiſe called *Lower-Guinea*, which ſee. It is commonly divided into Loango, Angola, Benguela, and Congo Proper.

CONGO, or KONGO, *Proper*, a kingdom of Africa, bounded on the north by the famous river Zair or the river of Congo, which divides it from that of Loango, on that ſide; on the ſouth by that of Dando, which ſeparates it from the kingdom of Angola; on the eaſt by the kingdoms of Fungono and Metamba, and the burnt mountains of the ſun, thoſe of cryſtal or ſalt-petre and ſilver, and by the rivers Verbela and Chilandea; and on the weſt by the Ethiopic ſea, called the ſea of Congo. Its extent from N. to S. and from E. to W. has not been accurately aſcertained; but according to the relation of John Anthony Cavazzi de Monte Cuculo, a Capuchin miſſionary, the dominions of the kings of Congo were much extended towards the eaſt and the ſouth, before the introduction of the Chriſtian religion; but ſince this event, many of the remote provinces in theſe directions have been diſmembered, ſo that Congo was reduced from above 600 leagues in circuit to leſs than one-half of that extent. Being ſituated under the torrid zone, it is ſubject to the exceſſive heats peculiar to that climate; however, they are conſiderably mitigated by winds and breezes, rains and conſtant dews; as well as by the more equal length of days and nights. Their ſummer and winter, which compoſe their year, are divided into ſix ſeaſons, which they call maſſanza, neaſu, ecundi, quitombo, quiliſo, and quimbangala. The firſt commences with the month of October; which is the beginning of their ſpring, when the rains begin to fall; and they continue during the two, and ſometimes the three, next months. The floods that are thus occaſioned are commonly followed by a famine. Their ſecond ſeaſon begins about the end of January, which is followed by harveſt and new ſowing; their lands commonly yielding them two harveſts. The third and fourth ſeaſons are frequently blended towards the beginning of March, when the more gentle rains begin to fall and continue till the month of May; at which time the air is clear and dry, but occaſional clouds burſt forth into tremendous lightning and thunder without rain; theſe two ſeaſons laſt till about the beginning or ſometimes till the end of September. The two laſt ſeaſons conſtitute their winter, which conſiſts not in froſt or ſnow, for theſe are unknown in this climate, but in dry blaſting winds, that ſtrip the earth and trees of their verdure, till the next maſſanza, or ſpring, reſtores their vernal bloom. The Congoeſe divide the year into twelve lunar months, commencing like that of the Jews, in September. Their week conſiſts of four days; three of which are appointed for labour, and the fourth for reſt or religious exerciſes. The general indolence of the inhabitants prevents their deriving any ſubſtantial benefit from the fertility of their ſoil, which duly cultivated would yield a double, and ſometimes a triple, crop yearly. But the negroes, averſe from labour, ſpend their time in dancing, leaping, hunting, and ſhooting, or in ſmoaking and more liſtleſs indolence; whilſt they commit to their ſlaves, or their wives, the operations of digging, ſowing, reaping, cutting woods, grinding corn, and fetching water. Their ground produces variety of grain, but no corn or rice beſides that which is cultivated by the Portugueſe. Of their maiſe, of which they have regularly two crops, they make their bread. They have three other ſorts of grain, which they apply to the ſame purpoſe. They alſo cultivate a variety of pulſe, as beans and peaſe of different ſorts, which ſerves them for part of their food. Their fruit-trees have been chiefly trees planted there by the Portugueſe; and of palm-trees, which are exotic and brought from America, they have no leſs than eight ſorts, which are all excellent in their kind. If we may credit the accounts that are given of the productions of the country, which ſometimes border on the fabulous, they have a tree called Aliconda, ſo large that ten men cannot fathom it, yielding a fruit which reſembles a gourd, and which ſerves for veſſels of various uſes; the bark of which furniſhes them with a coarſe thread, which they form into ropes and into a cloth, with which the natives cover their middle from the girdle to the knees; and the ſmall leaves of which ſupply them with food in a time of ſcarcity, while the large ones are uſed for covering their houſes, or by burning for the manufacture of good ſoap. Of the bark of the infanda tree, and alſo of the mulemba, reſembling in many reſpects our laurel, they form a kind of ſtuff or cloth, which is fine and uſed for cloaks and girdles by perſons of the higheſt rank. The oil of their palm-trees is uſed inſtead of butter; with the moſs that grows about the trunk, the rich commonly ſtuff their pillows; and the Giagas apply it to their wounds with good effect: with the leaves the Moors cover their houſes, and they draw from theſe trees, by inciſion, a pleaſant liquor like wine, which however turns ſour in five or ſix days. From the Congo palm-tree, ſo called, becauſe it thrives better in that country than any of the other ſorts, they obtain a liquor, which is reckoned as valuable as the wine that is brought from Europe, though it is rather a kind of milk, ſweet and agreeably tart, which will become ſour in three or four days, and is ſo ſtrong and heady, that a pint of it will produce intoxication. The fruit of this tree, not unlike a peeled cheſnut in colour, taſte, and ſubſtance, is the common food of the poorer claſs. With the oil that is drawn from it the natives dreſs their victuals; but the Europeans only burn it in their lamps. Of their ſhrubs we ſhall only mention that which they call capano, or "the fig of hell," from the nut of which they extract an oil for the lamp, and which they alſo uſe in the compoſition of their ointments and plaſters. The leaves burnt to aſhes, afford a good lye, with which the natives waſh their bodies. The Portugueſe have taken care to plant ſeveral other fruits, as oranges, lemons, citrons, granates, cedars, and others, which thrive as well as in their native ſoil. Vines have alſo been brought hither from Candia; and they yield excellent grapes twice a year. They have alſo plants of the aromatic kind, which yield ſubſtitutes for cinnamon and pepper. Their manioc, of which they make bread, is the ſame which is uſed in Aſia and America; their potatoes and other roots of a like kind yield a grateful nouriſhment. Wheat is the only grain which the ground will not produce, as it ſhoots up into ſtraw and ear, the former being high enough to hide a man on horſe-back and the latter being unfilled. Their graſs grows to a great height, and affords ſheltering places for a variety of wild and voracious beaſts, and venomous inſects; ſo that it is dangerous to travel through the country on this account. Their lilies, tulips, tuberoſes, hyacinths, &c. grow wild, and are ſingularly beautiful.

The principal rivers of this country are the Zair, into which fall the Bancaro, Vambra, Coungo, and Barbela or Vervel, the Dando, which ſee reſpectively. Between the Zair and Dando, are the Lchunca, Doce, Ambriz, Loze, Onzo, and Lutana, with ſeveral others of leſs note.

Congo is divided into ſix large provinces, under the titles of duchies, counties, and marquiſates, and theſe again are ſubdivided into leſſer ſigniories or lordſhips. The ſituation of theſe provinces is as follows; along the ſea coaſt lie the county of Sogno, and the great duchy of Bamba; on the north, the duchy of Sundi, and the marquiſate of Pango; on the weſt, the duchy of Batta; and within land, the marquiſate of Pemba. See each reſpectively. The capital of the whole kingdom is Banza, or St. Salvadore, which ſee. Independent of the ſix diſtricts above enumerated, Congo has ſeveral other leſſer provinces, moſt of which are covered with foreſts or mountains, and inhabited by a race of men in a barbarous and ſavage ſtate: their names, as we learn from Cavazzi, are Zuiona, Zujamazondo, Ndamba, Nſuſſo, Nſellajuva, Alombo, Nſolo, Nzanga, Marſinga, and Mortonda; the three laſt of which border upon the country of Ajacoa, a nation more barbarous than any of the reſt.

The kingdom of Congo, like moſt other parts of Africa, breeds a prodigious variety of living creatures, both wild and tame, and particularly thoſe of the former ſort; ſuch as elephants and lions, of a monſtrous ſize, leopards, tygers, wolves, and other voracious animals. The zebra of this country is a beautiful animal, which the natives hunt, on account of its fleſh, which they eſteem a dainty food, and for its hide which they ſend to Europe as a valuable commodity. In this country they have alſo a great abundance of buffaloes and wild aſſes. The "Dante" ſeems peculiar to this country; in ſhape and colour it reſembles an ox, but is not ſo large; its horns are like thoſe of a he-goat, but very ſmooth and ſhining, and of a blackiſh hue, of which the natives make a variety of pretty baubles; the ſkin is commonly bought by the Portugueſe, and ſent into Germany, to be tanned and made into targets, called "Dantes;" and of the raw hide dried, the natives make their ſhields, which are impenetrable to arrows and darts, and ſo large as to cover the whole body. Cameleons ſwarm in Congo; and it has ſeveral ſorts of wild rats, as the ningi, nſoſſi, and maimoni, whoſe furs excel thoſe of the fineſt tygers, in the beauty, variety, and regularity of their ſtreaks and ſpots. The foreſts alſo ſwarm with wild dogs, which are extremely fierce and voracious. It has alſo one ſingular quadruped, which abides conſtantly in the trees, and which is ſaid to die immediately upon ſetting its feet on the ground; it is called "entiengia," and is very ſmall; its ſkin is ſo beautifully ſpotted, that none but the kings of Congo, the princes of the blood, and ſuch nobles as obtain the privilege from him, have the liberty of wearing it. And even the kings of Lovango, Cacongo, and Gay, receive this extraordinary fur, as a valuable preſent.

The tame animals of Congo, ſuch as oxen, ſheep, hogs, horſes, mules, and aſſes, which might be rendered uſeful and profitable, are much neglected. The Portugueſe, however, have directed their attention to the cows, ſheep, and goats, chiefly on account of their milk, though they have not learned to make butter or cheeſe. The land and ſea fowls of this country are very numerous; its oſtriches are very large and beautiful; the feathers of which, mixed with thoſe of peacocks, no leſs numerous and beautiful, are uſed, inſtead of enſigns and ſtandards, and made into umbrellas. Turkies, geeſe, hens, and ducks, both wild and tame, and alſo pheaſants, pigeons, doves, woodcocks, and other ſmaller birds, abound in this country. Of parrots there is a great variety, diſtinguiſhed both by their ſize and colour; the moſt eſteemed of theſe are ſuch as they denominate, by way of excellence, the birds of muſic, which are kept by perſons of rank in cages and aviaries, for the ſake of their ſurpriſing melody. Here are other birds which the ſuperſtitious natives regard with horror; the flight or cry of which throws them into a general panic, and occaſions them to diſperſe with the utmoſt precipitance and confuſion. The moſt dreaded of the ominous kind are crows, ravens, bats, owls, and eſpecially the great owl, which they call, in their language, "kariam pemba," the name they give to the devil. Birds of prey, ſuch as eagles, vultures, falcons of various ſorts, ſparrow-hawks, and others of a ſimilar kind, are found in great numbers. Herons, bitterns, and ſome others of the like voracious kind, commonly abound in their marſhes, lakes, and other waters. Among theſe they have a bird, in ſhape and ſize like a crane, and one in particular, called by the Portugueſe the pelican, of a large ſize and whitiſh colour; and alſo another called the fiſher, which darts from a ſurprizing height in the air on the fiſh which he perceives in the ſea or in rivers. Of fiſh, the ſea adjoining to this country, and its rivers, afford great plenty and variety. The inhabitants are likewiſe infeſted with a great variety of ſerpents, very long and thick, rattle-ſnakes, vipers, and other venomous reptiles, ſcorpions, and other venomous inſects, both flying and reptile, of various kinds, are found in this country. This country is ſaid to poſſeſs mines of ſilver and gold, as well as of iron and copper; but the people are too indolent to work them, or to derive any great advantage from them.

When the Portugueſe firſt diſcovered this country, in the reign of John II., in the year 1484, they found it for the moſt part covered with towns and villages, ſwarming with inhabitants; the cities being well filled with people, and particularly the metropolis, which contained above 50,000 perſons. We may form ſome judgment of the population of the country by this circumſtance, *viz.* that the army of the king of Congo, in the year 1665, conſiſted of no leſs than 900,000 fighting men; and, beſides, the number of converts to Chriſtianity, which a ſmall number of Capuchin friars made among the more civilized ſort, within the ſpace of a few years, is affirmed to have amounted to 600,000. The ſurpriſing fecundity of their women, the hardineſs with which they bring up their children, and the robuſt healthy conſtitution of their men, if we may credit Cavazzi, and the miſſionaries, are ſuch that their villages and hamlets ſo ſwarm with men, women, and children, that a father will exchange one or two of the latter for ſome commodity he wants, or even ſome trifling bauble which he fancies; inſomuch that the number of ſlaves they ſell abroad, doth ſeldom, communibus annis, fall ſhort of 15 or 16 thouſand. Notwithſtanding the indolence and conſequent poverty of the Congoeſe, they entertain the moſt extravagant conceit both of themſelves and of their country; ſo that it is one of the articles of their belief, that the reſt of the world was the work of angels, but that their kingdom of Congo, in its full and ancient extent, was the immediate production of the Supreme Architect himſelf, and muſt of courſe enjoy ſingular advantages and prerogatives above all others; and that their monarchs muſt be the moſt opulent, wiſe, and powerful, and their ſubjects the nobleſt, richeſt, moſt ingenious, and happieſt in the univerſe. They imagine alſo, that the natives who traffic with them are forced to undertake that ſervile employment by their poverty and the ſterility of their reſpective countries, rather than induced to it by their luxury and avarice; whilſt they themſelves, with the utmoſt eaſe and content, can indulge their natural indolence, though attended with hunger and miſery, rather than diſgrace the nobleneſs of their blood by any kind of induſtry; which, however laudable and beneficial, is regarded by them as a leſſer degree of ſlavery. However, ſince the ſettlement of the Portugueſe, they have been rouſed by their example from this kind of fantaſtic pride and ſhameful ſloth into occaſional and partial exertion; in weaving nets, and other coarſe ſtuffs, ſawing of boards, ſeveral branches of carpentry, and other manufactures and trades. But though they think it beneath their dignity to apply to any uſeful work, they deem it no diſgrace to beg and ſteal.

The complexion of the genuine natives, that both of the men and women, is black, but ſome of them are of a deeper dye than others. Since their intermarriages with the Portugueſe, they have varied from their native hue; ſome to a dark brown, ſome to an olive, and others to a blackiſh red. Their hair is black and curled, and in ſome caſes of a dark ſandy; their eyes are generally of a fine lively black, but ſome are of a dark ſea-colour; they have neither flat noſes nor thick lips, like the Nubians and other negroes; their ſtature is moſtly of the middle ſize; and, excepting their black complexion, they much reſemble the Portugueſe, though ſome of them are more fat and fleſhy. In their diſpoſition, they are generally miſtruſtful, jealous, envious, and treacherous, and much inclined to revenge. They are ſo far devoid of natural affection, that a father will ſell his ſon or daughter, and perhaps both, for a piece of cloth, a collar or girdle of coral or beads, and often for a bottle of wine or brandy. A huſband may have as many wives, or if a Chriſtian, as many concubines, as he pleaſes, and repudiate, or even ſell them, though with child, at his pleaſure. The religion of the country, before the Portugueſe introduced their Chriſtianity into it, was, and ſtill is, among the unconverted, a monſtrous compound of idolatry and ſuperſtition, and of the moſt abſurd and deteſtable rites and cuſtoms, invented by their "gangas," or prieſts, for the purpoſe of keeping the people in a ſtate of the moſt abject ſubjection, and cruel tyranny and wretchedneſs. They do, indeed, acknowledge one ſupreme being, called "Nzambiamponga," believed to be all-powerful, and to whom they aſcribe the creation of their country; but they ſuppoſe that he has committed the care and government of all ſublunary things to a great variety of ſubordinate or inferior deities, appointed to preſide over the air, ſea, and earth; lakes and rivers, winds and ſtorms, rain, lightning, drought, heat and cold, men, beaſts, fowls, and fiſhes, trees, fruits, and other productions of nature, fertile and barren, healthy and ſickly ſeaſons. Hence proceeds that immenſe multitude of falſe deities, idols and altars, and that prodigious variety of gangas or prieſts, and ſuperſtitious rites, ſtill found in thoſe parts of the kingdom, where Chriſtianity has not been introduced. Theſe imaginary deities are repreſented under various forms, at the pleaſure of the worſhipper, either of living creatures, as ſerpents, crocodiles, lions, tigers, he-goats, &c. or of trees and plants of different kinds, or of ſtatues and images, ſkilfully carved or painted, ſome of which they worſhip in their houſes, and others in temples of mean conſtruction. Their worſhip conſiſts in genuflexions, proſtrations, fumigations, and other ſuch ſuperſtitious rites; and alſo, agreeably to the injunctions of the gangas, in offerings of their moſt valuable effects, for food, apparel, &c. from which the principal revenue of the gangas is derived, who contrive to ſell the favour of theſe deities at the moſt exorbitant price. Such is the ſuperſtition of the people, and the unbounded influence of theſe gangas, that they will not attempt to build a houſe or hut without conſulting ſome ganga, and putting the edifice under the protection of a deity; nor can the owner take poſſeſſion of it without employing the ganga to make the neceſſary ſacrifices and fumigations, and performing other ceremonies, in order to ſecure that protection. Even the giagas, who are the moſt barbarous people of this kingdom, never venture to begin their harveſt till they have offered various, and even human victims to their gods, and gorged their gangas themſelves with human fleſh. Excepting their new moons, they have no ſet feſtivals or ſeaſons of worſhip, beſides thoſe which the preſident of the gangas appoints, after a victory, a good harveſt, &c. to whom it belongs, to appoint the attendant ſacrifices and rites, to receive the offerings of the people, and to preſcribe the various ceremonies which accompany them. The higheſt power and dignity, pertaining to the prieſtly tribe, are thoſe which are veſted in the "ſhalome" or "chalombe," whom the people reverence as a kind of deity, and to whoſe rank and office various privileges belong. The influence of the gangas is ſo extenſive and ſo powerful, that the kings of Congo, though deſirous of extirpating idolatry from their dominions, have been unable to effect it. With regard to the eſtabliſhment of Chriſtianity in the kingdom of Congo, the firſt preachers commiſſioned by the court of Portugal for this purpoſe, were prieſts and monks of the church of Rome; ſo that the Romiſh religion became the eſtabliſhed religion of all the conquered provinces of the kingdom. But Chriſtianity, even under that form of it, has been ſo much neglected, that in the greater part of theſe extenſive dominions, nothing now remains but the mere name of Chriſtian. It is ſaid, indeed, that the catholics in the duchy of Sogno, are better Chriſtians than others, as they pay a peculiar regard to the external forms of the popiſh worſhip. The princes of this province, as well as thoſe of Bamba and Pemba, have always diſtinguiſhed themſelves by their zeal for the Chriſtian religion, under that external mode of it in which they have been inſtructed; and they have been careful to preſerve their reſpective governments from being corrupted by the heatheniſh gangas or prieſts; and if any ſuch are ever found within their dominions, they are treated with a ſeverity, which prevents their attempting to repeat their viſits.

The government of Congo is monarchical and deſpotic. The kings are the ſole proprietors of all the lands within their dominions; which they parcel out to individuals on condition of a certain tribute and of the performance of particular ſervices. The tribute is ordered to be brought in once in three years at the fartheſt; and the rigorous demand of it is the cauſe of many cruel extortions, which often terminate in a revolt, or open rebellion. The crown is partly hereditary, and partly elective, ſo that no candidate can be choſen, unleſs he be of the royal blood; and ſince the introduction of Chriſtianity, a Chriſtian of the church of Rome. The whole proceſs of his coronation and his mode of living after his advancement to the throne are attended with various circumſtances of ſplendour and magnificence. Whenever he goes abroad, which is ſeldom the caſe, he is attended by a numerous guard, conſiſting of Anſiki (See ANSIKO), and ſome others of neighbouring nations in whom he repoſes the greateſt confidence, muſicians, knights of the holy croſs, (an order inſtituted by the firſt Chriſtian king of Congo) and a number of officers, richly accoutred. The reſpect that is paid him approaches to idolatry. His court is numerous and brilliant; and the royal palace is ſpacious, grand, and commodious. His ſeraglio, in which he keeps a great number of concubines, though he is allowed only one wife, is a kind of priſon; as the women that enter it are confined during the remainder of their lives. His lawful wife preſides in the ſeraglio over all the other women; who indulge themſelves in the moſt licentious gratifications. The royal revenue conſiſts chiefly in the tribute that is paid him by ſeveral vaſſal princes; free-will offerings, in acknowledgment of the lands which are held under him; the property of all the zimbis, or cockle-ſhells, that conſtitute the current coin of this and other neighbouring kingdoms; mines of ſilver and gold, which, however, are much neglected; and the renewal of fiefs and inveſtiture, fines and confiſcations. He has alſo the prerogative of levying taxes upon his ſubjects whenever he pleaſes. His ſtanding forces are neither numerous, nor well-diſciplined, and very badly armed and clothed. Their mode of fighting is tumultuous and ferocious, nor do they give any quarter. Thoſe that are taken alive are hurried to the ſea-ſide, or to ſome inland market, where they are ſold for ſlaves to the Europeans. The funeral obſequies of the monarchs of Congo before they were converted to Chriſtianity, conſiſted of various kinds of ſacrifices and ſuperſtitious ceremonies, accompanied with muſic, howling, dancing, and feaſting, which laſted a whole week, and were reſumed once a year, on the anniverſary of the king's demiſe. It was alſo the cuſtom to bury alive a certain number, nor exceeding twelve, of his favourite concubines, or young ladies belonging to his court; but Chriſtianity has aboliſhed this inhuman cuſtom, though it has not ſuppreſſed the drunken revels that take place on this occaſion.

It is conſidered as a great crime and liable to puniſhment on conviction to ſhed tears even for the king. But certain perſons are kept in pay to go to all the public places of the city or town, to remind the ſubjects of his death by the mournful ſound of their ivory cornets. The princes and nobles are interred in wainſcotted vaults hung with black; and two of their old domeſtics deſtined alternately to guard the entrance, and to pray for the deceaſed. Other prayers are to be offered on the anniverſary of their deceaſe, and on All-ſouls day, at which times their graves are opened, and the hangings exchanged for new ones. The giagas dance about the graves of the deceaſed in a frantic manner, and bring them victuals, drink, and other conveniences. The dances that are performed at the funeral of their great men laſt eight whole days, without intermiſſion: and upon theſe occaſions, they never fail ſacrificing a number of human victims, the fleſh of which they devour with peculiar reliſh. Mourners of the common claſs ſhave their whole heads, and anoint themſelves with oil, upon which they rub ſuch a quantity of earth and duſt, and dried leaves, as to give them a ſhocking appearance. Thoſe of higher ranks ſhave only the upper part of their heads and bind it with a liſt of cloth, linen, or leather, and confine themſelves to the houſe for eight whole days. The Congoeſe conceive concerning dying perſons that they are juſt paſſing from a wretched life into a ſtate of tranquillity and happineſs; and therefore they think they cannot act a kinder part than to accelerate their deliverance. Among the vulgar this notion leads to the barbarous practice of ſtopping the mouth and noſe of a dying perſon, and thumping upon the breaſt with violence, that he may the ſooner paſs into a ſtate of felicity.

The Congoeſe have no written laws; but cuſtom and tradition ſerve them inſtead of a code and commentaries, unleſs favour or bribery interpoſe. Every province has a chief juſtice for civil and criminal affairs from whom an appeal may be made to the king; and under him are inferior officers in every town and community. Three offences, *viz.* treaſon, murder, and ſorcery, are deemed capital; and the two firſt are puniſhed with decollation, and the latter by being burned alive. The puniſhments of leſſer offences are the baſtonade, hanging, fines, and impriſonment.

The traffic of the Congoeſe with the Europeans conſiſts chiefly in ſlaves, and St. Salvadore is the principal mart of the country. The traders who reſide in this place bring thither the products of Braſil, ſuch as grain, fruit, plants, and other proviſions, and the manufactures of Europe, which are uſually Turkey carpets, Engliſh cloth, and other ſtuffs; copper and braſs veſſels, blue earthen ware, rings, and ornaments of gold, ſilver, and baſe metals, coral, glaſs beads, bugles, and other trinkets; tobacco, wine, brandy, and other ſpirituous liquors; light ſtuffs made of cotton, linen, and woollen, for cloathing; and a great variety of tools and utenſils. In return they carry off a number of ſlaves, amounting annually to 15 or 16,000. Slaves indeed are employed at home in all their laborious occupations, and are reckoned the moſt valuable commodities, which a man poſſeſſes or is able to bequeath to his children or relations. Among the Congoeſe every kind of manufacture is in a very imperfect ſtate. The roads through different parts indicate the inattention and indolence both of the government and the people, as they are either extremely bad in themſelves or infeſted with banditti, and a variety of pernicious animals.

The houſes of the Congoeſe are low, ill-built huts, thatched with ſtraw or fern, without windows and with doors ſo low, that the ſhorteſt man is obliged to ſtoop when he enters them. They are ſo ſlightly built, as to be liable to be blown away by a guſt of wind. Thoſe, however, belonging to the Portugueſe are built of brick and mortar, and generally well-furniſhed and adorned. The furniture of the Congoeſe houſes conſiſts chiefly of ſome few ill-contrived inſtruments for agriculture, a hatchet to fell timber, a cutlaſs for travelling or for war, ſome few calabaſhes for containing their proviſions, a pot, kettle, and ladle, a few earthen platters, and a hand-mill for grinding their corn. Their beſt bedding is a large coarſe ſackcloth, filled with ſtraw or leaves, with a ſlight covering, and perhaps a log of wood inſtead of a pillow. But the Portugueſe have introduced

troduced among the ſuperior claſſes, and particularly in the palaces of the princes and viceroys, various articles of luxury.

Polygamy was univerſally allowed in Congo before the introduction of Chriſtianity; and ſince that period, the miſſionaries have in vain endeavoured to perſuade the inhabitants to be contented, each of them, with one wife. Previous to marriage the perſon is allowed three years trial; and when this term is expired, the prieſt performs the ceremony, and the ſtipulated dowry is paid. This ceremony is preceded by a ſumptuous banquet, and dancing and drinking are continued till the next morning, when the parties retire.

The muſical inſtruments, now uſed by the Congoeſe, are ſuch as the Portugueſe have introduced; ſuch as the trumpet, cornet, French-horn, and fife; but the common people are contented with their fifes and tabors at their weddings and other rejoicings. They have alſo ſtringed inſtruments, which by their rude conſtruction ſeem to be natives of the country; ſuch are their "nſambi," reſembling the Spaniſh guitar, and the "marimba," conſiſting of fifteen or ſixteen ſmall calabaſhes, of different ſizes, faſtened to a flat board by ſtrings that paſs acroſs their mouths, and which, being touched by ſmall pieces of wood, like the ſticks of our dulcimers, yield an agreeable variety of ſounds. Their drums are made of a long hollow trunk of a tree, with a ſingle ſkin ſtretched over one end of it, the other being left open; they are beat either with the fiſts, or by ſticks of heavy wood, and are uſed at their feſtivals as well as in the army; they are called "ngambo" or "ingombo," and give but a dull heavy ſound, which is raiſed either by that of the fife, or the "longa," which conſiſts of two or more ſmall bells. The dancing of the Congoeſe conſiſts in a promiſcuous round of men and women, all ſtriving who ſhall ſhew the greateſt agility and variety of gambols, contortions, and indecent poſtures.

The hiſtory of the foundation of the monarchy of Congo is uncertain and fabulous. It is aſcribed to the ſon of a neighbouring prince, whoſe ſmall territory was ſituate on the banks of the Zair, in the province of Corimba. The name of the young prince was Luqueni, who ſubdued the whole province of "Npemlacaſſi," ſince called Congo, and extended his conqueſts from the mouth of the Zair to the city of St. Salvadore. His ſucceſſors, it is ſaid, have maintained themſelves on the throne ever ſince his time. This country was diſcovered by the Portugueſe in the reign of king John II., who employed Diego Cam, a perſon of enterpriſe and a famous navigator, in an expedition for making diſcoveries on the coaſts of Ethiopia. Cam, on his arrival near theſe coaſts in the year 1484, fell inſenſibly upon the rapid ſtream of the river Zair, as he was endeavouring to double the cape Catalina; and having caſt anchor at its mouth, he explored the country ſituated on its banks, and was well received by the inhabitants, who conducted four or five of his officers to St. Salvadore. Before their return, he determined to ſet ſail for Portugal, and took with him four of the natives. King John was ſo pleaſed with the account which he received of the country, that he ordered Cam to return with his companions as ſpeedily as poſſible, and furniſhed him with valuable preſents for the king and his court. He charged him, moreover, to exhort the monarch of Congo, in his name, to become a convert to the worſhip of the only true God, and to permit the Chriſtian religion to be propagated through his dominions. Cam, in the year 1485, arrived at Congo, and was very favourably received. No time was loſt in eſtabliſhing an alliance between the two crowns of Portugal and Congo, which has continued to ſubſiſt, though often ſuſpended by intervening wars. This alliance was followed by the converſion of the king to the Chriſtian faith. For a further account of the hereditary ſovereigns of Congo, too minute in detail to be introduced into our work, and too unintereſting at this remote period for abridgment, we refer to the "Modern Univerſal Hiſtory," vol. xiii.

Congo *money*, or *Guinea money*, a name given to a peculiar ſpecies of *concha veneris*, or porcelain-ſhell, which paſſes by way of money among the natives of thoſe places. It is diſtinguiſhed from the other porcelains by having a dentated mouth, and ſix gibbous protuberances on its ſurface.

Congo *Tea*, in *Commerce*. See Tea.

CONGORLAN, a town of Perſia, in the province of Irak; 75 miles N.N.E. of Amadan.

CONGOU, in *Geography*, a town of Perſia, ſituated on the eaſtern ſide of the Perſian Gulf. N. lat. 28°. E. long. 52°.

CONGRATULATION, denotes the immediate expreſſion of our joy, on account of any favourable event that has occurred in any of our connections.

CONGREGATION, an aſſembly of ſeveral eccleſiaſtics, united ſo as to conſtitute a body.

The term is principally uſed for aſſemblies of cardinals, appointed by the pope, and diſtributed into ſeveral chambers, for the diſcharge of certain functions and juriſdictions, after the manner of our offices and courts. The deciſions of theſe ſocieties are generally ſanctioned by the approbation of the Roman pontif, who has not a right, without alleging the moſt weighty and evident reaſons, to reverſe what they pronounce to be juſt and expedient. This form of eccleſiaſtical government is, without doubt, a check to the authority of the pope; and hence it is, that many things are tranſacted at Rome in a manner that is in direct oppoſition to the ſentiments of its ſpiritual ruler. This may ſerve to correct a miſtaken notion concerning the nature and limits of the papal hierarchy maintained by thoſe, who pretend, that all the iniquitous proceedings of the court of Rome, the calamities it has occaſioned, the contentions, rebellions, and tumults it has excited, are to be wholly laid to the charge of the Roman pontif. Hence alſo ariſes that important diſtinction that has been frequently employed by the French and other nations in their debates with the Roman pontif, that is, the diſtinction between "the pope of Rome," and "the court of Rome." The one is often loaded with the bittereſt reproaches and the heavieſt accuſations, while the other is ſpared, and in ſome meaſure excuſed. Nor is this diſtinction by any means groundleſs; ſince the cardinals and congregations, whoſe rights and privileges are held ſacred, undertake and execute many projects without the knowledge, and ſometimes againſt the will and conſent, of the Roman pontif.

The principal congregations of cardinals are theſe: 1. "The congregation of the Pope," inſtituted firſt by Sixtus V., to prepare the matters that were to be brought before the conſiſtory, at which the pope is always preſent. Hence this is called the "conſiſtorial congregation," and in it are treated all affairs relative to the creation of biſhops and cathedral churches, the reunion or ſuppreſſion of epiſcopal ſees, the alienation of church goods, and the taxes and annates that are impoſed upon all benefices in the pope's gift. The cardinal-dean preſides in this aſſembly. 2. "The congregation of the Inquiſition," or, as it is otherwiſe called, "of the holy office," inſtituted by Paul III., or, as others ſay, by Pius IV., and reformed by Pius VI., which takes cognizance of hereſies, apoſtacy, magic, and profane writings,

ings, aſſembling thrice in the week, and every Thurſday in preſence of the pope, who preſides in it. This congregation conſiſts of at leaſt 12 cardinals, with ſeveral other prelates and divines of different orders, who were called conſultors of the holy office. The office of grand inquiſitor, which encroached upon the prerogatives of the pontif, has been long ſuppreſſed, or rather diſtributed among the cardinals who belong to this congregation, and whoſe deciſions come under the ſupreme cognizance of his holineſs. See INQUISITION. 3. “The congregation for the propagation of the Roman Catholic faith,” founded under the pontificate of Gregory XV., and compoſed, (ſays the tranſlator of Moſheim's Eccl. Hiſt.), of 18 cardinals, one of the ſecretaries of ſtate, a prothonotary, a ſecretary of the inquiſition, and other inferior members. (See COLLEGE *de propaganda fide*). In this congregation are carried on the deliberations which relate to the extirpation of hereſy, the appointment of miſſionaries, &c.; this congregation has built a moſt beautiful and magnificent palace in one of the moſt agreeable ſituations that could be choſen at Rome, where proſelytes to popery from foreign countries are lodged and maintained gratis in a manner ſuitable to their rank and condition, and inſtructed in thoſe branches of knowledge to which their genius inclines. The prelates, vicars, and curates, who are obliged, without any fault on their own part, to abandon the places of their reſidence, are entertained charitably in this noble edifice, in a manner correſponding to their rank in the church. 4. “The congregation deſigned to explain the deciſions of the council of Trent.” 5. “The congregation of the Index,” whoſe principal buſineſs is to examine MSS. and books that are deſigned for publication, to decide whether the people may be permitted to read them, to correct thoſe books whoſe errors are not numerous, and which contain uſeful and ſalutary truths, to condemn thoſe whoſe principles are heretical and pernicious, and to grant the peculiar privilege of peruſing heretical books to certain perſons. This congregation, which is ſometimes held in the preſence of the pope, but generally in the palace of the cardinal-preſident, has a more extenſive juriſdiction than that of the inquiſition, as it not only takes cognizance of thoſe books that contain doctrines contrary to the Roman Catholic faith, but of thoſe alſo that concern the duties of morality, the diſcipline of the church, and the intereſts of ſociety. Its name is derived from the alphabetical tables, or indexes, of heretical books and authors, which have been compoſed by its appointment. 6. “The congregation for maintaining the rights and immunities of the clergy, and of the knights of Malta.” This congregation was formed by Urban VIII., to decide the diſputes and remove the difficulties and inconveniencies that aroſe from the trials of eccleſiaſtics before princes, or other lay-judges. 7. “The congregation relating to the Biſhops and regular Clergy,” inſtituted by Sixtus V., to decide the debates which ariſe between the biſhops and their dioceſans, and to compoſe the differences that happened ſo frequently among the Monaſtic orders. 8. “The congregation,” appointed by Gregory XIV., for examining into the capacity and learning of the biſhops. 9. “Another,” for inquiring into their lives and morals. 10. “A third,” for obliging them to reſide in their dioceſes, or to diſpenſe with that obligation. 11. “The congregation for ſuppreſſing monaſteries,” *i. e.* ſuch whoſe revenues are exhauſted, and which thereby become a charge upon the public. 12. “The congregation of the Apoſtolic Viſitation,” which names the viſitors who perform the duties and viſitations of the churches and convents within the diſtrict of Rome, to which the pope is obliged, as archbiſhop of that city. 13. “The congregation of Relics,” deſigned to examine the marks, and to augment the number of theſe inſtruments of ſuperſtition. 14. “The congregation of Indulgences,” deſigned to examine the caſe of thoſe who have recourſe to this method of quieting the conſcience. 15. “The congregation of Rites,” appointed by Sixtus V., to regulate and invent the religious ceremonies that are to be obſerved in the worſhip of each new ſaint that is added to the kalendar. Such are the congregations of cardinals, ſet apart for adminiſtering the ſpiritual affairs of the church; and they are undoubtedly, in ſome reſpects, a check upon the power of the pontif, enormous as it may be. There are ſix more, which relate to the temporal government of the papal territories. In theſe congregations, where the pope is never preſent, all things are tranſacted which relate to the execution of public juſtice in civil or criminal matters, the levying of taxes, the providing of good governors for the cities and provinces, the relief of thoſe who are unjuſtly oppreſſed by ſubordinate magiſtrates, the coinage, the care of the rivers, aqueducts, bridges, roads, churches, and public edifices.

CONGREGATION is alſo uſed for a company or ſociety of religious cantoned out of this or that order; and making, as it were, an inferior order, or a ſubdiviſion of the order itſelf. Such are the congregations of the Oratory, and thoſe of Cluny, &c. among the Benedictines.

The word is alſo uſed for aſſemblies of pious perſons, in manner of fraternities; frequent among the Jeſuits in honour of the Virgin, &c.

CONGREGATION *of Aids*, or *de Auxiliis*, was eſtabliſhed in conſequence of a diſpute between the Dominicans and Jeſuits. The former had long cheriſhed a deep rooted and invincible hatred againſt the latter; and having a favourable opportunity of venting their indignation, exhauſted their furious zeal againſt the doctrine of Molina, notwithſtanding the pacific orders of the papal edict, iſſued by Clement VIII., in the year 1594. They inceſſantly wearied the Spaniſh monarch, Philip II., and the Roman pontif, Clement VIII., with their importunate clamours, till at length the latter found himſelf under a neceſſity of aſſembling at Rome a ſort of council for the deciſion of this controverſy. Thus commenced, about the year 1598, thoſe famous deliberations concerning the conteſt of the Jeſuits and Dominicans, which were held in the congregation of aids. This congregation was ſo denominated on account of the principal point in debate, which was the efficacy of the aids and ſuccours of divine grace; and its conſultations were directed by Lewis Madruſi, biſhop of Trent, and one of the college of cardinals, who ſat as preſident in this aſſembly, which was compoſed beſides of three biſhops and ſeven divines, choſen out of ſo many different orders. The hiſtory and tranſactions of this congregation are related and illuſtrated by ſeveral writers of different complexions, by Jeſuits, Dominicans, and Janſeniſts. After all it is ſtill a matter of doubt, which party was moſt favoured by the court of Rome on this occaſion, the Jeſuits or the Dominicans, and which of theſe two parties defended their cauſe with the greateſt dexterity and ſucceſs.

CONGREGATION *of the Immaculate Conception*. See IMMACULATE.

CONGREGATION *of the Lateran*. See LATERAN.

CONGREGATION *of the Lord*, in *Eccleſiaſtical Hiſtory*, an aſſociation of reformers in Scotland, formed in the year 1557 by the earl of Argyle, his ſon lord Lorne, the earl of Morton and Glencarne, Erſkine of Dun, and others, who, obſerving the danger to which they were expoſed, and deſirous of propagating their principles, entered privately into a bond or aſſociation; and aſſumed this appellation

Strahan and Preſton,
New-ſtreet Square, London.

lation; in contradiſtinction to the eſtabliſhed church, which they denominated the congregation of Satan. Supported by the authority, which, they thought, belonged to them under the denomination they aſſumed, they ordained that prayer in the vulgar tongue ſhould be uſed in all the pariſh-churches of the kingdom; and that preaching, and the interpretation of the Scriptures, ſhould be practiſed in private houſes, till God ſhould move the prince to grant public preaching by faithful and true miniſters. This congregation, encouraged by ſome favourable appearances which occurred, proceeded with alacrity in openly ſoliciting ſubſcriptions to their league; and the death of Mary of England, with the acceſſion of Elizabeth, which happened about this time, contributed to increaſe their hopes of ultimate ſucceſs in their undertaking. They ventured to preſent a petition to the regent, craving a reformation in the church, and of the wicked, ſcandalous, and deteſtable lives of the prelates and eccleſiaſtics. They alſo framed a petition, which they intended to preſent to parliament, in which, after premiſing that they ſhould not communicate with the damnable idolatry, and intolerable abuſes of the papiſtical church, they deſired that the laws againſt heretics ſhould be executed by the civil magiſtrate alone, and that the Scripture ſhould be the ſole rule in judging of hereſy. They even petitioned the convocation, and inſiſted, that prayers ſhould be ſaid in the vulgar tongue, and that biſhops ſhould be choſen with the conſent of the gentry of the dioceſe, and prieſts with the conſent of the pariſhioners. The regent prudently temporized between theſe parties; but after ſome time, ſhe proceeded with greater rigour againſt the reformers, and the diſpute terminated in a civil war. At length the covenant was ſubſcribed by the reformers, who committed themſelves to the guidance of John Knox. The conſequence was, that the Catholic religion was ſuppreſſed, and the preſbyterian diſcipline eſtabliſhed. See REFORMATION.

CONGREGATION *of Miſſion.* See MISSION.

CONGREGATION *of Penitence.* See PENITENCE.

CONGREGATION *of Holy Sacrament.* See SACRAMENT.

CONGREGATION *of Holy Trinity.* See TRINITY.

CONGREGATION, in *Phyſics*, is uſed by Dr. Grew for the leaſt and loweſt degree of mixtion; or that wherein the parts of the mixt do not conſiſt with, or adhere to, each other, but only touch in one point. That author declares himſelf of opinion, that the particles of all *fluids* only touch in this manner; or that their coheſion only amounts to a *congregation*. See FLUID.

CONGREGATION alſo denotes an aſſembly of perſons in ſocial and public worſhip.

CONGREGATIONALISTS. See INDEPENDENTS.

CONGRESS, CONGRESSUS, is uſed for an aſſembly of commiſſioners, deputies, envoys, &c. from ſeveral courts or provinces, meeting to ſettle terms for a general pacification or to concert meaſures for their common good.

The congreſs at the Hague, while held during the courſe of the war, terminated in 1697, by the treaty of Ryſwick, was compoſed of the envoys of all the princes in the confederacy againſt France.

CONGRESS, in *Modern Hiſtory*, denotes that body, in which, by the conſtitution of the United States of America, all legiſlative powers are veſted. It conſiſts of a ſenate and houſe of repreſentatives. The houſe of repreſentatives is compoſed of members choſen every ſecond year by the people of the ſeveral ſtates; and the electors in each ſtate ſhall have the qualifications requiſite for electors of the moſt numerous branch of the ſtate legiſlature. No perſon ſhall be a repreſentative under the age of 25 years, who has not been ſeven years a citizen of the United States, and who ſhall not, when elected, be an inhabitant of the ſtate in which he ſhall be choſen. The number of repreſentatives, apportioned among the ſeveral ſtates, which may be included within this union, according to their reſpective numbers, to be aſcertained by actual enumeration within three years after the firſt meeting of congreſs, and within every ſubſequent term of ten years, ſhall not exceed one for every thirty thouſand; but each ſtate ſhall have at leaſt one repreſentative. In caſe of vacancy in the repreſentation of any ſtate, writs ſhall be iſſued by the executive authority for filling ſuch vacancies. The houſe of repreſentatives chuſe their ſpeaker, and other officers, and have the ſole power of impeachment.

The ſenate of the United States is compoſed of two ſenators from each ſtate, choſen by its legiſlature for ſix years; and each ſenator has one vote. The ſenators are divided into three claſſes; the ſeats of thoſe of the firſt claſs being vacated at the expiration of the ſecond year; of the ſecond claſs at the expiration of the fourth year; and of the third claſs at the expiration of the ſixth year; ſo that one-third may be choſen every ſecond year.

No perſon ſhall be a ſenator, under the age of 30 years; after being nine years a citizen of the United States, and who is not, when elected, an inhabitant of the ſtate for which he is choſen. The vice-preſident of the United States is preſident of the Senate, but has no vote, unleſs the votes be equally divided. The ſenate chuſes its other officers, and alſo a preſident pro tempore, in the abſence of the vice-preſident, or when he ſhall exerciſe the office of preſident of the United States. The ſenate has the ſole power to try all impeachments; and no perſon ſhall be convicted without the concurrence of two-thirds of the members preſent.

The congreſs ſhall aſſemble at leaſt once in every year, and ſuch meeting ſhall be on the firſt Monday in December, unleſs they ſhall, by law, appoint a different day. Each houſe has its peculiar powers; but neither houſe, during the ſeſſion of congreſs, ſhall, without the conſent of the other, adjourn for more than three days, nor to any other place than that in which the two houſes ſhall be ſitting. The ſenators and repreſentatives ſhall receive a compenſation for their ſervices, aſcertainable by law, and payable out of the treaſury of the United States. They are, in all caſes, except treaſon, felony, and breach of the peace, privileged from arreſt during their attendance at the ſeſſion of their reſpective houſes, and in going to, and returning from, them; and for any ſpeech or debate in either houſe, they are not to be queſtioned in any other place. No ſenator or repreſentative ſhall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which ſhall have been created, or the emoluments of which ſhall have been increaſed, during ſuch time; and no perſon holding any office under the United States ſhall be a member of either houſe, during his continuance in office.

All bills for raiſing revenue ſhall originate in the houſe of repreſentatives; but the ſenate may propoſe or concur with amendments, as on other bills. Every bill, which ſhall have paſſed the houſe of repreſentatives, and the ſenate, ſhall, before it become a law, be preſented to the preſident of the United States; if he approve, he ſhall ſign it; but if not, he ſhall return it, with his objections, to that houſe in which it has originated, who, having entered the objections on their journal, ſhall proceed to reconſider it. If, after reconſideration, two-thirds of that houſe ſhall agree to paſs the bill, it ſhall be ſent, together with the objections, to the other houſe, by which it ſhall likewiſe be reconſidered, and, if approved by two-thirds of that houſe, it ſhall become a law. In ſuch caſe the votes of both houſes ſhall be determined by yeas and nays, and the names of the perſons voting for and againſt the bill ſhall be entered on the journal of each houſe, reſpectively. If any bill ſhall not be returned by the preſident within ten days (Sundays excepted) after it has been preſented to him, the ſame ſhall be a law, as if he had ſigned it, unleſs the congreſs, by their adjournment, prevent its return, in which caſe it ſhall not be a law. Every order, reſolution, or vote, to which the concurrence of the ſenate and houſe of repreſentatives may be neceſſary, ſhall be ſubject to the ſame rules and limitations as are preſcribed in the caſe of a bill.

By the conſtitution the congreſs ſhall have power—to lay and collect taxes, duties, impoſts, and exciſes—to pay the debts and provide for the common defence and general welfare of the United States—to borrow money on the credit of the United States—to regulate commerce with foreign nations, among the ſeveral ſtates, and with the Indian tribes—to eſtabliſh an uniform rule of naturalization, and uniform laws on the ſubject of bankruptcies, throughout the United States—to coin money, regulate its value, and that of foreign coin, and to fix the ſtandard of weights and meaſures—to provide for the puniſhment of counterfeiting the ſecurities and current coin of the United States—to eſtabliſh poſt offices and poſt-roads—to promote the progreſs of ſcience and uſeful arts, by ſecuring for limited times, to authors, and inventors, the excluſive right to their reſpective writings and diſcoveries—to conſtitute tribunals inferior to the ſupreme court—to define and puniſh piracies and felonies committed on the high ſeas, and offences againſt the law of nations—to declare war, grant letters of marque and repriſal, and make rules concerning captures on land and water—to raiſe and ſupport armies, but without appropriating money to that uſe for a longer term than two years—to provide and maintain a navy—to make rules for the government and regulation of the land and naval forces—to provide for calling forth the militia to execute the laws of the Union, ſuppreſs inſurrections, and repel invaſions—to provide for organizing, arming, and diſciplining the militia, &c. reſerving to the ſtates, reſpectively, the appointment of the officers, and the authority of training the militia, according to the diſcipline preſcribed by congreſs—to exerciſe excluſive legiſlation, in all caſes whatſoever over ſuch diſtrict, (not exceeding ten miles ſquare) as may, by ceſſion of particular ſtates, and the acceptance of congreſs, become the ſeat of the government of the United States, and to exerciſe like authority over all places, purchaſed by conſent of the legiſlature of the ſtate in which the ſame ſhall be, for the erection of forts, magazines, arſenals, dock-yards, and other needful buildings—and to make all laws which ſhall be neceſſary and proper for carrying into execution the foregoing powers, and all other powers veſted by this conſtitution in the government of the United States, or in any department or officer thereof.

The powers of congreſs, however, are ſubject to certain limitations; *e. g.* the privilege of the writ of habeas corpus ſhall not be ſuſpended, unleſs the public ſafety requires it in caſes of rebellion or invaſion. No bill of attainder, or ex poſt facto law, ſhall be paſſed. No capitation, or other direct tax, ſhall be levied, unleſs in proportion to the cenſus, or enumeration, herein before directed to be taken.—No tax or duty ſhall be laid on articles exported from any ſtate—no preference ſhall be given by any regulation of commerce or revenue, to the ports of one ſtate over thoſe of another—nor ſhall veſſels bound to or from one ſtate be obliged to enter, clear, or pay duties, in another—no money ſhall be drawn from the treaſury, but in conſequence of appropriations made by law; and a regular ſtatement and account of the receipts and expenditures of all public money ſhall be publiſhed from time to time. No title of nobility ſhall be granted by the United States; and no perſon holding any office of profit or truſt under them ſhall, without the conſent of the congreſs, accept of any preſent, emolument, office, or title, of any kind whatever, from any king, prince, or foreign ſtate. With regard to individual ſtates it is provided, that no ſtate ſhall enter into any treaty, alliance, or confederation; grant letters of marque and repriſal; coin money; emit bills of credit; make any thing but gold and ſilver coin a tender in payment of debts; paſs any bill of attainder, ex poſt facto law, or law impairing the obligation of contracts; or grant any title of nobility. Moreover, no ſtate ſhall, without the conſent of the congreſs, lay any impoſts or duties on imports or exports, except what may be abſolutely neceſſary for executing its inſpection laws; and the net produce of all duties and impoſts, laid by any ſtate on imports or exports, ſhall be for the uſe of the treaſury of the United States; and all ſuch laws ſhall be ſubject to the reviſion and control of the congreſs. No ſtate ſhall, without the conſent of congreſs, lay any duty of tonnage, keep troops or ſhips of war in time of peace, enter into any agreement or compact with another ſtate, or with a foreign power, or engage in war, unleſs actually invaded, or in ſuch imminent danger as will not admit of delay. The congreſs, under certain limitations, whenever two-thirds of both houſes ſhall deem it neceſſary, may propoſe amendments to the conſtitution, eſtabliſhed Sept. 17, 1787; or, on the application of the legiſlature of two-thirds of the ſeveral ſtates, ſhall call a convention for propoſing amendments, which, in either caſe, ſhall be valid, to all intents and purpoſes, as part of the conſtitution, when ratified by the legiſlatures of three-fourths of the ſeveral ſtates, or by conventions in three-fourths thereof, as the one or the other mode of ratification may be propoſed by the congreſs. The ſenators and repreſentatives before-mentioned, and the members of the ſeveral ſtate legiſlatures, and all executive and judicial officers, both of the United States, and of the ſeveral ſtates, ſhall be bound by oath or affirmation, to ſupport the conſtitution; but no religious teſt ſhall ever be required as a qualification to any office, or public truſt, under the United States. The executive power is veſted by the conſtitution in a preſident of the United States of America. See PRESIDENT.

CONGRESS, in *Law*, is alſo uſed for an eſſay, or trial, made by appointment of a lay, or ſpiritual judge, in the preſence of ſurgeons and matrons, to prove, whether or no a man be or be not impotent; in order to the diſſolution of a marriage. See IMPOTENCE.

Neither the civil nor canon law make any mention of this trial of virility by congreſs; it had its origin in France, from the boldneſs of a young fellow, who, in open court, being hard preſſed by his wife, demanded the congreſs. The judge, ſurpriſed with the novelty of the demand, found it could not be denied; as being the ſureſt evidence the caſe could admit of.

In time it became a branch in the French juriſprudence, and was authorized by decrees and arrets: it obtained for about the ſpace of one hundred and twenty years, and was annulled by an arret of parliament in 1677, as being found precarious; ſome having failed under the experiment out of mere modeſty and ſhame, which is found to have the ſame effect with actual impotency.

CONGREVE,

CONGREVE, William, in *Biography*, a celebrated Engliſh dramatic writer, deſcended from an ancient family in Staffordſhire, which traces its lineage beyond the Norman conqueſt. Neither the time nor the place of his birth can be aſcertained with any degree of preciſion; according to the inſcription on his monument, it was in the year 1672, and he himſelf declares that he owed his nativity to England; though by many of his biographers it has been aſſerted that he was born in Ireland. Wherever he was born, it is known that he was educated, firſt at Kilkenny, and afterwards at Dublin, his father having ſome military employment that ſtationed him in Ireland. After he had paſſed the uſual preparatory ſtudies, he was ſent, at the age of ſixteen, to ſtudy the law in the Middle Temple. For this his genius does not appear to have been adapted: he looked, at a very early period of life, to polite literature as that by which he might be diſtinguiſhed. By a feigned name he publiſhed the "Incognita, or Love and Duty reconciled," a novel, which has been characterized as ſprightly in dialogue, intricate in plot, and unnatural; and Dr. Johnſon ſays "he would rather praiſe than read it." As a dramatic writer, Congreve's firſt piece was the "Old Bachelor," written at the age of twenty, and, according to the author's own account, to amuſe himſelf in a ſlow recovery from a fit of ſickneſs; but which was regarded by Dryden, and others who were his contemporaries, as a very wonderful performance. Its ſucceſs was very great; few plays have been ſo beneficial to the writer, for it procured him the patronage of the earl of Halifax, who was the Mæcenas of the day, and who deſerves the praiſe of having beſtowed more public patronage on the muſes than they have ever received before, or perhaps ſince, in this country. Upon Congreve the noble lord beſtowed the office of commiſſioner for licenſing coaches; and ſoon after gave him a place in the pipe-office, and another in the cuſtoms of 600*l.* per annum.

If the Old Bachelor be nearly examined, ſays Dr. Johnſon, "it will be found to be one of thoſe comedies which may be made by a mind vigorous and acute, and furniſhed with comic characters by the peruſal of other poets, without much actual commerce with mankind. The dialogue is one conſtant reciprocation of conceits, or claſh of wit, in which nothing flows neceſſarily from the occaſion, or is dictated by nature. The characters both of men and women are either fictitious or artificial; and the cataſtrophe ariſes from a miſtake not very probably produced, by marrying a woman in a maſk. Yet this gay comedy, when all theſe deductions are made, will ſtill remain the work of very powerful and fertile faculties; the dialogue is quick and ſparkling, the incidents ſuch as ſeize the attention, and the wit ſo exuberant that, it "o'er-informs its tenement."

Congreve's next play was "The Double Dealer," which was not received with equal kindneſs by the public, but which was honoured with the patronage of the queen, on whoſe death he wrote a poetical tribute to her memory; in which, ſays his biographer, "all is unnatural, and yet nothing is new." In the year 1695, his prolific pen produced "Love for Love," a comedy of nearer alliance to life, and exhibiting more real manners, than either of the former. This proved a very popular and profitable piece: and in the ſame year he publiſhed an irregular ode to king William, on the taking of Namur; which exhibited leſs of the powers of poetry, than of the ſpirit of loyalty. With the comedy of Love for Love, the new theatre was opened, under the direction of Betterton the tragedian; where, in 1697, was exhibited "The Mourning Bride," a tragedy, ſo written, as to ſhew that the author was ſufficiently qualified for either kind of dramatic poetry.

About this time began a long and bitter controverſy between Jeremy Collier and the poets. In the reign of Charles I., the puritans had raiſed a violent clamour againſt the drama, which they regarded as unfit for the encouragement of Chriſtians. This had in a great meaſure ſubſided, when, in 1698, Collier publiſhed "A Short View of the Immorality and Profaneneſs of the Engliſh Stage;" in which he attacked with great juſtice, though perhaps with ſome degree of aggravation, the licentiouſneſs of the dramatic writers, among whom Congreve was included. The poet replied, and endeavoured to palliate the alleged enormity of particular paſſages, though it was impoſſible to vindicate the general character and tendency of his pieces. Collier replied, and Congreve retired from the conteſt; and ſhortly after publiſhed his laſt comedy of "The Way of the World." This was reckoned the moſt perfect of his dramatic pieces; but it was received with ſo little favour on the ſtage, that, being in a high degree offended and diſguſted, he reſolved to commit his quiet and his fame no more to the caprices of an audience. From this time his life ceaſed to the public; he lived for himſelf and for his friends; and among his friends he was able to name every man of his time whom wit and elegance had raiſed to reputation.

Congreve continued to write copies of verſe upon particular occaſions, and in the year 1710, he publiſhed a collection of his plays and miſcellaneous poems, dedicated to his patron lord Halifax, to whoſe perſon and party he remained attached in all fortunes. Such was the reſpect which Congreve inſpired, as well by his private character as his genius, that in the great political change which brought the tories into power, his places were untouched, and he was allowed to maintain a dignified neutrality, praiſed and complimented on both ſides. On the return of his own friends to power, his emoluments were increaſed by the ſinecure place of ſecretary to the iſland of Jamaica, which raiſed his public income to full 1200*l.* a year: yet, ſays Dr. Johnſon, his honours were far greater than his profits. Every writer mentioned him with reſpect; and, among other teſtimonies to his merit, Steele made him the patron of his "Miſcellany," and Pope inſcribed to him his tranſlation of the Iliad.

Indolence was the reſult of Congreve's affluence. He not only ceaſed to make any literary exertions, but ſeems, with a conſiderable degree of affectation, to have declined the character of a man of letters; and when he received a viſit from Voltaire, the topic of his writings being introduced, Congreve ſpoke of them as trifles beneath him, and hinted that he expected to be viſited only as a gentleman. Voltaire replied, that had Mr. Congreve been ſo unfortunate as to be a mere gentleman, he ſhould never have been deſirous of ſeeing him.

The latter years of his life were clouded with a conſiderable portion of ſickneſs and infirmity. Cataracts in his eyes at length terminated in total blindneſs. The melancholy ſtate was aggravated by the gout, for which he ſought relief by a journey to Bath, but, being overturned in his chariot, he returned to his houſe in London, where he died, Jan. 29, 1728-9, in the ſixtieth year of his age. Having lain in ſtate in the Jeruſalem chamber, he was buried in Weſtminſter Abbey, where a monument is erected to his memory by the ducheſs of Marlborough; to whom, for reaſons either not known, or not mentioned, he bequeathed a legacy of ten thouſand pounds, in preference to the claims of kindred, at that time reduced to difficulties and diſtreſs.

It does not appear that any peculiar moral excellencies, or any remarkable talents for ſocial intercourſe, obtained for Congreve thoſe marks of attachment and regard which we have ſeen that he enjoyed. He lived in an eaſy independence, and, by the exerciſe of a poliſhed good nature, pleaſed and flattered thoſe who aſſociated with him, and never offended any one. He ſtands firſt among the Engliſh writers of comedy: a diſtinction for which he is indebted, not to ſuch a lively and humorous delineation of natural characters as delights and inſtructs in the ſcenes of Moliere, but to a continuation of wit and repartee in the dialogue, joined with originality of plot. His perſonages are always ſtrongly marked and well ſupported. One or two of his comedies are ſtill exhibited, and beheld with pleaſure, though ſo little reſembling the productions of the preſent age. His "Mourning Bride" is intereſting, and its principal characters well contraſted; it maintains its place in our theatres, and has, during the preſent ſeaſon, been repreſented with the higheſt applauſe. Biogr. Britan. Johnſon's Lives of the Engliſh Poets.

CONGRIER *en Pouance*, in *Geography*, a town of France, in the department of the Mayenne; 6½ leagues S.W. of Laval.

CONGRUITY, or CONGRUENCY, in the *Schools*, a ſuitableneſs or relation of agreement between things; whereby we come at the knowledge of what may be expected from them.

The ſyſtem of congruity in matters of grace conſiſts in this; that God, who knows perfectly the nature of grace, and the diſpoſitions of the will in all the circumſtances that ſhall befall a man, gives graces, wherewith, by virtue of their congruity with the will of a man, conſidered in thoſe circumſtances, man will always infallibly, but not neceſſarily, do what God would have him do; becauſe the will, in the language of the congruiſts, does always infallibly, though voluntarily, chooſe what appears beſt.

CONGRUITY, *merit of.* See MERIT.

CONGRUITY, in *Geometry*, is applied to figures, lines, &c. which exactly correſpond when laid over one another; as having the ſame terms, or bounds.

Thoſe things between which there is a congruity are equal and ſimilar.

Euclid, and by his example, moſt other geometricians, demonſtrate all their elements from the ſole principle of congruity: M. Leibnitz, and after him Wolfius, ſubſtitute the notion of ſimilitude in lieu of that of congruity.

CONGRUITY, in a lax ſenſe, is uſed to expreſs an aptitude, in ſome bodies, to unite, or incorporate; by reaſon of ſome ſimilitude or fitneſs of their figures: as incongruity denotes an unfitneſs of their ſurfaces for joining together. Thus, quickſilver will unite with gold, and many other metals, but will roll off from wood, ſtone, glaſs, &c.; and water, which will wet ſalt, and diſſolve it, will ſlip off from tallow without adhering to it; as alſo from a duſty ſurface, and from the feathers of water fowl.

Two drops of water or of mercury, will, on contact, immediately join and coaleſce; but oil of tartar, poured upon quickſilver, and ſpirit of wine and oil of turpentine on that, and air over all, will remain in the ſame veſſel without any manner of union, or mixture with each other. And the cauſe of this phenomenon is, that the figures of ſome bodies will not admit other bodies near enough to be within their ſpheres of attraction, whence they cannot join and cohere; but where their fitneſs of figure will let them approach near enough to feel each others' attractive power, then they cloſe and hold together. See COHESION.

CONG-TCHIN, in *Geography*, a town of China, of the third rank, in the province of Quang-ſi; 20 miles N.E. of Ping-lo.

CONGUSTUS, in *Ancient Geography*, a town of Aſia, in Galatia. Ptolemy.

CONHOCTON CREEK, in *Geography*, a creek of America, in the weſtern parts of the ſtate of New York, in the Geneſee country, which runs over a bed of gravel at the foot of the hills that ſurround the newly eſtabliſhed poſt-town, called Bath, and, about 20 miles below this town, falls into Tyoga river. In this creek there is a conſiderable fall, juſt above the town, which affords a very fine ſeat for mills. Extenſive ſaw and flour mills have already been erected upon it; the principal ſaw in the former of which, gave, when Mr. Weld viſited the mill, 120 ſtrokes in a minute, ſufficient to cut, in the ſame interval of time, 7 ſquare feet, ſuperficial meaſure, of oak timber; and yet capable, when the water is high, of producing effect much more expeditiouſly. During floods, light batteaux may paſs along the creek, Tyoga and Suſquehannah rivers, from Bath to Cheſapeak bay, without interruption.

CONI, a large fortified town of France, in the department of Stura, which was formerly a part of Piedmont in Italy, belonging to the king of Sardinia. It is ſituated on the confluence of the Geſſe and the Stura, 42 miles S. from Turin, 54 N.E. from Nice, and 615, or 820 kiliometres, from Paris. As chief place of the department, it has a prefect, a court of juſtice, and ſeveral tax offices, and is the reſidence of the brigade-general commanding the department. The fertility of the ſoil of its diſtrict, equally abundant in corn and paſtures, and the advantage of a canal which goes from the river Stura to the Po, and facilitates its communication with the interior parts of France, render Coni the centre of a conſiderable commerce. Its inhabitants amount to 16500. The population of the canton, including 16 communes, is 17,275. The whole diſtrict comprizes 85 communes with 121,433 inhabitants, upon a territorial extent of 2530 kiliometres.

Coni is ſaid to have been firſt founded in 1520, during the pontificate of Calixtus II.; and the following account is given of its origin. The inhabitants of ſome villages having been grievouſly oppreſſed by their lords, who, among other enormities, pretended a privilege granted by the emperor to deflower the brides before the huſbands touched them, the people, at length, attacked their lords, expelled them the country, and deſtroyed their caſtles, which had ſerved as their protection, and leſt their oppreſſors ſhould return with foreign aid, they left their home and founded Coni. Their number daily increaſing, they formed an alliance with the city of Aſti, and Luchin, duke of Milan, and became a flouriſhing republic, which form of government continued for ſome years. At length they ſubmitted to Charles of Anjou, comte of Provence. Some time after his death, they came under Jane, queen of Naples, who was incapable of ſupporting the weight of government; and therefore the town of Coni, in order to enſure protection, voluntarily ſubmitted to Amadeus VI., comte of Savoy, to whom it afterwards continued faithful. After valiantly defending itſelf againſt many ſucceſſive ſieges, for near three centuries, the rapid ſucceſſes of the French in Piedmont, during the months of April and May in 1796, obliged the king of Sardinia to make overtures for peace, and to ſurrender Coni, with Alexandria, Suſa, and Tortona, into the hands of the French, as hoſtages of his good faith; and it afterwards became the principal place of a diſtrict, as we have already ſtated, in one of the ſix Piedmonteſe departments, called Stura.

CONIA, in *Botany*, the name of a genus formed by Ventenat, for the powdery byſſi of Linnæus and other authors.

CONIACI, in *Ancient Geography*, a people of Spain, placed by Strabo near the ſources of the Ebrus, in the vicinity of the Cantabri.

CONIC SECTIONS, as the name imports, are ſuch curvelines as are produced by the mutual interſection of a plane and the ſurface of a ſolid cone. The nature and properties of theſe figures were the ſubject of an extenſive branch of the *Ancient Geometry*, and formed a ſpeculation well ſuited to the ſubtle genius of the Greeks. In modern times, the conic geometry is intimately connected with every part of the higher mathematics and natural philoſophy. A knowledge of thoſe diſcoveries, that do the greateſt honour to the laſt and the preſent centuries, cannot be attained without a familiar acquaintance with the figures that are now to engage our attention.

In this article we ſhall treat of the cone, and the more general properties of thoſe figures called the conic ſections; and we ſhall conclude with a ſhort hiſtorical account of this branch of mathematical learning. The more particular properties of each figure will be delivered under the proper heads in the progreſs of our work.

We begin with premiſing a few lemmas, on which the theory of conic ſections, we are to deliver, is founded.

LEMMAS.

Definition. If a right line, A B (*Plate* II. *Conics: fig.* 1.), be ſo divided in the points D and E, that A D is to D B as A E is to E B; then that right line is ſaid to be harmonically divided.

Cor. If a right line, A B, be divided in E, then it cannot be cut in D and *d*, ſo as to be harmonically divided both in E and D, and in E and *d*.

For, if it were poſſible, it is plain that A D would be to D B as A *d* to *d* B, 11. 5. E: which is abſurd, 14. 5. E.

LEMMA I. *Fig.* 1.

If a right line, A B, be biſected in C, and cut in E and D, ſo that C A or C B is a mean proportional between C E and C D: then A B is harmonically divided in D and E.

For, becauſe $CD : CA :: CA : CE$
therefore, $CD + CA : CD - CA :: CA + CE : CA - CE$
that is, $AD : DB :: AE : EB$.

Cor. If A B be biſected in C, and harmonically divided in D and E, then A C or C B is a mean proportional between C D and C E. *Cor. Def.* 1.

LEMMA II. *Fig.* 2.

If two tangents of a circle be drawn from the ſame point, A, then any chord of the circle, as E D, which, being produced, paſſes through A, and cuts the line, B C, that joins the two points of contact, in F, is harmonically divided in the points F and A.

Let O be the centre of the circle, and draw O H perpendicular to E D, and draw O B and O C to the points of contact. Becauſe the angles at B, H, and C, are all right angles, 18. 3. E, the circle deſcribed on the diameter A O will paſs through A, B, H, O, and C, 31. 3. E: therefore $AF \times FH = BF \times FC = EF \times FD$, 35. 3. E: therefore $AF \times FH + FH^2$, or $AH \times FH = EF \times FD + FH^2 =$ (becauſe E D is biſected in H) HD^2, 5. 2. E. Therefore E D is harmonically divided in F and A, *Lem.* 1.

Cor. And if a chord, as E D, which, when produced, paſſes through A, be harmonically divided in A and F, then F is a point in the chord B C.

For, if not, then the chord, D E, could be harmonically divided at A and F, and alſo at A, and another point, different from F, which is abſurd. *Cor. Def.*

LEMMA III. *Fig.* 3 and 4.

Let C be the centre of a circle, and let D and E be two points in a diameter, A B, and both on the ſame ſide of the centre; and let the radius of the circle be a mean proportional between C D and C E: draw M N perpendicular to A B through E; then any chord, as H K, which, being produced if neceſſary, paſſes through D, and cuts M N in F, is harmonically divided in D and F.

Draw C L perpendicular to H K from the centre C. Becauſe $CA^2 = CD \times DE$, therefore $CA^2 - CD^2$ (or $CD^2 - CA^2$), or $AD \times DB = EC \times CD - CD^2$ (or $CD^2 - EC \times CD$), or $CD \times DE$. And becauſe the angles at E and L are right angles, therefore $LD \times DF = CD \times DE = AD \times DB = HD \times DK$, 35. 3. E. $=$ (becauſe H K is biſected in L), $LK^2 - DL^2$ (or $DL^2 - LK^2$). Therefore, $LK^2 = DL^2 + LD \times DF$ (or $DL^2 - LD \times DF$) $= DL \times LF$: therefore H K is harmonically divided in D and F. *Lem.* 1.

LEMMA IV. *Fig.* 5 and 6.

The ſame conſtruction being made as in the laſt lemma; if H K be a chord, which, when produced if neceſſary, paſſes through D; then tangents of the circle drawn from the extremities of H K will meet one another in the line M N. And if tangents of the circle be drawn from a point aſſumed in M N, the chord drawn through the two points of contact, being produced if neceſſary, will paſs through the point D.

Let H K be a chord paſſing through D, and let tangents drawn from H and K meet in F: draw C F (cutting H K in L) to the centre of the circle, and join C K and F E. It is manifeſt that $FC \times CL = CK^2$, 8. 6. E. $= CD \times CE$, hyp. Therefore a circle deſcribed through D, F, and L, will paſs through E, 36. 3. E; therefore the angle $FED =$ the angle FLD, 21. 1. E. Therefore F E is perpendicular to A B, and F is a point in M N drawn from E perpendicular to A B.

Next, let F be in M N, and let H K and A B, both produced if neceſſary, interſect in *d*. Becauſe the angles F L *d* and F E *d* are right angles; therefore $FC \times CL = dC \times CE$, 36. 3. E. But $FC \times CL = CK^2 = CD \times DE$; therefore $dC \times CE = DC \times CE$; therefore the point *d*, in which H K and A B interſect, is the ſame as the point D.

LEMMA V. *Fig.* 7.

If the baſe of a triangle, A B, be biſected in D, and C G be drawn parallel to A B through the vertex; then any line, as E F, parallel to C D, and terminated by C B and C A, produced if neceſſary, is biſected by C G.

Draw B H K parallel to C D. Becauſe $AD = DB$; therefore $AC = CK$, 2. 6. E. Therefore $BH = HK$. And, it is plain that E F, parallel to B K, is likewiſe biſected.

LEMMA VI. *Fig.* 8 and 9.

If A B, the baſe of a triangle, be harmonically divided in D and E, and the lines C D and C E be drawn; then any line, as H F, parallel to C E, and terminated by B C and C A, produced if neceſſary, is biſected by C D.

Draw L K parallel to C E through D.
Becauſe $AD : DB :: AE : EB$.
Alternando, $AD : AE :: DB : EB$.
But, on account of equiangular triangles,
$AD : AE :: DL : CE$, 4. 6. E.
and $DB : BE :: DK : CE$;
therefore $DL : CE :: DK : CE$.

Therefore D L = D K, 9. 5. E. Therefore any line parallel to L K, as F H, is biſected by C D.

Cor. If H F be biſected by C D, and C E be parallel to H F, then A B is harmonically divided in D and E.

For, if not, then H F could be biſected by two lines drawn through C; which is abſurd.

Of the Cone and its Sections.

Definitions.

Fig. 10. I. Let A D B be a circle, and V a fixed point without the plane of the circle; then, if a right line, paſſing continually through the point V, be carried round the whole periphery of the circle A D B, that right line, being extended indefinitely on the ſame ſide of V as the circle, will deſcribe a conic ſurface; and, if it be likewiſe extended indefinitely on the other ſide of V, it will deſcribe two oppoſite conic ſurfaces.

Cor. A ſtraight line drawn from the vertex to any point in a conic ſurface, being produced indefinitely, is wholly in the oppoſite ſurfaces.

For a line, ſo drawn, will coincide with the line that generates the conic ſurfaces, when this line, by being carried round the circumference of the baſe, comes to the propoſed point.

II. The ſolid figure, contained by the conic ſurface and the circle A D B, is called a cone. The point V is named the vertex of the cone; the line V C, drawn to the centre of the circle, the axis of the cone; and the circle A D B, the baſe of the cone.

III. A right cone is when the axis is perpendicular to the plane of the baſe; otherwiſe, it is a ſcalene, or oblique cone.

IV. A right line that meets a conic ſurface in one point only, and is every where elſe without that ſurface, is called a tangent.

Prop. I. *Fig.* 10.

The common interſection of a conic ſurface and a plane V D E, that paſſes through the vertex, and cuts the baſe of the cone, is a rectilineal triangle.

For the common ſection of the plane of the baſe, and the plane drawn through the vertex, (which is a right line, 3. 11. E.), will cut the periphery of the baſe in two points, D and E, and in theſe two points only: then, having drawn D V and E V to the vertex of the cone, theſe lines will be both in the conic ſurface (*Cor. Def.* 1.), and alſo in the plane ſurface; and there are no points, excepting in theſe lines indefinitely produced, which are common to both the ſurfaces. Therefore the figure D V E, which is the common interſection of the cone and a plane through the vertex, is a rectilineal triangle.

Prop. II. *Fig.* 11 and 12.

If two points, D and E, (not in the ſame right line with the vertex) be aſſumed in a conic ſurface, the right line that joins them falls wholly within the conic ſurface, and when produced both ways it falls wholly without the ſurface; but if the aſſumed points be in oppoſite ſurfaces, the right line that joins them falls without the conic ſurfaces, and, when produced, it falls within one conic ſurface on one ſide, and within the other conic ſurface on the other ſide.

From V, the vertex of the cone, draw the lines V D and V E, cutting the periphery of the baſe in the points B and C; then, a plane being drawn through the vertex and the points D and E, that plane will cut the baſe in the chord B C, and the common ſections of the plane and the conic ſurfaces are the two right lines V B and V C indefinitely produced, *Pr.* 1. Now the right line D E, which is wholly contained in this plane, can meet the lines V B and V C only in the points D and E. When the points D and E are in the ſame conic ſurface, then the line D E is contained in the angle B V C within the conic ſurface, and, produced both ways, it is contained in the adjacent angles B V M and C V N without the conic ſurface. On the other hand, when D and E are in oppoſite ſurfaces, D E is contained in the angle B V M, or C V N, without the conic ſurfaces, and, being produced both ways, it is contained either in the angle B V C, or in the angle M V N, within the conic ſurfaces.

Cor. A right line cannot meet a conic ſurface in more than two points.

Prop. III. *Fig.* 11.

If a point, E, be aſſumed in a conic ſurface, and a line, P Q, be drawn through it, ſo as to be parallel to a right line, V B, paſſing through the vertex, and contained in the conic ſurfaces; then the right line, P Q, will not meet either of the oppoſite ſurfaces in another point, but it will fall within the ſurface, in which the aſſumed point E is, on the one ſide, and it will be wholly without both ſurfaces on the other ſide.

For if a plane be conceived to be drawn through the line V B and the point E, the line P Q, parallel to V B, will be wholly in that plane, 7. 11. E; and the common ſections of the plane and the conic ſurfaces will be the line V B and the line V E C drawn through the vertex and the point E, *Pr.* 1. Now the line, Q P, does not meet either of the lines V B or V C in another point different from E. Alſo Q E, the part of the line that is contained in the angle B V C, is within the cone; and P E, the part of it that is contained in the angle C V N, is without both the oppoſite ſurfaces.

Prop. IV. *Fig.* 12.

If a plane be drawn through the vertex of a cone and a tangent of the conic ſurface G H, it will meet the conic ſurface only in the line, V D, drawn through the vertex of the cone and the point of contact of the tangent.

For, becauſe the point D and the vertex V are common both to the plane ſurface and to the conic ſurface, therefore the line V D, indefinitely produced, is likewiſe common to both ſurfaces. And becauſe G H meets the conic ſurface only in the point D, and is every where elſe without the ſurface, therefore any line (different from V D), as V F, drawn in one of the conic ſurfaces, is contained on one ſide of the plane; and the ſame line continued in the oppoſite conic ſurface, as V K, is contained on the other ſide of the plane.

Cor. 1. Any ſtraight line, drawn in the plane, V G H, ſo as to meet the line V D, is a tangent of the conic ſurfaces.

Cor. 2. No other plane, beſides the plane V G H, can be drawn ſo as to touch the conic ſurfaces in the line V D without cutting them.

For, R S the common ſection of the plane V G H, and the plane of the baſe, is a tangent to the periphery of the baſe, *Cor.* 1. And, if there were two ſuch planes, there would likewiſe be two tangents of a circle drawn through the ſame point of the periphery, which is abſurd.

Prop. V. *Fig.* 13.

If either of two oppoſite conic ſurfaces be cut by a plane parallel to the baſe of the cone, the ſection is a circle, having its centre in the axis of the cone.

Through V C, the axis of the cone, let two planes be drawn cutting the baſe in the lines C D and C E, and the plane parallel to the baſe, in the lines G H and G L, and the conic ſurfaces in the lines V H D and V L E: then, becauſe the baſe is parallel to the cutting plane, therefore C D is parallel to G H and C E to G L, 16. 11. E. Therefore, on account of equiangular triangles, 4. 6. E.

DC : CV :: HG : GV
CV : CE :: GV : GL
Ex æquo DC : CE :: HG : GL

But $DC = CE$, therefore $HG = GL$. And in like manner it may be ſhewn that any right line, drawn from G to a point in the interſection of the plane, and the conic ſurface, is equal to G H; therefore the ſection is a circle.

Cor. If, through a point ſituated within or without a conic ſurface, two ſtraight lines, both parallel to the plane of the baſe of the cone (that is, parallel to ſtraight lines in that plane), be drawn to cut, or touch the conic ſurface: then the rectangle contained by the two ſegments (between the point and the conic ſurface), of one of the lines when it cuts, or the ſquare of its ſegment when it touches the conic ſurface, is equal to the rectangle contained by the two ſegments of the other line when it cuts, or to the ſquare of its ſegment when it touches the conic ſurface.

For a plane drawn through the two lines will be parallel to the plane of the baſe, 15. 16. E; and it will interſect the conic ſurface in the periphery of a circle: whence the corollary is manifeſt, 35 and 36. 3. E.

Prop. VI. *Fig.* 14.

If two diameters of the baſe of a cone, as A B and C D, interſect one another at right angles, a plane drawn through the vertex of the cone, and one of the diameters, C D, will biſect any ſtraight line, as E F, terminated both ways by one of the conic ſurfaces, and parallel to the other diameter A B.

Through V and E F draw a plane cutting the conic ſurface in the lines V G and V K, and the plane of the baſe in the line G H K; becauſe E F is parallel to A B; therefore G K is parallel both to A B and E F, 16. 11. E; and it is perpendicular to C D; therefore G K is biſected by the diameter C D, 3. 3. E. And, becauſe G K is biſected in H, therefore E F, parallel to G K, is biſected by V H, that is, by the plane drawn through V and C D.

Prop. VII. *Fig.* 15. *Plate* III.

If a point, as B, be aſſumed in the plane of the baſe of a cone, but without the periphery of the baſe, and, from that point, two tangents, B P and B Q, be drawn to the baſe, and likewiſe a ſtraight line, B V, to the vertex of the cone: then any ſtraight line, as E F, parallel to B V, and terminated both ways by one of the conic ſurfaces, is biſected by a plane drawn through V, the vertex of the cone, and cutting the plane of the baſe in the chord P Q.

Becauſe B V and E F are parallel to one another, therefore they are in one plane, 7. 11. E: let the plane, drawn through B V and E F, cut the conic ſurface in the lines V E G, and V F K; and let the ſame plane cut the plane of the baſe in the line B G K, and the plane paſſing through V, and the chord P Q in the line V D H. Becauſe G K is harmonically divided in H and B, *Lem.* 2. therefore E F, parallel to V B, is biſected by the line V H, *Lem.* 6. But D, the point where V H cuts E F, is the point where the plane drawn through V and the chord P Q cuts E F: therefore E F, parallel to B V, is biſected by that plane.

Prop. VIII. *Fig.* 16.

Let a plane, paſſing through the vertex of a cone, cut the plane of the baſe in a diameter of the baſe C D: and let A B, a diameter of the baſe, be perpendicular to C D; and let M N be drawn through the vertex of the cone parallel to A B; then if a right line G K, in the plane C V D, and terminated by one of the conic ſurfaces, be biſected by a plane paſſing through M N, this plane will biſect all right lines terminated by one of the conic ſurfaces and parallel to G K.

Let the plane which biſects G K cut the plane of the baſe in the line P Q, and the plane C V D in the line V H O: through V draw V L parallel to G K, and let it meet C D produced in L. Becauſe M N is parallel to A B; therefore P Q (the common ſection of two planes drawn through M N and A B) is parallel to M N and to A B, 16. 11. E: therefore P Q is perpendicular to C D. Becauſe G K is biſected by V O, and is parallel to V L; therefore C D, the baſe of the triangle C V D, is harmonically divided in L and O, *Cor. Lem.* 6. conſequently, if two tangents of the baſe be drawn from L, the chord that joins the points of contact of theſe tangents will paſs through O, *Cor. Lem.* 2; and it will be perpendicular to the diameter C D: therefore that chord will coincide with the line P Q, which is the only line that can be drawn through O perpendicular to C D. Therefore all right lines, terminated by one of the conic ſurfaces, and parallel to V L or G K, are biſected by the plane V P Q drawn through M N to biſect G K, *Pr.* 7.

If G K be parallel to C D, then C D will be biſected in O, and P Q will coincide with A B; ſo that this propoſition, in this caſe of it, is the ſame as *Prop.* 6.

Cor. If a plane be drawn through M N to biſect any one right line terminated by one of the conic ſurfaces, and parallel to a line G K in the plane V C D, the ſame plane will biſect all right lines terminated by one of the conic ſurfaces and parallel to G K.

For, if not, then the ſame ſtraight line could be biſected by two planes both paſſing through M N, which is abſurd.

Prop. IX. *Fig.* 17.

Let a plane, paſſing through the vertex of a cone, cut the plane of the baſe in a line C D, not paſſing through E the centre of the baſe: draw the diameter, A F B, perpendicular to C D, and produce it to M; ſo that E M may be a third proportional to E F and E B the radius of the baſe of the cone, and draw M V N through the vertex: then if a right line G K, in the plane C V D, and terminated by one of the conic ſurfaces, be biſected by a plane paſſing through M N, this plane will biſect all right lines terminated by one of the conic ſurfaces and parallel to G K.

Let the plane which biſects G K cut the plane of the baſe in the line P Q M, and the plane C V D in the line V H O: through V draw V L parallel to G K, and let it cut C D produced in L. Becauſe V O biſects G K, and V L is parallel to G K, therefore C D, the baſe of the triangle C V D, is harmonically divided in O and L, *Cor. Lem.* 6; therefore if two tangents of the baſe be drawn from L, the chord that joins the points of contact of theſe tangents will paſs through the point O, *Cor. Lem.* 2; but the ſame chord, being produced, likewiſe paſſes through the point M, *Lem.* 4: therefore that chord will coincide with P Q, which is the only right line that can paſs through both the points O and M, therefore all right lines terminated by one of the conic ſurfaces and parallel to L V, or G K, are biſected by the plane V P Q drawn through M N to biſect G K, *Pr.* 7.

Cor. If a plane be drawn through M N to biſect any one right line, terminated by a conic ſurface, and parallel to a line G K, in the plane V C D, or parallel to the plane V C D, that plane will biſect all right lines terminated by a conic ſurface, and parallel to G K.

For, if not, then the ſame right line could be biſected by two planes, both paſſing through M N; which is abſurd.

Prop. X. *Fig.* 18.

Let a plane, paſſing through the vertex of a cone, cut the plane of the baſe in a line C D, which neither cuts nor touches the periphery of the baſe: draw A B F, through E, the centre of the baſe, perpendicular to C D, and take E M, a third proportional to E F, and the radius of the baſe of the cone; and draw M V through the vertex: then if a right line G K, parallel to the plane C V D, and terminated by one of the conic ſurfaces, be biſected by a plane paſſing through M V, this plane will biſect all right lines terminated by one of the conic ſurfaces, and parallel to G K. But the point H, in which the plane, that biſects G K, cuts G K, muſt not be in the ſame right line with the point M, and the vertex of the cone.

Let the plane which biſects G K, cut the plane of the baſe in the line P Q, draw V L parallel to G K; and becauſe G K is parallel to the plane C V D, therefore V L parallel to G K, is in the plane C V D, and it will cut the plane of the baſe in L, a point of the line C D. And, becauſe G K is parallel to V L, therefore they are contained in one plane, 7. 11. E. Let this plane be drawn, and let it cut the conic ſurface in V R and V S, the plane of the baſe in L R S, and the plane V P Q, in V O. Becauſe G K is parallel to V L, and it is biſected by V O, therefore S R, the baſe of the triangle S V R, is harmonically divided in O and L, *Cor. Lem.* 6.; therefore, if two tangents of the baſe be drawn from L, the chord that joins the points of theſe tangents will paſs through the point O, *Cor. Lem.* 2.; but, becauſe L is a point in C D, the ſame chord will paſs through M, *Lem.* 4.; and, becauſe the point O does not fall upon M, therefore the chord will coincide with P Q, which is the only line that can paſs both through O and M. Therefore, all right lines, terminated both ways by one of the conic ſurfaces, and parallel to V L, or G K, are biſected by the plane, V P Q, *Pr.* 7.

Prop. XI. *Fig.* 19.

Let a plane touching a conic ſurface cut the plane of the baſe in a line, C D, which touches the periphery of the baſe in P; then, if a right line, G K, terminated by one of the conic ſurfaces, and parallel to the touching plane, V C D, be biſected by a plane drawn through V P; this plane will biſect all right lines parallel to G K, and terminated by one of the conic ſurfaces.

Through V draw V L parallel to G K: becauſe G K is parallel to the plane V C D, therefore, V L, parallel to G K, is in the plane V C D, and it will cut the plane of the baſe in L, a point in C D. And, becauſe V L is parallel to G K, therefore they are contained in one plane, 7. 11. E.; let this plane be drawn, and let it cut the conic ſurface in the lines V M and V N, the plane of the baſe in the line L M N, and the plane V Q P, in the line V O. Becauſe G K is parallel to V L, and it is biſected by V O, therefore, M N, the baſe of the triangle V M N, is harmonically divided in O and L, *Cor. Lem.* 6. Therefore, if two tangents of the baſe be drawn from L, the chord that joins the two points of contact of theſe tangents will paſs through the point O, *Cor. Lem.* 2.; but the ſame chord likewiſe paſſes through Q, which is one of the points of contact of tangents drawn from L; therefore, the chord coincides with the line Q P. Therefore the plane V Q P, biſects all right lines terminated by one of the conic ſurfaces, and parallel to V L, or G K, *Pr.* 7.

Fig. 20, 21, 22, 23. If a cone be cut by a plane P Q, which neither paſſes through the vertex, nor is parallel to the baſe, then, a plane, as V M N, being drawn through the vertex parallel to the cutting plane, it will neceſſarily meet the plane of the baſe of the cone. The line of common ſection of the parallel plane, and the baſe of the cone M N, may have one or other of three different poſitions; *viz.*

Fig. 20. 1ſt. It may be without the baſe of the cone.

Fig. 21. 2dly. It may touch the periphery of the baſe of the cone.

Fig. 22. and 23. 3dly. It may cut the periphery of the baſe of the cone.

Theſe three different caſes offer three ſections for our conſideration that are very different from one another, and poſſeſs many properties that are peculiar to each, while they have many that are common to all the three.

Def. V. If the line of common ſection, M N, (*fig.* 20.), be without the baſe of the cone, then the plane V M N, drawn through the vertex, will be entirely between the two conic ſurfaces, not meeting either of them. In this caſe, the cutting plane P Q, will meet every line drawn from the vertex in one of the conic ſurfaces, and the curve line of common ſection will ſurround that conic ſurface, and will completely encloſe a ſpace. In this poſition of the cutting plane, the conic ſection is called an ellipſe.

Def. VI. If the line of common ſection M N, (*fig.* 21.) touch the periphery of the baſe, then the plane drawn through the vertex will touch the conic ſurfaces, *Pr.* 4. And the oppoſite ſurfaces will be on different ſides of it. In this caſe alſo the cutting plane will meet every line drawn from the vertex in one of the conic ſurfaces, excepting only the line of contact, V B, in which the touching plane meets that conic ſurface: and as the cutting plane is indefinitely extended along the touching plane without meeting it, it is obvious that the curve line formed by the common ſection of the cutting plane and the conic ſurface does not return into itſelf ſo as to encloſe a ſpace, but it is open on the ſide oppoſite to the vertex of the cone. In this poſition of the cutting plane, the conic ſection is called a parabola.

Def. VII. If the line of common ſection M N (*fig.* 22 & 23.) cut the periphery of the baſe, then the plane drawn through the vertex will divide each of the oppoſite conic ſurfaces into two parts lying on oppoſite ſides of it. In this caſe the cutting plane being indefinitely extended will meet every line drawn from the vertex in thoſe parts of the two conic ſurfaces that lie on the ſame ſide of the plane, through the vertex, as the cutting plane itſelf; and thus two curve lines will be formed by the common interſection, of the cutting plane, and the two oppoſite conic ſurfaces. It is obvious that theſe curve lines may be indefinitely extended, and that they do not return into themſelves ſo as to encloſe a ſpace. In this poſition of the cutting plane the conic ſection, formed by its interſection with one of the conic ſurfaces is called a hyperbola; and the two conic ſections formed by its interſections with the two oppoſite conic ſurfaces, are called oppoſite hyperbolas, or oppoſite ſections.

Def. VIII. The nature of the ſeveral conic ſections defined in the three laſt definitions depends entirely, as we have ſeen, on the relative poſition that the line of common ſection of the plane of the baſe and the plane drawn through the vertex parallel to the cutting plane, has in reſpect to the circle that forms the baſe of the cone. As there will be frequent occaſion to refer to this line, in the following theory of the conic ſections, it will be requiſite, for the ſake of abridging language, to diſtinguiſh it by a peculiar name. For this purpoſe we ſhall call it the *determining line.*

Def. IX. Let a plane, as P Q, (*fig.* 20 and 22.) cut a conic ſurface, or oppoſite ſurfaces, and let M N be the *determining line*, or the common ſection, of the plane of the baſe and the plane drawn through the vertex parallel to the plane P Q: from C, the centre of the baſe of the cone, draw C D perpendicular to M N, and take C E a third proportional to C D and C A or C B, the radius of the baſe: then, a line being drawn from the vertex V to the point E, it will meet the plane P Q in a point G, which is called the centre of the conic ſection, or oppoſite ſections, formed by the common interſection of the plane P Q, and the conic ſurface, or oppoſite ſurfaces.

But, if the *determining line* M N (*fig.* 23.) cut the baſe of the cone, and paſs through its centre, then, the diameter A B being perpendicular to M N, and V G being drawn through the vertex parallel to A B; V G will meet the plane P Q in a point G, which, in this caſe, is the centre of the oppoſite ſections.

Fig. 20, 22, 23. *Cor.* 1. The centre of an ellipſe is a point within the figure; but the centre of two oppoſite hyperbolas is a point without both hyperbolas, and ſituated between them.

For, when the line M N is without the baſe of the cone, the point E and the line V E are within the conic ſurface; but, when M N cuts the baſe, then E and V E are without both of the two conic ſurfaces and between them.

Cor. 2. A parabola has no centre.

Fig. 21. For, in this caſe, the points E and D coincide with the point B, where M N touches the periphery of the baſe; and the line V E coincides with the line V B which does not meet the cutting plane P Q.

Cor. 3. The centre of a conic ſection is never in the axis of the cone, unleſs when the cutting plane is parallel to the baſe of the cone.

Def. X. A right line drawn in the plane of a conic ſection ſo as to meet the curve of the ſection in one point only, and which, being produced both ways, is contained on one and the ſame ſide of the ſection, is called a tangent of the ſection.

Cor. 1. A tangent of a conic ſection is a tangent of the conic ſurface.

For it can meet the conic ſurface only in the point in which it meets the ſection.

Cor. 2. There cannot be more than one tangent of a conic ſection at the ſame point of the curve.

For if there were two tangents, then two planes drawn through them and the vertex of the cone would meet the conic ſurface in the ſame right line without cutting the conic ſurface, which is abſurd. *Cor.* 2. *Pr.* 4

Prop. XII.

A right line, drawn in the plane of a conic ſection, cannot meet the curve in more than two points.

For ſuch a line does not meet the conic ſurface in more than two points. *Cor.* 2.

Prop. XIII.

A right line drawn through a point in a conic ſection, in the ſame plane with it, and parallel to a line drawn from the vertex in the conic ſurface, does not meet the curve of the conic ſection again in another point.

For it does not meet the conic ſurface in another point, *Pr.* 3. Thus, in the parabola, if P Q be drawn parallel to V B, (*fig.* 21.), then P Q meets the curve only in the point P.

Prop. XIV. *Fig.* 24, 25, and 26. *Plate* IV.

Every ſtraight line, as F H, drawn through G, the centre of an ellipſe, or oppoſite hyperbolas, and terminated both ways by the curve, or oppoſite curves, is biſected in the centre.

I. When the *determining line* M N, (*fig.* 24 and 25), does not paſs through the centre of the baſe. Through V, the vertex of the cone, and the line F H, draw a plane cutting the conic ſurface in the lines V H L and V F K, and the plane of the baſe in the line L K M, and the plane V M N in the line V M. Becauſe the point G is in the line V G E; therefore, the line L K M will paſs through the point E. And becauſe F H and V M are the common ſections of the plane V K L, and two parallel planes (*viz.* the plane of the ſection and the plane V M N), therefore F H is parallel to V M, 16. 11. E. And, becauſe C B or C A, the radius of the baſe of the cone, is a mean proportional between C D and C E, and M N is perpendicular to A B; therefore, the chord K L is harmonically divided in E and M, *Lem.* 3. And becauſe L K is the baſe of the triangle K V L, and F H is parallel to V M, therefore, F H is biſected by V E, *Lem.* 6.: that is, F G = G H.

In the ellipſe, when F H (*fig.* 20.) is parallel to M N, it will be perpendicular to a diameter of the baſe drawn perpendicular to the diameter A B; therefore, it is biſected by the plane V A B, which cuts it in G, *Pr.* 6.

II. When the *determining line*, (*fig.* 26.) paſſes through the centre of the baſe. In this caſe, V G is parallel to the diameter A B *Def.* IX. And L K, the common ſection of the plane of the baſe, and the plane V Q K (drawn through V, and the line F G H), is parallel both to A B and to V G, 7. 11. E. But the diameter M N is perpendicular to the diameter A B; therefore, it is alſo perpendicular to K L, and it biſects K L, 3. 3. E. And becauſe F H and V M are the common ſections of two parallel planes (*viz.* the plane of the conic ſection, and the plane V M N), therefore F H is parallel to V M. And becauſe V M biſects the baſe of the triangle K V L, and V G is parallel to that baſe, therefore V G biſects F H parallel to V M. *Lem.* 5.

Definitions.

XI. A ſtraight line drawn through the centre of an ellipſe, or oppoſite hyperbolas, and terminated both ways by the curve or oppoſite curves, is called a diameter of the ellipſe, and a tranſverſe diameter of the oppoſite hyperbolas.

XII. A ſtraight line in the plane of a parabola, as P Q, (*fig.* 21.) drawn parallel to the right line V B, in the conic ſurface (which paſſes through the vertex of the cone, and the point in which the *determining line* touches the periphery of the baſe), is called a diameter of the parabola.

Cor. All the diameters of a parabola are parallel to one another.

XIII. A vertex of a diameter is a point where the diameter meets the curve of the conic ſection.

Cor. A diameter of a parabola has only one vertex, *Pr.* 13.

XIV. A ſtraight line (which is not a diameter of an ellipſe), terminated both ways by the curve of a conic ſection, and biſected by a diameter of the ſection, is ſaid to be ordinately applied to that diameter; or it is called a double ordinate; and the half of it, an ordinate of the diameter.

Prop. XV. *Fig.* 24, 25, and 26.

If a ſtraight line be ordinately applied to a diameter of an ellipſe, or a parabola, or to a tranſverſe diameter of a hyperbola, then all right lines parallel to it and terminated both ways by the ſame curve, or by the oppoſite curve, are ordinately applied to the ſame diameter.

Let R S T (*fig.* 24 and 25.) be ordinately applied to F H, a diameter of an ellipſe or a parabola, or a tranſverſe diameter of a hyperbola or oppoſite hyperbolas; then all other right lines, as P Q, parallel to R T, and terminated by the ſame curve, or the oppoſite curve, are ordinately applied to the ſame diameter F H. Draw a plane through V, the vertex of the cone, and the diameter F H. Then, in the caſe of the ellipſe and hyperbola, when the *determining line* does not paſs through the centre of the baſe, this plane will neceſſarily paſs through the line V E. And, becauſe the plane of the conic ſection is parallel to the plane V M N, therefore R T, in the former plane, is parallel to the latter plane. And becauſe the plane drawn through V, and the diameter F H, paſſes through V E, and biſects R T, which it cuts in S, a point not in the ſame right line with V and E; therefore, the ſame plane will biſect all right lines in either of the oppoſite cones that are parallel to R T. *Pr.* 10. and *Cor.* 9. Therefore, the diameter F H in that plane will biſect all the right lines which it meets, that are parallel to R T, and terminated by the ſection, or either of the oppoſite ſections.

And, when the *determining line* paſſes through the centre of the baſe (*fig.* 26), even, as before, R T is parallel to the plane V M N. And the diameter A B is perpendicular to the diameter M N, and G V is parallel to A B, *Def.* IX; therefore, the plane drawn through V G and F H, which biſects R T, will biſect all right lines in either of the oppoſite cones that are parallel to R T, *Pr.* 8. Therefore, F H in that plane will biſect all the right lines which it meets that are parallel to R T, and terminated by either of the oppoſite hyperbolas.

In the parabola, becauſe the plane of the ſection is parallel to the plane V M N; therefore, R T, (*fig.* 27.) in the former plane, is parallel to the latter plane. And becauſe V B is parallel to F H, therefore a plane may be drawn through them both; let this plane be drawn, and it will biſect all right lines in either of the oppoſite cones that are parallel to R T, *Pr.* 11. Therefore, F H, in that plane, will biſect all the right lines which it meets, that are parallel to R T, and terminated by the curve of the parabola.

Prop. XVI. *Fig.* 28.

A right line, drawn from a vertex of a diameter of an ellipſe, or a parabola, or from the vertex of a tranſverſe diameter of a hyperbola, ſo as to be parallel to a line ordinately applied to that diameter, is a tangent of the curve.

Fig. 28. Let F H be a diameter of an ellipſe or a parabola, or a tranſverſe diameter of a hyperbola, and R S T, a line ordinately applied to that diameter; then F M, drawn from a vertex of the diameter, ſo as to be parallel to R T, is a tangent of the curve. For, if F M be not a tangent, it will cut the ſection again in another point (*Cor.* 2. *Def.* X), let it cut the ſection again in K, and biſect F K in I. Then, if a diameter of the ſection be drawn through I, F K will be ordinately applied to that diameter, *Def.* XIV; therefore that diameter would biſect R T parallel to F K, *Pr.* 15. Therefore R T would be biſected by two different diameters; *viz.* by the diameter F H, and by that drawn through I. But, in the ellipſe and hyperbola, all the diameters paſs through the centre; and, in the parabola, they are all parallel to one another; therefore two diameters of a conic ſection will cut every ſtraight line (which does not paſs through the centre of the ellipſe and hyperbola) in two different points. Therefore R T cannot be biſected by two different diameters. Therefore F M, parallel to R T, does not cut the curve again; that is, F M is a tangent of the conic ſection.

Cor. 1. If R T be ordinately applied to the diameter F H, it is parallel to a tangent, F M, at a vertex of that diameter.

For there cannot be two tangents of a conic ſection at the ſame point of the curve.

Cor. 2. All right lines ordinately applied to the ſame diameter of a conic ſection are parallel to one another.

For they are all parallel to a tangent at a vertex of that diameter.

Prop. XVII. *Fig.* 24 and 27.

A diameter of a conic ſection being given, to draw a right line that ſhall be ordinately applied to that diameter.

Fig. 24. Let F H be a diameter of an ellipſe; draw a plane through the vertex V, and the diameter F H, cutting the plane of the baſe in the chord K L, which neceſſarily paſſes through the point E; draw tangents of the baſe from K and L, and let them interſect in O. Then O is a point in the *determining line* M N; *Lem.* 4; and V O being drawn to the vertex of the cone, it is in the plane V M N, and parallel to the plane of the ellipſe. Now, all ſtraight lines, as P Q and R T, in the plane of the ellipſe, drawn parallel to V O, are ordinately applied to the diameter F H; for theſe lines are all biſected by the plane V K L, that is, by F H in that plane, *Pr.* 7.

The conſtruction is exactly the ſame for the hyperbola.

Fig. 27. In the parabola the plane drawn through the diameter F H, paſſes through V B, parallel to F H, and it cuts the plane of the baſe in a chord B K, drawn from the point where the *determining line* M N, touches the periphery of the baſe; in this caſe draw K O, a tangent of the baſe, interſecting M N in O; then, as before, V O, drawn to the vertex, is parallel to the plane of the parabola; and all right lines, as R T, P Q, in that plane, parallel to V O, are ordinately applied to the diameter F H, *Pr.* 7.

Fig. 20, 21, 22, and 23. In all the conic ſections, when the plane drawn through the vertex of the cone, and a diameter P Q, cuts the plane of the baſe in a diameter of the baſe A B; then all right lines, as R T, in the plane of the ſection, drawn parallel to the *determining line* M N, are ordinately applied to the diameter P Q. For, if a diameter of the baſe be drawn parallel to M N, that diameter will be parallel to R T, and perpendicular to the diameter A B; therefore R T is biſected by the plane V A B, that is, by P Q, the diameter of the ſection in that plane, *Pr.* 6.

Prop. XVIII.

Tangents drawn from the vertices, of a diameter of an ellipſe, or of a tranſverſe diameter of a hyperbola, are parallel to one another; but tangents of a conic ſection, drawn from the vertices of two different diameters, are not parallel.

Let a right line be ordinately applied, to a diameter of an ellipſe, or to a tranſverſe diameter of a hyperbola, *Pr.* 17; then the tangent of the curve at either vertex of the diameter is parallel to that right line; conſequently, the two tangents at the extremities of the diameter are parallel to one another.

And becauſe a right line ordinately applied to one diameter of a conic ſection is not ordinately applied to another diameter; therefore a tangent at a vertex of one diameter is not parallel to a tangent at a vertex of another diameter.

Cor. If there be two parallel tangents of an ellipſe, or of oppoſite hyperbolas; theſe tangents are drawn from the extremities of a diameter of the ellipſe, or of a tranſverſe diameter of the hyperbolas.

PROP. XIX. *Fig.* 28.

A ſtraight line terminated both ways by the curve of a conic ſection, and parallel to a tangent, is ordinately applied to the diameter drawn through the point of contact.

Let R T, terminated by the curve of a conic ſection, be parallel to a tangent of the curve F M; then R T is ordinately applied to the diameter F H, drawn through the point of contact. Draw P Q ordinately applied to F H, *Pr.* 17. Then P Q is parallel to the tangent F M, *Cor.* 1. *Pr.* 16; therefore P Q is alſo parallel to R T. Conſequently, R T is ordinately applied to F H, *Pr.* 15.

PROP. XX. *Fig.* 29.

A ſtraight line G T, drawn from the centre of oppoſite hyperbolas ſo as to be parallel to F O and H I lines touching the curves at the vertices of a tranſverſe diameter F H, biſects all lines, as R S, terminated by the oppoſite hyperbolas and parallel to the tranſverſe diameter: and if a tranſverſe diameter, F H, be drawn parallel to a ſtraight line, as R S, terminated by oppoſite hyperbolas, and biſected by a line G T drawn through the centre, this line is parallel to F O and H I the tangents at the vertices of the tranſverſe diameter.

Draw the diameter R P, join S, P, and produce F H to cut S P in Q. Becauſe R S is parallel to F H, and R G = G P; therefore S Q = Q P: therefore S P is parallel to H I or F O, *Cor.* 1. *Pr.* 16. But G T is parallel to F O or H I: therefore G T is parallel to S P. Therefore it is manifeſt that G T biſects R S, 2. 6. E.

Again, if G T biſect R S, then is G T parallel to H I or F O; for, becauſe R T = T S, and R G = G P, therefore G T is parallel to S P, 2. 6. E. And becauſe F H is parallel to R S, therefore S Q = Q P, 2. 6. E.: therefore S P is parallel to H I, *Cor.* 1. *Pr.* 16. Therefore G T is parallel to H I or F O.

Def. XV. Let the *determining line* M N (*fig.* 30.) of two oppoſite hyperbolas cut the periphery of the baſe of the cone in M and N, and let tangents of the baſe be drawn from theſe points (which tangents will paſs through the point E when M N does not paſs through the centre of the baſe of the cone, *Lem.* 4; but they will both be parallel to the diameter A B and to the line V G, when M N does paſs through the centre): through the line V G, and the two tangents P M and Q N, let two planes be drawn cutting the plane of the hyperbolas in the lines G P and G Q, interſecting in the centre of the hyperbolas: then theſe lines are called aſymptotes of the hyperbolas.

Cor. 1. The aſymptotes do not meet the hyperbolas.

For the planes V P M and V Q N meet the conic ſurfaces only in the lines V M and V N produced, *Pr.* 4.: therefore the lines G P and G Q, in thoſe planes, are without the conic ſurfaces in which the hyperbolas are.

Cor. 2. The aſymptotes G P and G Q are parallel to V M and V N, the lines in which the planes V M P and V N Q touch the conic ſurfaces.

For the plane V M P cuts the plane of the hyperbolas and the plane V M N (which are parallel planes) in the lines G P and V M; and the plane V N Q cuts the ſame planes in the lines G Q and V N.

Cor. 3. If a line be drawn parallel to one of the aſymptotes through a point in one of the hyperbolas, that line does not meet the ſame hyperbola, nor the oppoſite one, again in another point.

For a line parallel to one of the aſymptotes is parallel to one of the lines V M and V N in the conic ſurface; therefore it does not meet either of the conic ſurfaces again in another point, *Pr.* 3.

Cor. 4. A ſtraight line in the plane of the hyperbolas, as F H, drawn through the centre of the hyperbolas within the angle contained by the aſymptotes, will meet both the hyperbolas.

Becauſe the aſymptotes are parallel to V M and V N, therefore, if V O be drawn parallel to F H, it will be within the angle M V N; and it is plain that F H, parallel to V O, meets both the conic ſurfaces.

LEMMA VII. *Fig.* 31.

Let A B and A C be two right lines that meet one another: then if B C, drawn through D, and terminated by A B and A C, be biſected in D, no other ſtraight line, terminated by A B and A C, and drawn through D, will be biſected in that point.

Draw G H through D, and D E parallel to A C; becauſe B D = D C, therefore A E = E B, 2. 6. E. Therefore A E and E G are not equal to one another: and, conſequently, G D and D H are not equal.

PROP. XXI. *Fig.* 30.

If a ſtraight line, terminated by the aſymptotes, as K L or S T, touch either of the hyperbolas, it is biſected in the point of contact: and if the middle point of a ſtraight line, as K L or S T, terminated by the aſymptotes be in either of the hyperbolas, that line is a tangent of the curve. Draw the diameter F H and let *a b* be ordinately applied to it, *Pr.* 17: alſo draw *d e*, between M V and V N, parallel to *a b*. Conceive a plane to be drawn through V G and F H, and let this plane cut the plane M V N in the line V O. It is manifeſt that V O is parallel to the diameter F H, 16. 11. E. And becauſe a plane drawn through V G biſects *a b*, the ſame plane will biſect all right lines in either of the oppoſite cones that are parallel to *a b*, *Cor.* 9; therefore it will biſect *d e*; that is, *d o* = *o e*. Becauſe K L is a tangent, it is parallel to *a b*, *Cor.* 1. *Pr.* 16, and, conſequently, to *d e*. And becauſe the aſymptotes are parallel to V M and V N, *Cor.* 2. *Def.* XV., and F H is parallel to V O, and *d e* to K L, it is plain that K L and *d e* are ſimilarly divided in H and O: therefore K H = H L.

Again, if K L meets the hyperbola in H, and is biſected there, it is a tangent. For, if not, then, a line being drawn between the aſymptotes to touch the hyperbola in H, it would likewiſe be biſected in H as has already been ſhewn: which is abſurd. *Lem.* 7. Therefore K L is a tangent.

PROP. XXII. *Fig.* 32. *Plate* V.

If a right line, that cuts an hyperbola or oppoſite hyperbolas, likewiſe cuts both the aſymptotes; the ſegments between the hyperbola, or hyperbolas, and the aſymptotes, will be equal.

Let the right line D E cut a hyperbola in S and P, and the aſymptotes in D and E: draw the tranſverſe diameter F H to biſect S P, and let K L be drawn to touch the hyperbola in H: becauſe F H biſects S P, therefore S P is parallel to the tangent K L, *Cor.* 1. *Pr.* 16, but K L is biſected in H, *Pr.*21.; therefore D E, parallel to K L, is biſected in Q: and becauſe D E and S P are both biſected in Q, therefore D S and S E are reſpectively equal to S P and P D.

Next let SR cut the two oppoſite hyperbolas in S and R; and the aſymptotes in N and I: draw G T through the centre to biſect S R; and draw the tranſverſe diameter F H parallel to S R; and let K L touch one of the hyperbolas at H, and draw K M parallel to S R: becauſe G T biſects S R parallel to F H, therefore G T is parallel to K L, *Pr.* 20: becauſe K M and F H are both parallel to S R, therefore they are parallel to one another: but K L is biſected at H, *Pr.* 21, therefore L M is biſected at G, and K M is biſected at O, 2. 6. E; therefore N I, parallel to K M, is biſected at T. And, becauſe S R and N I are both biſected at T, therefore the ſegments S N and N R are reſpectively equal to the ſegments R I and I S.

Prop. XXIII. *Fig.* 32.

The curve of an hyperbola approaches the nearer to the aſymptote the farther it is continued; and, if continued far enough, the diſtance of the curve from the aſymptote will become leſs than any aſſigned diſtance how ſmall ſoever.

Aſſume any point, as A in the hyperbola, and draw A X parallel to the aſymptote G C; then A X does not meet the hyperbola again, *Cor.* 3. *Def.* XV: through A draw any line B C to a point, as Z in the curve, and let B C meet the aſymptotes in B and C, and draw B X perpendicular to A X, and Z Y perpendicular to the aſymptote G C: becauſe A B = Z C, *Pr.* 21, it is plain that B X = Z Y: now the more diſtant the point Z is, the nearer is the line A B to the line A X, and the leſs is B X, or Z Y the diſtance of the curve from the aſymptote. And becauſe A B may be drawn ſo as to make B X leſs than any aſſigned line, therefore a point of the curve may be found that ſhall be nearer to the aſymptote than any aſſigned diſtance.

Definitions.

Fig. 30. *Plate* IV. XVI. If a ſtraight line be drawn through the centre of oppoſite hyperbolas parallel to the tangents S T and K L at the vertices of a tranſverſe diameter F H, and a part of that line biſected in the centre, as I R, be taken equal to the ſegments S T and K L (it is plain that S T = K L) of the tangents terminated by the aſymptotes; then I R is called a ſecond diameter of the hyperbolas, and the extremities of it are called the vertices of the ſecond diameter.

But the word diameter is often uſed to ſignify a ſtraight line drawn through the centre of an ellipſe or oppoſite hyperbolas, without regard to the magnitude of ſuch line.

XVII. A ſtraight line, terminated by two oppoſite hyperbolas and biſected by a ſecond diameter, is ſaid to be ordinately applied to that diameter; or it is called a double ordinate, and the half of it, an ordinate.

XVIII. Two diameters of an ellipſe, or of oppoſite hyperbolas, that are mutually parallel to the ordinates of one another, are called conjugate diameters, or they are ſaid to be conjugate to one another.

Prop. XXIV.

If a diameter of an ellipſe, or of oppoſite hyperbolas, be parallel to the ordinates of another diameter, theſe two are conjugate diameters.

The demonſtration of this propoſition, in the caſe of the hyperbola, is manifeſt from *Prop.* 20th; for the ordinates of a tranſverſe diameter of a hyperbola are parallel to a tangent at a vertex of the diameter, *Cor.* 1. *Pr.* 16.

Fig. 33. *Plate* V. In the ellipſe, let the diameter E D be parallel to P Q S an ordinate of the diameter F H; draw the diameter P R and join S R cutting E D in T. Becauſe P Q = Q S, and P G = G R; therefore S R is parallel to F H. And becauſe E D is parallel to P Q S, and P G = G R; therefore R T = T S. Therefore R S is an ordinate of the diameter E D, *Def.* XIV, and it is parallel to F H; therefore E D and F H are conjugate diameters, *Def.* XVIII.

Cor. It a diameter of an ellipſe, as E D, be parallel to F O, a tangent at a vertex of another diameter F H; then F H is parallel to D I, a tangent at a vertex of E D.

For a tangent at a vertex of a diameter is parallel to the ordinates of that diameter.

Def. XIX. When a ſtraight line drawn through a point, ſituated within or without a cone, meets one, or both, of the conic ſurfaces in two points, it is called a ſecant; and the two parts of ſuch a line, between the point through which it is drawn and the conic ſurface or ſurfaces, are called the ſegments of the ſecant. And when a line, drawn from a point without a cone, touches one of the conic ſurfaces; that part of it between the point from which it is drawn and the conic ſurface is denoted by the word tangent in the following propoſitions.

Prop. XXV. *Fig.* 34, 35, and 36.

If a ſtraight line be drawn from the vertex of a cone to a point, as B, in the plane of the baſe, but not in the periphery of the baſe; and, through any point, as P, ſituated without or within the cone, another ſtraight line, parallel to the former, be drawn to cut or touch the conic ſurface, or oppoſite ſurfaces; then the ſquare of the line drawn from the vertex of the cone to the point B is to the rectangle under the ſegments of the ſecant, or to the ſquare of the tangent, drawn from the point P, as the rectangle under the ſegments of any line drawn from B to cut the baſe of the cone, is to the rectangle under the ſegments of any line, parallel to the baſe of the cone, drawn through the point P, to cut the conic ſurface.

Fig. 34. Let the point B be without the baſe of the cone, and let Q R, drawn through P without or within the conic ſurface, be parallel to V B, and let it cut the conic ſurface in Q and R: through P and the line V B draw a plane cutting the conic ſurface in the lines V G and V H, and the plane of the baſe in the line B G H; and through P draw L K parallel to G H. Becauſe V B and P Q R are parallel, therefore the line P Q R is contained in the plane B V P, 7. 11. E; and the points Q and R are in the lines V H and V G, the common ſections of the plane and the conic ſurface. Becauſe Q P is parallel to V B and L K to G H, therefore the triangle Q P L is equiangular to the triangle V B H, and the triangle P K R to the triangle V G B: therefore 4. 6. E.

$$VB : PR :: BG : PK$$

$$VB : PQ :: BH : PL$$

Conſequently, $VB^2 : PR \times PQ :: BG \times BH : PK \times PL$, 23. 6. E. But the rectangle B G × B H is equal to the rectangle under the ſegments of any other line drawn from B to cut the baſe of the cone, 35 and 36. 3. E; and the rectangle P K × K L is equal to the rectangle under the ſegments of any other line, parallel to the plane of the baſe, drawn from P to cut the conic ſurface, *Cor. Pr.* 5; and hence the proportion is manifeſt in this caſe.

Fig. 35. And if the point B be within the baſe of the cone, and a ſtraight line (as P Q R), parallel to the line

V B that joins the point B and the vertex of the cone, be drawn to cut the oppoſite ſurfaces through a point P ſituated without or within the cone: the propoſition may be demonſtrated in this caſe, in the very ſame words as in the former caſe.

Fig. 36. And if the point P be without the cone as well as the line V B, and P S, parallel to V B, be drawn to touch the conic ſurface, inſtead of cutting it; then the plane P V B will meet the conic ſurface in a line V S M; and B M will touch the baſe of the cone, and P N, parallel to B M, will touch the conic ſurface. And becauſe the two triangles S P N and V B M are equiangular, therefore,

$$VB : PS :: BM : PN$$

$$\text{And } VB^2 : PS^2 :: BM^2 : PN^2$$

But BM^2 is equal to the rectangle under the ſegments of any line drawn from B to cut the baſe of the cone; and PN^2 is equal to the rectangle under the ſegments of any line, parallel to the baſe of the cone, drawn from P to cut the conic ſurface; and hence the propoſition is manifeſt in this caſe alſo.

Prop. XXVI. *Fig.* 37.

If a point be aſſumed without or within a cone, and two lines be drawn through it to meet a conic ſurface, or oppoſite ſurfaces, and ſo as to be parallel to two ſtraight lines given by poſition; then the rectangle under the ſegments of the ſecant, or the ſquare of the tangent, parallel to one of the lines given by poſition, has to the rectangle under the ſegments of the ſecant, or to the ſquare of the tangent, parallel to the other line given by poſition, a ratio that is conſtantly the ſame, wherever the point (from which the lines are drawn) is aſſumed without or within the cone.

Fig. 37. Let V B and V C be two ſtraight lines, drawn from the vertex of a cone to the plane of the baſe, and given by poſition (or parallel to lines given by poſition); and let P Q and M N be two ſtraight lines drawn through any aſſumed point, as R, to cut the conic ſurface, and ſo as to be reſpectively parallel to C V and V B: and as CV^2 is to the rectangle $CK \times CL$ (contained by the ſegments of any line drawn from C to cut the baſe of the cone), ſo let D, any aſſumed line, or magnitude, be to E; and as VB^2 is to $BG \times BH$ (the rectangle contained by the ſegments of any line drawn from B to cut the baſe of the cone), ſo let F be to E; and draw S T parallel to the baſe of the cone through the point R; then, *Pr.* 24.
$(CV^2 : CK \times KL$, or$)\ D : E :: PR \times RQ : SR \times RT$, and $BV^2 : BG \times GH$, or$)\ F : E :: MR \times RN : SR \times RT$. Therefore invertendo and ex æquo,

$$D : F :: PR \times RQ : MR \times RN.$$

And, as the ſame reaſoning applies wherever the point R is aſſumed, therefore the ratio of the rectangles $PR \times RQ$, and $MR \times RN$ is the ſame with, or equal to, the conſtant ratio of D to F, wherever the point R is aſſumed.

And, in like manner, may the propoſition be demonſtrated in all other caſes, or in all poſitions of the lines P Q, and M N, whether they cut, or touch, the ſame or oppoſite ſurfaces.

Prop. XXVII. *Fig.* 38.

If a point be aſſumed in the curve of an hyperbola, and a ſtraight line be drawn through it to cut both the aſymptotes; the rectangle, contained by the ſegments intercepted between the point in the curve and the aſymptotes, will be equal to the ſquare of the ſemidiameter to which the ſtraight line is parallel.

Firſt, let the ſtraight line E M N, drawn through E in the curve of a hyperbola and cutting the aſymptotes in M and N, be parallel to the tranſverſe diameter, G H; join H E, and produce it to meet the aſymptotes in R and S: it is obvious that the triangle R G H is equiangular to the triangle R E N, and the triangle G H S to the triangle S E M; therefore, 4. 6. E.

$$NE : ER :: GH : HR$$

$$SH : GH :: SE : EM$$

And, becauſe $SH = ER$, and $SE = HR$, *Pr.* 22. therefore,

$$\text{ex æquo } NE : GH :: GH : EM$$

$$\text{conſequently, } ME \times EN = GH^2,\ 17.\ 6.\ E.$$

Next, when the line is parallel to a ſecond diameter. And if it touch the curve at the point H through which it is drawn, as K L; then the two ſegments, K H, and H L, are equal to one another, *Pr.* 13, and to the ſemidiameter G P, to which K L is parallel, *Def.* XVI; whence the propoſition is manifeſt. But if a line, as D F, drawn through the point of the curve, E, parallel to the ſecond diameter G P, do not touch the hyperbola, let K L, parallel to G P, touch the hyperbola in H, and join H E, cutting the aſymptotes in R and S. Becauſe K L and D F are parallel (being, both, parallel to G P), therefore the triangles, R H L, and K H S, are reſpectively equiangular to the triangles R E F and D E S; therefore,

$$FE : ER :: HL : HR$$

$$SH : HR :: SE : ED$$

And, becauſe $SH = ER$ and $SE = HR$, therefore,

$$\text{ex æquo } FE : HK :: HL : ED$$

$$\text{conſequently, } FE \times ED = HK \times HL = GP^2.$$

Cor. If any number of ſtraight lines, all parallel to one another, meet the two aſymptotes and the hyperbola or oppoſite hyperbolas; the rectangles contained by the ſegments of the parallels, intercepted between the aſymptotes and the curve, will be all equal to one another.

For each of the rectangles is equal to the ſquare of the ſemidiameter drawn parallel to the lines.

Prop. XXVIII. *Fig.* 38.

If a point be aſſumed without or within a conic ſection, and two ſtraight lines be drawn through it to cut or touch the ſection or oppoſite ſections, and ſo as to be parallel to two lines given by poſition; then the rectangle under the ſegments of the ſecant, or the ſquare of the tangent, parallel to one of the lines given by poſition, will have to the rectangle under the ſegments of the ſecant, or to the ſquare of the tangents parallel to the other line given by poſition, a ratio that is always the ſame, wherever the point (through which the lines are drawn), is aſſumed without or within the ſection. And in the ellipſe and hyperbola, or oppoſite hyperbolas, the conſtant ratio is equal to that of the ſquares of the diameters drawn parallel to the lines given by poſition.

For ſecants and tangents of a conic ſection are ſecants and tangents of a conic ſurface, and thus the firſt part of this propoſition is included in propoſition 25.

And becauſe the diameters of an ellipſe interſect in the centre, and are biſected there, *Pr.* 14; therefore the ratio of the rectangles under the ſegments of the ſecants, is, in this caſe, the ſame with the ratio of the ſquares of the ſemidiameters, or the ſame with the ratio of the ſquares of the diameters themſelves: and thus the ſecond part of the propoſition, in as much as it regards the ellipſe, is manifeſt from the firſt part.

It remains to demonſtrate the ſecond part of the propoſition in the caſe of the hyperbola. Aſſume any point, as F, (*fig.* 38.), in one of the aſymptotes, and through F draw

BI and CE (terminated by the hyperbola, or oppoſite hyperbolas), parallel to two ſemidiameters GP and GH; and let BI, and CE, or theſe lines produced, cut the other aſymptote in D and A. Becauſe $BA = FI$, *Pr.* 22; therefore $BF \times FI = BF \times BA = GH^2$; and, in like manner, $EF \times FC = DC \times CF = GP^2$, *Pr.* 27. Therefore the ratio of the ſquares of the ſemidiameters GH and GP, or the ratio of the ſquares of the diameters themſelves, is equal to the ratio of the rectangles $BF \times FI$ and $EF \times FC$. And becauſe the ratio of the rectangle $BF \times FI$ to the rectangle $EF \times FC$ is equal to the ratio of the rectangles under the ſegments of any lines terminated by the curve or curves that interſect one another, and are parallel to BI and FD (the ſquares of the tangents being taken when the lines touch the curve inſtead of cutting it), therefore, in the caſe of the hyperbola alſo, the ſecond part of the propoſition is manifeſt from the firſt part.

Cor. 1. If two tangents be drawn to an ellipſe, or a hyperbola, or oppoſite hyperbolas, from the ſame point, then theſe tangents are proportional to the diameters, or ſemidiameters, drawn parallel to the tangents.

For the ſquares of the tangents are proportional to the ſquares of the diameters.

Cor. 2. If a right line be ordinately applied to a diameter of an ellipſe, or to a tranſverſe diameter of a hyperbola; then as the ſquare of the diameter is to the ſquare of the conjugate diameter, ſo is the rectangle contained by the abſciſſes of the diameter, between the vertices and ordinate, to the ſquare of the ordinate.

For the double-ordinate is biſected by the diameter, and it is parallel to the conjugate diameter.

Prop. XXIX. *Fig.* 39.

If an ordinate be drawn to a ſecond diameter of oppoſite hyperbolas; the ſquare of this ſecond diameter is to the ſquare of the conjugate diameter, as the ſum of the ſquares of the ſecond diameter, and of the part of it between the centre and the ordinate, is to the ſquare of the ordinate.

Let PQ (*fig.* 39.) be a ſecond diameter of two oppoſite hyperbolas, and FH the diameter conjugate to it, and let MO be an ordinate to PQ: draw MN parallel to PQ; then MN will be an ordinate of the diameter FH; *Def.* XX.

Therefore, $GH^2 : GP^2 :: FN \times NH$, or $GN^2 - GH^2 : MN^2$, *Cor.* 2. *Pr.* 27:
therefore $GH^2 : GP^2 :: GN^2$, or $MO^2 : GP^2 + MN^2$ 12. 5. E. and invertendo, $GP^2 : GH^2 :: GP^2 + MN^2 : MO^2$.

Prop. XXX. *Fig.* 40.

If a right line, as PT, drawn through a point P in the ſurface of a cone ſo as to be parallel to a right line VB contained in the conic ſurface, meet two parallel lines (in the points R and S) that cut or touch the conic ſurface or oppoſite ſurfaces: then PR is to PS as the rectangle under the ſegments of the ſecant, or the ſquare of the tangent, drawn through the point R, is to the rectangle under the ſegments of the ſecant or to the ſquare of the tangent, drawn through the point S.

Through the two parallels PT and VB (*fig.* 40.) draw a plane cutting the conic ſurface again in the line VA, and the plane of the baſe in the line BA; and, through R and S, draw MN and HG parallel to AB. Becauſe PT is parallel to VB and RN to SG, therefore RNGS is a parallelogram; and $RN = GS$. It is obvious that the triangles PMR and PHS are equiangular: therefore PR is to PS as MR is to HS, 4. 6. E, or as $MR \times RN$ is to $HS \times SG$, 1. 6. E. But $MR \times RN$ and $HS \times SG$ are reſpectively equal to the rectangles contained by the ſegments of any two lines, parallel to the baſe of the cone, drawn through R and S to cut the conic ſurface, *Cor. Pr.* 5. and hence the propoſition is manifeſt, when PT meets two lines parallel to the plane of the baſe.

And if PT meet two parallel lines DE and IK, not parallel to the plane of the baſe; then, let the ſame conſtruction be made as before: and becauſe DE is parallel to IK, and MN to GH; therefore,

$DR \times RE : MR \times RN :: IS \times SK : HS \times SG$;

Alternando, $DR \times RE : IS \times SK :: MR \times RN : HS \times SG$. Therefore, as is obvious from what has already been ſhewn,

$$PR : PS :: DR \times RE : IS \times SK.$$

And if S be without the cone and the line drawn through it touch the conic ſurface inſtead of cutting it, the reaſoning is ſtill the ſame, when the ſquare of the tangent is taken in place of the rectangle under the ſegments of the ſecant.

Prop. XXXI.

If two points be aſſumed in the diameter of a parabola, or in a right line drawn through a point in the curve of an hyperbola parallel to one of the aſymptotes, and two parallel lines be drawn from theſe points to cut, or touch, the curve or oppoſite curves; then, as the rectangle under the ſegments of the ſecant or the ſquare of the tangent, drawn from one of the aſſumed points, is to the rectangle under the ſegments of the ſecant, or to the ſquare of the tangent, drawn from the other aſſumed point, ſo is the ſegment of the diameter of the parabola, or of the line parallel to the aſymptote, between the firſt aſſumed point and the curve, to the ſegment of the ſame line between the ſecond aſſumed point and the curve.

Becauſe all the diameters of a parabola, *Def.* XIII. and all the ſtraight lines drawn parallel to an aſymptote of a hyperbola, *Cor.* 2. *Def.* XV. are parallel to a right line contained in the conic ſurface; and becauſe ſecants, and tangents of a parabola, or a hyperbola, are ſecants and tangents of a conic ſurface: therefore it is manifeſt that this propoſition is included in the laſt propoſition.

Cor. The ſquares of the ordinates drawn to a diameter of a parabola are proportional to the abſciſſes of the diameter between the ordinates and the vertex.

Fig. 43. For the double ordinates of a diameter of a parabola, as GFD and LKE are parallel to one another; *Cor. Def.* XVII. therefore, by this propoſition,

$GF \times FD$, or $GF^2 : LK \times KE$, or $LK^2 :: AF : AK$.

Prop. XXXII. *Fig*, 41, 42, and 43.

If an ordinate be drawn to a diameter of a conic ſection, which is not a ſecond diameter of a hyperbola: then, in the ellipſe, the ſquare of the ordinate is equal to a rectangle contained by an abſciſs of the diameter and a conſtant line, deficient by a rectangle ſimilar to that contained by the conſtant line and the diameter; and, in the hyperbola, the ſquare of the ordinate is equal to a rectangle contained by an abſciſs of the diameter, and a conſtant line, exceeding by a rectangle ſimilar to that contained by the conſtant line and the diameter: and in the parabola, the ſquare of the ordinate is equal to a rectangle contained by the abſciſs of the diameter and a conſtant line.

Let AB (*fig.* 41 and 42.) be a diameter of an ellipſe, or a tranſverſe diameter of a hyperbola, FG an ordinate of it, and DE the conjugate diameter; draw AH perpendicular to AB and equal to a third proportional to AB and DE, and join B H: draw F L parallel to A H, and complete the parallelograms A K, F N and A M. It is obvious that B A is to A H as B F is to F L, 4. 6. E, or as $BF \times FA$ is to $FL \times FA$ or the rectangle F N, 1. 6. E. And becauſe A H is a third proportional to B A and E D, therefore,

$BA : AH :: BA^2 : DE^2$, *Cor.* 2, 20. 6. E. $:: AF \times FB : FG^2$. *Cor.* 2. *Pr.* 28.

Therefore,

$AF \times FB : FG^2 :: AF \times FB :$ rect. F N, 14. 5. E.

Therefore $GF^2 =$ rectangle F N. Now, in the ellipſe, the rectangle F N is deficient from the rectangle A M, contained by the abſciſs A F and the line A H (which is the ſame for all the ordinates) by the rectangle N M, ſimilar to the rectangle A K, contained by A H and A B; and, in the hyperbola, the rectangle F N exceeds the rectangle A M by the rectangle N M, ſimilar to the rectangle A K.

In the parabola (*fig.* 43.) let one ordinate of a diameter be pitched upon, as L K, and take A H, a third proportional to the abſciſs A K and the ordinate L K; then, if F G be any other ordinate,

$LK^2 : FG^2 :: AK : AF$, (*Cor. Pr.* 31) $:: AK \times AH : AF \times AH$.

And becauſe $LK^2 = AK \times AH$, therefore $FG^2 = AF \times AH$, the rectangle contained by the abſciſs A F and the line A H, which is the ſame for all the ordinates of the diameter.

Def. XX. The conſtant line A H is called the parameter of the diameter A B; and, in the ellipſe and hyperbola, it is a third proportional to the diameter A B, and the conjugate diameter D E; but, in the parabola, it is a third proportional to the abſciſs of any one ordinate of a diameter, and the ordinate itſelf.

Scholium.

The phraſes "deficient" and "exceeding by a rectangle ſimilar to another rectangle," occur in Euclid's Elements, 27 and 28. 6. E. although they are now generally diſuſed by geometricians; and, it muſt be confeſſed, they are far from expreſſing the meaning they are intended to convey, in a ſimple and perſpicuous manner. Theſe expreſſions have been uſed in enunciating this propoſition, with the view of drawing the attention to the diſtinguiſhing circumſtances from which the ſeveral conic ſections derived their names. For Apollonius gave the name of the ellipſe to one of theſe curves, on account of the defect of the ſquare of the ordinate from the rectangle contained by the abſciſs and the parameter: and he called another of them an hyperbola, from the exceſs of the ſame ſquare above the ſame rectangle; and the third a parabola, on account of the exact equality of the ſame two ſpaces.

Prop. XXXIII. *Fig.* 44. *Plate* VI.

Let a ſcalene cone be cut by a plane drawn through the axis perpendicular to the plane of the baſe, making the triangular ſection V A B; and let V D, cutting A B produced, in D, be drawn ſo as to make the angle B V D equal to the angle V A B; and let I E be drawn in the plane of the baſe perpendicular to A D: then, if a point be aſſumed in the plane of the baſe of the cone, but without the baſe, the ſquare of the line drawn from that point to the vertex of the cone is greater than, or equal to, or leſs than, a rectangle contained by the ſegments of any line drawn from the ſame point to cut the baſe of the cone, according as the aſſumed point is on the ſame ſide of the line I E as the baſe of the cone, or in the line I E, or on the oppoſite ſide of the line I E.

For, let I be any point in the line I E, and draw I V to the vertex, and I K to cut the baſe of the cone through the centre C. Becauſe the angle B V D is equal to the angle B A V, therefore V D is a tangent of a circle deſcribed about the triangle A V B, 32 3. E.; therefore $VD^2 = AD \times DB$ (36. 3. E.) $= DC^2 - CB^2$, 6. 2. E.: to theſe equals add DI^2; and $VD^2 + DI^2 = DC^2 + DI^2 - CB^2$. But it is evident that D I is perpendicular to the plane A V D; therefore, $VD^2 + DI^2 = VI^2$, 47. 1. E.; and $DC^2 + DI^2 - CB^2 = IC^2 - CL^2 = KI \times IL$, 6. 2. E. Therefore, $KI \times IL = VI^2$.

Secondly, let M be a point, without the baſe of the cone, and on the ſame ſide of the line, I E, as the baſe; and, let a plane drawn through M V, and the centre of the baſe, cut the cone in the triangle, K V L, and the plane of the baſe in the line K L M: produce K M to meet I E in I, and draw I V. It has been ſhewn that $IV^2 = IK \times IL$; therefore, if a circle be deſcribed about the triangle K V L, V I will be a tangent of that circle (32. 3. E.), and the line V M, will cut its periphery in a point *m*, ſituated between V and M; and becauſe V, *m*, L, and K are points in the ſame circle, therefore $VM \times Mm = KM \times ML$, 36. 3. E. But VM^2 is greater than $VM \times Mm$; therefore it is alſo greater than $KM \times ML$.

Thirdly, let N be a point in the plane of the baſe of the cone on the oppoſite ſide of the line I E; and, the ſame conſtruction being made as before, it is manifeſt that V N will be entirely without the circle deſcribed about the triangle K V L (of which V I is a tangent); and that V N, when produced, will cut the periphery as at *n*; then $nN \times NV = NK \times NL$. But NV^2 is leſs than $nN \times NV$; therefore it is leſs than $NK \times NL$.

Cor. If I be a point in the plane of the baſe of the cone, ſuch that $IV^2 = IK \times IL$: then I is a point in the line found in the manner deſcribed in the enunciation of this propoſition.

Prop. XXXIV. *Fig.* 45.

If a ſcalene cone be cut by a plane perpendicular to the plane of the baſe, making the triangular ſection V A B; and let I E be the line found in the laſt propoſition; alſo, let the cone be cut by a plane, making an elliptical ſection, P F Q H, the *determining line* of which, M N, is parallel to the line I E; and let F H be the diameter of the ſection that is parallel to M N. Then, if M N fall between the baſe of the cone and I E, F H is the leaſt diameter of the ſection; and, if M N fall upon I E, all the diameters of the ſection are equal to F H and to one another; and if F H fall on the oppoſite ſide of I E to the baſe of the cone, F H is the greateſt diameter of the ſection.

Let R S be any diameter of the ſection different from F H, and draw V K (meeting M N in K) parallel to R S; and let K L T cut the baſe of the cone. Becauſe R S and H F are biſected in the centre G, therefore,

$RG^2 : HG^2 :: VK^2 : KL \times KT$, *Pr.* 25.

Now, if M N fall between the baſe of the cone and I E, then VK^2 is greater than $KT \times KQ$, *Pr.* 33; therefore R G is greater than H G; and, in this caſe, F H is the leaſt diameter of the ſection.

And, if M N fall upon I E, then $VK^2 = KT \times KL$; therefore $RG = HG$; and, in this caſe, the ſection is a circle.

And, laſtly, if M N be on the other ſide of I E to the baſe, then KV^2 is leſs than $KT \times KL$; therefore R G is leſs than H G; and, in this caſe, F H is the greateſt diameter of the ſection.

Cor. 1. If a ſection of a cone, not parallel to the plane of the baſe, be a circle, then I E, the line found in *Prop.* 32, is the *determining line* of that ſection.

For $RG^2 : HG^2 :: KV^2 : KT \times KL$.

And, becauſe the ſection is a circle, therefore $RG = HG$; therefore $KV^2 = KT \times KL$; therefore K is a point in the line I E, *Cor. Pr.* 25. And, in like manner, it may be ſhewn that every point of the *determining line* of the ſection is in the line I E.

Cor. 2. Let P Q be the common ſection of the plane V A B, and the plane of the ellipſe; then PQ is a diameter of the ellipſe. It is manifeſt that M N is perpendicular to the plane V A B; therefore F H, parallel to M N, is perpendicular to the ſame plane and to P Q. Alſo P Q and F H are conjugate diameters, *Pr.* 17. Therefore, when the plane V A B is perpendicular to the plane of the baſe, F H, the diameter of the ellipſe, parallel to the baſe of the cone, cuts its conjugate diameter, P Q, at right angles.

Scholium.

If F P Q H be a ſection of the cone, of which I E is the *determining line*, it is plain that P Q is parallel to V D; therefore, the angle $VQP =$ angle $BVD =$ angle V A B. Therefore, the triangle P V Q is ſimilar to the triangle B A V; but the angles at the baſe of the one triangle have a ſub-contrary poſition to the equal angles at the baſe of the other triangle. For this reaſon a ſection of a cone that has the line I E (found as in *Prop.* 32.) for its *determining line*, is called a ſub-contrary ſection.

The word ellipſe has hitherto been uſed to denote, generally, thoſe ſections of a cone which have their *determining lines* without the baſe of the cone; but, as it has been ſhewn that the conic ſection is a circle in one particular caſe (*viz.* the ſub-contrary ſection) included in this general definition, preciſion requires that the term ellipſe be hereafter reſtricted in its ſignification, ſo as to exclude that particular caſe.

Prop. XXXV. *Fig.* 46.

An ellipſe being given, it is required to draw a diameter of it that ſhall be equal to F H, the diameter which is parallel to the baſe of the cone; but the plane V A B, drawn through the vertex of the cone, and that diameter of the baſe which is perpendicular to the *determining line* of the ellipſe, muſt not be perpendicular to the plane of the baſe of the cone.

Draw the line I E, as in propoſition 32. And becauſe I E and M N are perpendicular to two different diameters of the baſe of the cone, they are not parallel: let them meet in K, and draw V K, and the diameter R S, parallel to V K; then $FH = RS$. For, becauſe R S and F H are biſected in the centre G, therefore,

$$VK^2 : KT \times KL :: FG^2 : RG^2, \text{ Pr. } 24.$$

But $VK^2 = KT \times KL$; therefore, $FG = RG$.

Cor. Only one diameter can be drawn that ſhall be equal to F H.

For, if $FH = RS$, then $VK^2 = KT \times KL$; therefore, K is in the line I E; and I E can meet M N only in one point.

Def. XXI. A diameter of a conic ſection, that cuts its ordinates at right angles, is called an axis.

Cor. Becauſe two conjugate diameters of an ellipſe, and oppoſite hyperbolas, cut their ordinates in the ſame angles, *Pr.* 24.; therefore, if theſe become axes of theſe curves, there will neceſſarily be two; and theſe will be conjugate diameters, and they will cut one another at right angles.

Prop. XXXVI. *Fig.* 47 and 48.

An ellipſe has only two axes.

Let F H (*fig.* 47.) be the diameter of the ellipſe drawn parallel to the baſe of the cone; and, firſt, let F H be the greateſt or the leaſt diameter of the ellipſe, *Pr.* 34.; then, it has already been ſhewn, that F H cuts its conjugate PQ at right angles, *Cor.* 2 *Pr.* 34.; and, therefore, F H and P Q are axes of the ellipſe, *Cor. Def.* XXI. Alſo they are the only axes of the ellipſe. For, let X Y be any other diameter, then X Y is not perpendicular to F H; draw F Z O, (cutting the ellipſe again in O) perpendicular to X Y, and draw G O. Becauſe F H is the greateſt or leaſt diameter of the ellipſe; therefore, F G is not equal to G O; therefore, F Z is not equal to Z O, 47. 1. E. Therefore F O, perpendicular to X Y, is not an ordinate of X Y; therefore, X Y is not an axis.

Secondly, when F H is not the greateſt or leaſt diameter of the ellipſe, draw the diameter R S equal to F H, *Pr.* 35.; and draw the diameter L K and D E to biſect the angles contained by F H and R S; join F S. And, becauſe L K biſects the angle at the vertex of the iſoſceles triangle F G S, it will biſect the baſe F S, and will cut it at right angles. And becauſe L K cuts F S, one of its ordinates at right angles, therefore L K is an axis; and, it is plain, that D E, parallel to F S, is another axis and the conjugate of L K. Alſo, L K and D E are the only axes of the ellipſe. For, let X Y be any other diameter; then X Y is not perpendicular both to F H and to R S; let it be not perpendicular to F H, and draw F Z O (cutting the ellipſe again in O) perpendicular to X Y, and join G O. Becauſe R S is the only diameter of the ellipſe that is equal to F H, *Cor. Pr.* 35.; therefore F G is not equal to G O; therefore F Z is not equal to ZO. And becauſe F O, perpendicular to X Y, is not an ordinate of X Y, therefore X Y is not an axis.

Prop. XXXVII. *Fig.* 49.

A hyperbola has only two axes.

Let G F and G K be the aſymptotes of the hyperbola, and draw the tranſverſe diameter G A to biſect the angle of the aſymptotes, and the ſecond diameter D E to biſect the adjacent angle; let F K, drawn between the aſymptotes, be perpendicular to G A, and meet the hyperbola in M and N. Becauſe F K is perpendicular to G L, and the angle $FGL =$ the angle K G L, therefore $FL = LK$, 26. 1. E. But $FM = NK$, *Pr.* 22.; therefore $ML = LN$. Therefore, M N perpendicular to G A, is an ordinate of G A; therefore, G A is an axis; and D E, parallel to M N, is the conjugate of G A, and another axis, *Pr.* 24.

And if G A do not biſect the angle F G K, then F K, perpendicular to G A, will not be biſected in L; therefore M L will not be equal to L N; therefore in this caſe, M N, perpendicular to G A, is not an ordinate of G A. Therefore, the hyperbola has no axes beſides G A and D E.

Prop. XXXVIII. *Fig.* 50.

A parabola has only one axis.

Let O S, terminated by the curve, be perpendicular to any diameter, and draw the diameter P Q to biſect O S; and, becauſe all the diameters of the curve are parallel, therefore, P Q is perpendicular to O S, and an axis of the curve, *Def.* XXI. And becauſe O S can be an ordinate of only one diameter, therefore there is only one axis.

Prop. XXXIX. *Fig.* 51 and 52.

The two axes of an ellipſe are always unequal; and the greater axis is the greateſt diameter, and the leſs axis the leaſt diameter of the curve. And that axis of a hyperbola, which is a tranſverſe diameter, is the leaſt of all the tranſverſe diameters.

Let A B and D E (*fig.* 51.) be the two axes of an ellipſe, C the centre, and C H any ſemidiameter; draw H P perpendicular to A B, and H Q perpendicular to D E. Becauſe A B and D E are conjugate diameters; and H P an ordinate to A B, and H Q an ordinate to D E; therefore,

$$AB^2 : DE^2 :: AP \times PB : HP^2,$$ *Cor.* 2. *Pr.* 28.

Now, if A B be ſuppoſed to be equal to D E, it will follow that $AP \times PB = HP^2$; therefore, $AP \times PB + CP^2 = HP^2 + CP^2$, or $AC^2 = CH^2$. Therefore, $AC = CH$; and the ellipſe will be a circle, which is not the caſe, *Cor.* 1. *Pr.* 33. Therefore, A B and D E are unequal; let A B be ſuppoſed to be greater than D E.

Becauſe AB^2 is greater than DE^2, therefore $AP \times PB$ is greater than HP^2; and $AP \times PB + CP^2$, or AC^2, is greater than $HP^2 + PC^2$, or CH^2. Therefore the ſemi-axis A C is greater than any other ſemi-diameter H C.

In like manner,

$$DE^2 : AB^2 :: DQ \times QE : HQ^2.$$

Therefore $DQ \times QE$ is leſs than HQ^2; and $DQ \times QE + CQ^2$, or CD^2, is leſs than $HQ^2 + CQ^2$, or CH^2. Therefore the ſemi-axis D C is leſs than any other ſemi-diameter C H.

Fig. 52. In the hyperbola, a tangent of the curve drawn from the extremity of the axis C A, as A T, falls between the centre and the curve; and becauſe C A, the ſemi-axis, is leſs than any other line drawn from C to A T, much more is it leſs than a ſemi-diameter C H drawn from C to the curve on the other ſide of A T.

Definition XXII.

The greater axis of an ellipſe is called the tranſverſe axis; and the leſs, the conjugate axis; and, in the hyperbola, that one is the tranſverſe axis which is a tranſverſe diameter, and the other is the conjugate axis.

Prop. XL. *Fig.* 51 and 52.

A diameter of an ellipſe nearer the tranſverſe axis is greater than one more remote; and a tranſverſe diameter of the hyperbola nearer the tranſverſe axis is leſs than one more remote.

Fig. 51. Let C K and C H be two ſemi-diameters of an ellipſe; join H K, and draw A G parallel to H K; join C G and draw C L to biſect H K. Becauſe C L biſects H K, it will likewiſe biſect A G, *Pr.* 15. And becauſe $AM = MG$, and A C is greater than C G, therefore the angle A M C is greater than the angle G M C, 25. 1. E; that is, the angle K L C is greater than the angle H L C. And becauſe $HL = LK$, therefore K C, nearer to C A, is greater than H C more remote from C A, 24. 1. E.

In the hyperbola, the ſame conſtruction being made, becauſe A C is leſs than C G, therefore the angle A M C, or K L C, is leſs than the angle G M C, or H L C. Therefore C K is leſs than C H.

Definitions. *Fig.* 53, 54, and 55.

XXIII. Let A B (*fig.* 53 and 54.) be the tranſverſe axis, D E the conjugate axis, and C the centre of an ellipſe, or hyperbola, or oppoſite hyperbolas; and let C F and C*f* be taken in the tranſverſe axis, ſuch that CF^2 and Cf^2 are each equal to $CA^2 - CD^2$ in the ellipſe, and to $CA^2 + CD^2$ in the hyperbola; then the two points F and *f* are called the foci of the ellipſe, hyperbola, or oppoſite hyperbolas.

Fig. 55. But the focus of a parabola is a point F in the axis, within the curve, and diſtant from the vertex by a line equal to one fourth part of the parameter of the axis.

Cor. The diſtance of each of the foci of an ellipſe from either extremity of the conjugate axis is equal to half the tranſverſe axis; and the diſtance of either of the foci of a hyperbola from the centre is equal to the diſtance between the extremities of the tranverſe and conjugate axes.

XXIV. If F (*fig.* 53 and 54.) be a focus of an ellipſe, or hyperbola, or oppoſite hyperbolas, and A G be taken in the tranſverſe axis (on the oppoſite ſide of the vertex to the focus F), ſuch, that A F is to A G as C F is to C A; then a line, as H K, drawn through G perpendicular to the tranſverſe axis, is called a directrix of the ellipſe, or hyperbola, or oppoſite hyperbolas.

Fig. 55. But the directrix of a parabola is a line, as H K, perpendicular to the axis, drawn through a point G as far diſtant from the vertex of the axis on the one ſide as the focus is on the other ſide.

Cor. An ellipſe, hyperbola, or oppoſite hyperbolas, have two directrices; one correſponding to each focus. For the ſame conſtruction that is made for one focus, may be made for the other focus.

Prop. XLI. *Fig.* 53 and 54.

Let A B be the tranſverſe, and D E the conjugate, axis of an ellipſe, or hyperbola, or oppoſite hyperbolas; from any point in the curve, or oppoſite curves, as M, let M C be drawn to the centre, and M P perpendicular to the tranſverſe axis, and take C O, in the ſame axis, ſuch that CO^2 may be equal to $MC^2 - CD^2$ in the ellipſe, and to $MC^2 + CD^2$ in the hyperbola; then as A C is to C F ſo is P C to C O.

For, becauſe A B and D E are conjugate diameters, therefore,

$AC^2 : CD^2 :: AP \times PB : MP^2$, *Cor.* 2. *Pr.* 28, therefore, $AC^2 : AC^2 \mp CD^2 :: AP \times PB : AP \times PB \mp MP^2$. But in the ellipſe $AC^2 - CD^2 = CF^2$; and $AP \times PB - MP^2 = AC^2 - CP^2 - MP^2 = AC^2 - MC^2 = AC^2 - CD^2 - CO^2 = CF^2 - CQ^2$: and, in the hyperbola, $AC^2 + CD^2 = CF^2$; and $AP \times PB + MP^2 = -PC^2 - AC^2 + MP^2 = MC^2 - AC^2 = CO^2 - CD^2 = CA^2 = CO^2 - CF^2$. Therefore, the laſt analogy becomes,

$$AC^2 : CF^2 :: AC^2 \mp CP^2 : CF^2 \mp CO^2$$

Conſequently $AC^2 : CF^2 :: CP^2 : CO^2$ 19. 5. E.

$$\text{And } AC : CF :: CP : CO.$$

Prop. XLII. *Fig.* 53 and 54.

If M be a point in an ellipſe or hyperbola, and M F and M *f* be drawn to the foci; then, in the ellipſe, the ſum of M F and M *f* is equal to the tranſverſe axis; and, in the hyperbola, the difference of M F and M *f* is equal to the tranſverſe axis.

Draw M P perpendicular to the tranſverſe axis, and take C O as in the laſt propoſition. And, becauſe

$$AC : CF :: CP : CO,$$ *Pr.* 41.

Therefore $AC \times CO = FC \times CP$; and $4\,AC \times CO = 4\,CF \times FO$. But, becauſe A B and F *f* are biſected in C, therefore $4\,AC \times CO = BO^2 - AO^2$, 8. 2. E, and $4\,FC \times CP = Pf^2 - PF^2 = fM^2 - MF^2$, 47. 1. E; therefore $BO^2 - AO^2 = fM^2 - MF^2$.

Again, $MF^2 + Mf^2 = fP^2 + FP^2 + 2\,MP^2 = 2\,FC^2 + 2\,CP^2 + 2\,MP^2 = 2\,FC^2 + 2\,MC^2 = 2\,FC^2 \pm 2\,CD^2 + 2\,CO^2 = 2\,AC^2 + 2\,CO^2 = BO^2 + AO^2$.

And, becauſe $BO^2 + AO^2 = fM^2 + MF^2$, and $BO^2 - AO^2 = fM^2 - MF^2$; therefore, by adding the equals, $2\,BO^2 = 2\,fM^2$; and, by ſubtracting the equals, $2\,MF^2 = 2\,AO^2$. Therefore $fM = BO$, and $FM = AC$; whence the propoſition is manifeſt.

PROP. XLIII. *Fig.* 53, 54, and 55.

A ſtraight line drawn from any point in a conic ſection to a focus has to a perpendicular drawn to the correſponding directrix, a ratio that is conſtantly the ſame wherever the point is aſſumed in the curve; and, in the ellipſe, the conſtant ratio is a ratio of minority (or of a leſs magnitude to a greater); in the hyperbola, the conſtant ratio is a ratio of majority (or of a greater magnitude to a leſs); and, in the parabola, the conſtant ratio is a ratio of equality.

Fig. 53 and 54. Let M be a point in an ellipſe or hyperbola, and draw MF to a focus and MK perpendicular to the directrix HG, which correſponds to that focus; draw MP perpendicular to the tranſverſe axis and take CO as in *Prop.* 41. Then

$$AC : CF :: CP : CO, \textit{ Pr. } 41.$$

Invertendo, $CF : CA :: CO : CP$

Therefore $CF : CA :: FO : AP$, 19. 5. E

But $CF : CA :: AF : AG$, *Def.* XXIV.

Therefore $CF : CA :: AO : GP$, 12. 5. E

But, as has been ſhewn in the demonſtration of the laſt propoſition, $AO = MF$, and $GP = MK$; therefore

$$CF : CA :: MF : MK.$$

But the ratio of CF to CA is a conſtant ratio; and it is a ratio of minority in the ellipſe, and a ratio of majority in the hyperbola.

Fig. 55. In the parabola, $GA = AF$, and $4\,AF \times AP = MP^2$, *Def.* XXIII.; but $4\,AF \times AP = GP^2 - PF^2$, 8. 2. E; therefore $MP^2 = GP^2 - PF^2$; and $MP^2 + PF^2$, or $MF^2 = GP^2$, or MK^2. Therefore $MF = MK$.

Moſt branches of human learning take their origin from a few detached truths, viewed at firſt without connexion, and which, in the progreſs of knowledge, are at length joined together in one body of ſcience. But when a ſcience has riſen, by accumulated diſcoveries, to ſuch a degree of importance as to intereſt the curioſity of mankind, it is often too late to retrace its hiſtory, and to delineate its riſe and progreſs in an accurate and ſatisfactory manner. It generally happens that the authors of many of the ſubordinate diſcoveries have already fallen into oblivion; and that ſome important improvements are diſputed, and aſcribed to different inventors by different writers. In reviewing the hiſtory of the conic ſections, we muſt add, to the cauſes which commonly obſcure the origin of all the ſciences, the very high antiquity of this branch of the mathematics, and the loſs of the early geometricians who have written on it. No work of antiquity that profeſſedly treats of the hiſtory of the conic ſections has reached our time; and there is little to ſatisfy curioſity in this inquiry, excepting a few incidental notices collected from different authors.

The diſcovery of the curves, denominated the conic ſections, is attributed to the philoſophers of the ſchool of Plato; and it is even aſcribed, by ſome authors, to the founder, himſelf, of that celebrated ſect. Other authors, grounding their opinion on a few words in an epigram of Eratoſthenes, have given the honour of this diſcovery to Menechmus, who lived a little poſterior to the time of Plato. But the information derived from ancient writers is too ſcanty to enable us to decide concerning the original diſcoverer of the conic ſections, or to form a well-founded judgment of the reſpective inventions of the early mathematicians whoſe works have not come down to our time. We know nothing of Ariſtæus, or Conon the friend of Archimedes, excepting that they treated of the conic ſections; and that they deſerved the commendations of ſucceeding geometricians by improving and extending the branch of ſcience which they cultivated.

It is probable that the theory of the conic ſections, like other parts of ſcience, grew up gradually from a ſmall beginning, increaſing in magnitude and importance by the ſucceſſive improvements of many geometricians. New and difficult problems would naturally lead to new artifices and inventions for their ſolution; and they would thus contribute to the extenſion of knowledge. The hiſtory of the mathematics mentions two problems, famous in ancient times, much agitated by the geometricians of the Platonic ſchool, and both of them ſo difficult as to tranſcend the limits of the ordinary, or plane, geometry. We allude to the problems of the duplication of the cube, and the triſection of an angle; and there is no doubt but that the theory of the conic ſections received great additions, and was enriched with many new properties, by the reſearches that were undertaken for reſolving theſe problems. Two ſolutions of the former problem, derived from the conic ſections, are preſerved by Eutocius, in his commentary on the works of Archimedes, which are attributed by him to Menechmus. Some ſolutions of the latter problem, by means of the conic ſections, are likewiſe extant in ancient authors, for which ſcience is probably indebted to the ingenuity of the followers of Plato.

The teſtimony of ancient authors, as well as the ſolutions of the problems which we have juſt mentioned, lead us to infer that great progreſs had been made in inveſtigating the properties of the conic ſections before the time of Archimedes. This concluſion is confirmed by the writings of that celebrated mathematician. Many principal propoſitions are there expreſsly ſaid to have been demonſtrated by preceding writers, and are ſpoken of as truths commonly divulged and known to mathematicians. Archimedes himſelf, perhaps the greateſt genius of antiquity, and deſerving to be ranked with Galileo and Newton, enriched the theory of the conic ſections with many noble diſcoveries. After a lapſe of two thouſand years, the quadrature of the parabola is ſtill the moſt remarkable inſtance, within the precincts of geometry, of the exact equality of a curvilineal to a rectilineal ſpace. To this beautiful diſcovery there muſt be added, the determining of the proportions of the elliptic ſpaces to one another, and to the circle; and likewiſe the menſuration of the ſolids generated by the revolution of the conic ſections about their axes.

But we are chiefly indebted to the preſervation of the writings of Apollonius for a more perfect knowledge of the theories of the ancient geometricians concerning the conic ſections. Apollonius was born at Perga, a town of Pamphylia, and he is ſaid to have lived under Ptolemy Philopater, about forty years poſterior to Archimedes. He was inſtructed in geometry in the ſchool of Alexandria; and, under the ſucceſſors of Euclid, he there acquired that ſuperior ſkill in the ſcience which diſtinguiſhes his writings. Beſides his great work on the conic ſections, he publiſhed many ſmaller treatiſes, relating chiefly to the geometrical analyſis, which have all periſhed, and are known to us only by the account given of them in the ſeventh book of the mathematical collections of Pappus.

The treatiſe of Apollonius on the conic ſections is written

ten in eight books, and it was eſteemed a work of ſo much merit by his contemporaries as to procure for its author the title of the great geometrician. The purpoſe of the four firſt books, as we are informed in the prefatory epiſtle to Eudemus, is to deliver the elements of the ſcience: and, in this part of his work, Apollonius profeſſes only to have collected and methodized what had already been publiſhed by former writers. One improvement introduced by him deſerves to be particularly mentioned; as it is a curious inſtance of the progreſs of the mind in generalizing its firſt conceptions. The conic ſections, according to the definitions now given of them, are ſuch curves as are produced by the common ſection of a plane and a cone of whatever kind. But the firſt mathematicians who noticed theſe curves, did not define them in a way ſo general. They confined their attention to the right cone only; and, even in this kind of cone, they always ſuppoſed the cutting plane to be perpendicular to the ſlant ſide. In this view of the matter it is manifeſt, that the ſpecies of the curve would depend on the ſort of cone by which it was produced. If the vertical angle of the cone were ſuppoſed to be an acute-angle, then the cutting plane, perpendicular to the ſlant ſide, would meet one of the conic ſurfaces only, and the line of common ſection would ſurround the whole, and would be an ellipſe. If the vertical angle of the cone were ſuppoſed to be a right-angle, then the cutting plane would ſtill meet only one of the conic ſurfaces, but the line of common ſection, not embracing the whole contour of the ſolid, would, in this caſe, be a parabola: and, laſtly, if the vertical angle of the cone were ſuppoſed to be obtuſe, then the cutting plane would interſect both the oppoſite conic ſurfaces, and the curve produced would be a hyperbola. It is true that the curves, thus defined, were rightly denominated conic ſections, conſidering them as parts of a claſs; but it did by no means follow that they comprehended all the ſpecies of the claſs. Even retaining the right cone, yet curves of a different nature might poſſibly be produced merely by varying the inclination of the cutting plane: and much more ſo, if the ſpecies of the cone, and the poſition of the cutting plane, were both changed. To Apollonius belongs the honour of having generalized the ancient definitions of the conic ſections, and of preſenting the ſubject in the more perfect form in which it ſtill continues to be taught: and the improvement is equivalent to the diſcovery that all the poſſible ſections of any cone, are reducible to three diſtinct ſpecies and no more.

Before the time of Apollonius, the names of the ſeveral conic ſections were likewiſe different from thoſe that they now bear. In conformity to the ancient definitions of the curves, the ellipſe was called the ſection of an acute-angled cone by the more early geometricians: and, in like manner, the parabola, and hyperbola, were denominated the ſections of a right-angled, and obtuſe-angled, cone. The preſent names are commonly ſuppoſed to have been invented by Apollonius; and, in compliance with the generality of writers, we have noticed the properties from which he derived them. But the received opinion on this point is probably not well founded: for both the terms, parabola and ellipſe, occur in the writings of Archimedes, which were prior to the time of Apollonius.

The four firſt books of the conics of Apollonius is the only part of that work that has come down to us in the original Greek. On the revival of learning, the lovers of the mathematics had long to regret the loſs of the original of the latter part of this important treatiſe. In the year 1658, Borelli, paſſing through Florence, found an Arabic manuſcript in the library of the Medici family, which he judged to be a tranſlation of all the eight books of the conics of Apollonius. Tranſported with joy, he had intereſt enough to prevail on the duke of Tuſcany to entruſt him with the manuſcript, which he carried to Rome: and, having procured the aſſiſtance of Abraham Ecchellenſis, a perſon ſkilled in the Arabic tongue, he publiſhed a Latin tranſlation of it in 1661. The manuſcript, diſcovered by Borelli, was entitled, "Apollonii Pergæi Libri Octo," and was ſuppoſed to be a complete tranſlation of the work of the ancient geometrician: but, on examination, it was found to contain the firſt ſeven books only. Two other Arabic tranſlations of the conics of Apollonius have been diſcovered by the induſtry of learned men: but both of them have the ſame defect as that found at Florence. From the circumſtance of all the three manuſcripts agreeing in the want of the eighth book, it is reaſonable to ſuppoſe that this part of the treatiſe had already periſhed when the tranſlations were written: and there is now no room to hope that the loſs will ever be recovered. It is not eaſy to aſcertain in what age the original of Apollonius's work diſappeared; but we know that the whole of it was extant in the time of Pappus Alexandrinus. In the "Collectiones Mathematicæ," this author has given a ſuccinct account of the contents of all the eight books, and has added the lemmas required for the demonſtrations of the propoſitions they contain: and this circumſtance enabled Dr. Halley to annex, to the complete edition of the conics of Apollonius, which he publiſhed in 1710, a reſtoration of the eighth book executed with ſo much ability as to leave little room to regret the want of the original.

In the four laſt books of his treatiſe, Apollonius, as he informs us in the prefatory epiſtle, delivers the higher and more abſtruſe parts of the theory of the conic ſections. He here claims the merit of originality, and profeſſes to develope the reſults of his own reſearches. And it muſt be confeſſed that the genius, invention, and geometrical ſkill, diſplayed in this part of his work, are ſuch as fully to juſtify the honourable appellation beſtowed on him by his contemporaries. This treatiſe muſt be allowed, even in the preſent times, to contain a very extenſive, if not a complete, theory of the conic ſections. This branch of the mathematics has, perhaps, been more cultivated than any other, ſince the revival of learning; but the induſtry of modern mathematicians has diſcovered few properties of their curves, of which ſome traces are not to be found in the work of the great geometrician. Montucla thus delivers his opinion of the treatiſe of Apollonius: "Pour donner enfin de l'ouvrage d'Apollonius l'idée qu'il mérite, je remarquerai que nous avons dans notre langue, et en ſtyle algebrique, un traité des ſections coniques dont on fait cas avec juſtice; je veux parler de celui de M. le marquis de l'Hôpital: cependant je ne craindrai point de dire qu'il y a dans le géomètre ancien un theorie bien plus ètendue et plus complete de les courbes que dans le géomètre moderne."

The mathematicians, who followed Apollonius, ſeem to have been content with the humble taſk of commenting on his treatiſe. It would be unintereſting to enumerate the crowd of commentators who, at different times, have written on his work, and have endeavoured to render it of more eaſy acceſs to the general claſs of mathematicians. Among the number we find the name of the learned Hypatia, the daughter of Theon: and we ſtill poſſeſs the lemmas of Pappus Alexandrinus for all the eight books, and the commentary of Eutocius on the four firſt books. Since the revival of learning, the theory of the conic ſections has been much cultivated, and is the ſubject of a great variety of ingenious works.

There is a relation ſubſiſting between all the parts of human knowledge, which frequently connects ſpeculations the moſt abſtracted, and ſeemingly the moſt barren, with inquiries that are highly intereſting to us, and moſt fertile in uſeful conſequences. In ſtudying the properties of the conic ſections, the followers of Plato ſought merely to gratify a contemplative turn of mind. Their reſearches were chiefly undertaken with the view of reſolving ſpeculative problems; they were directed to no immediate object of practical utility. It excites ſome degree of admiration, when we reflect that enquiries, purely intellectual, and apparently ſo little connected with external things, have, in modern times, been employed to explain many of the moſt remarkable phenomena of the material world. The doctrine of the conic ſections is equally uſeful in the ſcience of optics, and in determining the path of a projectile body. Above all, this branch of the mathematics derives its chief importance from the applications that are made of it in modern aſtronomy.

The uſes of the conic ſections in phyſical ſcience have, as it is natural to conjecture, led modern mathematicians to conſider theſe curves under particular points of view ſuited to their purpoſes. It is for this reaſon that the properties of thoſe remarkable points, called foci, have been inveſtigated with ſo much care in latter times. In optics, theſe points are almoſt excluſively the ſubjects of conſideration when the conic ſections are concerned; and, in aſtronomy, the ſun invariably occupies one of the foci of the elliptical orbits which the planets and comets deſcribe round him. Theſe points did not entirely eſcape the penetration of the ancient geometricians. Apollonius has anticipated the moderns here, as well as in other parts of this ſcience. He has unfolded many of the moſt curious properties of the foci, in the ellipſe and hyperbola. He treats of them under the appellation of "Puncta ex applicatione facta;" which ſignifies that they are points formed by cutting the tranſverſe axis in the ellipſe, and the tranſverſe axis produced in the hyperbola, into two ſegments containing a rectangle equal to the ſquare of half the leſs axis; and the phraſe is thus equivalent to the modern definitions of the ſame points. The focus of the parabola is not noticed by Apollonius, nor by any other ancient author; unleſs, indeed (as has been pointed out to the writer of this article by a friend,) we except a propoſition (Theor. 222, Prop. 238.) in the ſeventh book of the "Collectiones Mathematicæ," where Pappus delivers, in the form of a Locus, that beautiful property of the focus, and the correſponding directrix of any conic ſection, which ſome modern writers, conſidering it as characteriſtical, have made the baſis of a definition of the curves in plano. Mydorgius, contemporary with Des Cartes, is the firſt who treated generally of the foci, of all the conic ſections. Since his time the properties of theſe points have been gradually and fully developed.

Before Dr. Wallis, all the writers on conic ſections followed the ancient geometricians in making the cone the common origin and foundation of their theories. That mathematician firſt entertained the idea of uſing the cone as little as poſſible in delivering the elements of the conic geometry; and this plan is purſued in his treatiſe, publiſhed at Oxford in 1655. In ſupport of this innovation, Dr. Wallis urges the prolixity of Apollonius's work, and the difficulty and perplexed nature of the demonſtrations. On the old plan, many propoſitions reſpecting the generating of the cone, and the properties of that ſolid, are to be previouſly gone through; and the diagrams are rendered confuſed by many lines drawn in different planes. On theſe accounts, he aſſerts, that the ſtudy of the conic ſections was generally neglected: "unde et nimis neglecta fuit (conicorum doctrina), tanquam inſuperabilis difficultatis plena." It muſt be allowed that the objections of Dr. Wallis are not without foundation. On the other hand, it has been the opinion of ſome later mathematicians, that the defects of the treatiſe of Apollonius ariſe, not from his having made too much uſe of the cone, but from his having availed himſelf too little of the aſſiſtance to be derived from that ſolid. They contend that the moſt general and characteriſtical properties are firſt to be ſought for in the cone itſelf; whence they are to be transferred to its ſections, as particular caſes of more general propoſitions. The lateſt, and moſt approved writers, who have adopted this opinion, are Dr. Hamilton and profeſſor Robertſon of Oxford. Although Dr. Wallis propoſed to introduce the cone as little as poſſible in delivering the elements of the conic geometry; yet it is to be remarked that he ſtill imitated his predeceſſors in deriving, from that ſolid, the fundamental property which he afterwards made the baſis of all his reaſonings. But the idea, which he introduced, was ſoon carried farther; and treatiſes on the conic ſections were written, in which the cone was entirely laid aſide, and the curves were defined from deſcriptions in plano. De la Hire, in his "Nouveaux Elemens des Sections Coniques," publiſhed at Paris in 1679, is the firſt author who ſucceſsfully treated on the conic ſections in this new view of the ſubject. He derives the deſcription of the parabola from the equality that ſubſiſts between two lines meeting in any point of the curve, one of which is drawn to the focus, and the other is perpendicular to the directrix; and he deſcribes the ellipſe and hyperbola from the analogous properties, that, in the one, the ſum of two lines drawn from any point in the curve to the two foci, and, in the other, the difference of two ſuch lines, are equal to the tranſverſe axes. In theſe fundamental points De la Hire is followed by moſt of the later writers, who have treated of the conic ſections independently of the cone; and, in particular, by Dr. Simſon of Glaſgow, who has publiſhed an extenſive and accurate treatiſe on this ſubject. Beſides the method of De la Hire, another way of defining the curves in plano has been propoſed. It is founded on that general property of the directrix firſt given by Pappus Alexandrinus, as we have already noticed above. The learned abbé Boſcovich, an excellent Italian mathematician, has drawn his definitions of the curves from this fundamental property in the ingenious treatiſe on conic ſections, publiſhed in his "Elementa Matheſeos Univerſæ:" and we have two works in our own language, which are founded on the ſame primary definitions; that of Mr. Newton of Cambridge, and that of Mr. Walker of Nottingham.

The doctrine of the conic ſections is of great uſe in phyſical and geometrical aſtronomy, and the phyſico-mathematical ſciences. This doctrine has been much cultivated by geometers ancient and modern: and we have many good treatiſes on the ſubject; but that publiſhed by Mr. Simſon, profeſſor of mathematics at Glaſgow, deſerves to be particularly mentioned, not only for its elegance, but for its geometrical accuracy, which, as he juſtly remarks in his preface, has not always been ſo well obſerved in treatiſes of this kind, as it ought to be. See alſo Gregorii a St. Vincenti Opus de Quadratura Circuli, & Sectionum Coni; Mydorgius de Sectionibus Conicis: De la Hire de Sectionibus Conicis; Trevigar Elem. Section. Con.; Hamilton's Tract. Geom. de Section. Con.; De l'Hopital's Anal. Treat. of Conic Sections; Muller's Treatiſe, &c.; Hutton's; and Halley's edition of Apollonius, &c. Oxon. 1710. fol.

To the properties of the conic ſections, mentioned above, it may be proper to add the properties of their oſculatory circles, or circles of curvature. See CURVATURE.

CONIC *ſections, ſimilar*. See SIMILAR.

CONIC *Form of Mountains and Hills*. Too many naturaliſts have fallen into the miſtake, of denominating mountains or hills which have a conical top, to be of volcanic origin; becauſe, granite ſometimes, as Achterman mountain in the Hartz, aſſumes a conic form, Laſius 17; and porphyry frequently takes this ſhape. In ſome rare inſtances, the rupture of the ſtrata has produced conical hills. See ELEVATION *of Strata* and VOLCANO.

CONICA, in *Ancient Geography*, a town of Aſia, in Paphlagonia. Ptolemy.

CONICS, that part of the higher geometry, or geometry of curves, which conſiders the cone, and the ſeveral curve lines ariſing from the ſections thereof.

CONICTHYODONTES, or *Plectronitæ*, in *Natural Hiſtory*, one of the three names by which the foſſil teeth of fiſh are known; ſo called, from their ſuppoſed reſemblance to the ſpur of a fighting cock.

Though authors aſſure us that theſe are the teeth of a fiſh, the jaws having been found with theſe bodies in them; yet they do not pretend to know to what fiſh they belong. They are generally of an oblong conic figure, broad at the baſe, and narrow at the point, where they are uſually a little crooked: they are hollowed at the root, and are from the tenth of an inch to two inches long, commonly of a cheſnut colour, and are found in the ſtrata of clay, but moſt uſually in thoſe of ſtone; and are ſeen more frequently in England than in any other part of the world. Hill's Foſſils, p. 645.

CONJECTURE, in the *Philoſophy of the Mind*, expreſſes a degree of belief founded upon ſlight evidence. In ſome caſes, a diſpoſition to conjecture, indiſcreetly indulged, may be productive of many extravagancies. It may prompt us to build favourite hypotheſes on very weak foundations, and to aſcribe the conduct of others to wrong motives, according to our prejudices for or againſt them. When indulged with diſcretion, a conjecture affords ſome relief to the mind from the inquietude of ignorance and uncertainty. It provides a temporary ſubſtitute for knowledge; and it frequently ſuggeſts ideas which lead to the diſcovery of truth.

Conjectural criticiſm, and conſequent emendations of ancient authors, claſſical and ſcriptural, ſhould be exerciſed with great caution; otherwiſe, the imagination will be apt to miſlead perſons moſt eminent for their genius and learning.

It is one of the moſt important, and at the ſame time one of the moſt diſputed points in ſound criticiſm, ſays Michaelis, whether what is called "conjectura critica," may be applied to the New Teſtament; or, in other words, whether in certain caſes, and under certain reſtriction, provided we uſe all due care and caution, we may reject the readings of all the MSS., verſions, and fathers, and merely on a probable ſuppoſition, admit a reading that is ſupported by no written authority; and whether, if we proceed on theſe principles, we have any reaſon to expect, that we ſhall ever arrive at the truth. Many learned men, deſervedly eſteemed critics, are of opinion, that conjectures are as allowable at preſent in the New Teſtament, as in the claſſic authors. Nevertheleſs, the majority of divines formerly conſidered them as preſumptuous, if not impious; but thoſe perſons who are ſo ſtrenuouſly attached to the printed text, are not aware, as Wetſtein obſerves, in his Prolegomena, that a very great number of readings, which they ſo zealouſly ſupport, are merely critical conjectures, advanced either by the ancient fathers, or by the modern editors of the Greek Teſtament, in the 16th and 17th centuries. Theſe readings muſt therefore be immediately rejected, if critical conjecture is wholly inadmiſſible. As this queſtion is purely critical, it ſhould be argued, not on theological, but on critical grounds. The argument which is drawn from the hypotheſis, that Divine Providence would not permit the true reading in any text of the New Teſtament to be loſt, ſeems to be very extraordinary, when it is urged by perſons who tacitly acknowledge that the ſame providence has not guarded againſt the neceſſity of conjecture in the Old Teſtament. Beſides, no man can aſſert, that, becauſe the true reading of any paſſage is no longer to be found, it is therefore totally loſt, ſince the number of MSS. of the Greek Teſtament (together with other original documents) which have been actually collated, are trifling in compariſon with the whole number that have been written; and a reading, which is now ſupported only by probable conjecture, may, in proceſs of time, be confirmed by good authority. Moreover, it by no means diminiſhes the certainty of our faith, that ſome few paſſages of the New Teſtament have certain internal marks, which diſcover them to be not genuine, and which render it neceſſary to reſtore the true reading by critical conjecture. Our faith would only be in danger, if the number of theſe paſſages was ſo very great, as to render the whole New Teſtament ſuſpicious; or, if the principal and diſtinguiſhing doctrines of Chriſtianity muſt be either added to, or taken from, the ſacred text, on no other authority than that of mere conjecture. But if, without aſſuming to ourſelves the power of altering articles of religion, and confining our emendations to mere matters of criticiſm, we alter ſome words or ſentences, the grounds of our faith are by no means affected, nor need we apprehend any evil conſequences. In ancient writings, of which only one copy is extant, critical conjecture is indiſpenſable. The neceſſity remains the ſame, even where there are ſeveral MSS. if thoſe MSS. are only copies of one and the ſame more ancient MS. If we have more than a ſingle copy of any work, and thoſe copies are tranſcripts of different and diſtinct MSS., the neceſſity of critical conjecture decreaſes in proportion to the number of copies; but it does not entirely vaniſh, unleſs the number of the MSS. is very conſiderable. We have, therefore, no reaſon for cenſuring the critics of the 16th century, if, in their editions of the Greek Teſtament, they have ſometimes, departed from the reading of their MSS., and ſubſtituted ſuch as were agreeable to probable conjecture. The probability, however, that critical conjecture alone can reſtore the true reading, decreaſes in the ſame proportion, as our materials of criticiſm, or collections of various readings increaſe. And ſince ſo many MSS., works of the fathers, and ancient verſions made in diſtant countries, and in different periods, have been carefully collated; and ſince alſo thoſe very ancient Latin verſions that vary ſo conſiderably from each other, and were tranſlated from very different Greek MSS. have been made known to the public, we might even doubt whether critical conjecture ought not at preſent to be entirely rejected. It has, however, its learned and zealous advocates. It deſerves to be conſidered, in reply to the plauſible objection above ſuggeſted, that we have not a ſingle MS. now extant, that was written in the four firſt centuries, and that the ancient verſions have not deſcended to us without alterations. It is likewiſe evident, from the writings of the fathers, that many readings were in thoſe times in the Greek MSS., which are not now found in any, or only in a very few; having been altered either by accident, or becauſe they appeared to the tranſcribers to be obſcure, or exceptionable.

ceptionable. It is therefore not impoſſible, that other readings, which have not been preſerved in the works of the fathers, or in the Greek MSS., may have been equally loſt; and among them, perhaps, ſome that were genuine. Beſides, it is not impoſſible that there are many important MSS. of which we have no knowledge; and that a collation of thoſe MSS. might confirm the critical conjectures of the 18th century, in the ſame manner as many conjectures of the 16th century have been confirmed in the 18th, by the authority of MSS., and ancient verſions. It might further be added, and it deſerves conſideration, that all our MSS., and verſions of the New Teſtament, were probably taken, not from the ſingle copies of the Goſpels and Epiſtles, which proceeded from the hands of the Apoſtles themſelves, but from the collection that was formed of the ſeveral parts of the New Teſtament. If, inſtead of 292 MSS. enumerated by Michaelis, we had above 1000, they would ſtill be tranſcripts of one and the ſame copy; and if this copy had any errors, which it would be the higheſt preſumption to deny, theſe errors muſt have been tranſmitted into every MS. of the Greek Teſtament, whatſoever; and theſe errors can be remedied only by the aid of critical conjecture. Upon the whole, it appears, that a collection of critical conjectures may be of great uſe in eſtabliſhing the genuine text of the Greek Teſtament; and it is likewiſe attended with this particular advantage, that we are led by it to examine MSS., and other original documents, with greater accuracy, in order to ſee whether thoſe readings, which had no other ſupport than conjecture, may not be eſtabliſhed by written authority. Such a collection has been publiſhed by Bowyer, a learned bookſeller in London, the third edition of which, with improvements, was publiſhed in London in 1782. Of ſeveral hundred conjectures, which Bowyer has produced, there is hardly one, ſays Michaelis, which, after impartial examination, will be found probable. On the other hand, it cannot be denied, that there are ſome few, which bear on them the marks of probability. Several of theſe are examined by Michaelis, and he has added a variety of his own conjectures, for which we muſt refer to his work, cited at the cloſe of this article. Beſides the critical conjectures already mentioned, there is another kind of conjecture, denominated by Michaelis "theological conjecture," which conſiſts in altering the text of the ſacred writings, according to the maxims adopted by any particular party, whether it be the ruling, or the perſecuted party, in the church. Although it is allowable to venture a conjecture in matters relating to hiſtory, to dates, or to names, as in theſe caſes the Bible is not our only "principium cognoſcendi," yet whoever alters the text in ſubjects which relate to points of divinity, evidently preſuppoſes a "principium cognoſcendi," that is prior to the Bible itſelf; and this is frequently nothing more than a ſet of principles, which this or that particular perſon has thought proper to adopt. It has been urged by thoſe who defend theological conjecture, that we ought never to loſe ſight of the "analogia fidei," or analogy of faith. Thus, if two paſſages in the Bible contradict each other in matters of faith, the one muſt be altered. But the queſtion recurs, how ſhall we determine which of the two is to be altered? "In my opinion," ſays Michaelis, "we ſhould alter neither, but reject the whole, as not coming from the Deity, if it be true that there are real contradictions, for it is upon this ground, that we condemn the Koran." But every apparent contradiction is not a contradiction in reality; and paſſages that are ſeemingly at variance may, with ſkill and patience, be reconciled. Such is the caſe with reſpect to Rom. iii. 28. and James, ii. 24. the whole contradiction vaniſhing, as ſoon as we reflect that St. Paul underſtands faith in Chriſt, St. James faith in the unity of the Godhead. For other obſervations on this ſubject, we refer to the author. Michaelis's Introduction to the New Teſtament by Marſh, vol. ii. part. 1. See CRITICISM.

CONIFERÆ, in *Botany*, the fifteenth natural order in the Philoſophia Botanica of Linnæus, and the fifty-firſt of the Prælections. In the Philoſophia Botanica the genera included in it are abies, pinus, cupreſſus, thuja, juniperus, taxus, ephedra. Theſe are all retained in the Prælections, pinus and abies being united, and equiſetum added with a mark of doubt, and an obſervation that it has the pollen of filix. The order derives its name from the cones or ſtrobiles in which the ſeeds are contained. The fruit of juniperus, indeed, ſeems to be a berry, but it is properly a ſtrobile, with pulpy ſcales, which do not open; for it has ſix fleſhy connate ſcales, each containing a ſingle ſeed. Taxus alſo apparently bears a berry; but this falſe berry is only the fleſhy receptacle almoſt covering the ſeed. All the coniferæ yield a reſin, which renders moſt of them evergreen. The fruit in all is biennial, produced in the ſpring, but not ripening and dropping its ſeeds until the ſpring after.

The coniferæ compoſe alſo one of the natural orders of Juſſieu, the fifth of his fifteenth claſs, with the following character: *Flowers* monoicous or dioicous. *Males* moſt frequently in a catkin, or heaped together upon a catkin, each furniſhed with a ſcale, with or without a calyx: the ſtamens attached either to the calyx, or to the ſcale. *Stamens* definite or indefinite in number: filaments ſometimes diſtinct, ſometimes united into a ſimple or branched ſtipes. *Females* either ſolitary, or capitate, or diſpoſed in a ſtrobile or cone, denſely imbricated with ſcales that ſeparate the flowers; furniſhed either with a calyx or with a ſcale diſcharging the office of a calyx. *Germ* ſuperior, conical, either double or manifold, with as many ſtyles and ſtigmas, and either as many ſeeds, or as many one-ſeeded capſules. *Corculum* cylindrical, central, in a fleſhy periſperm, two-lobed; the lobes ſometimes, but rarely, divided or palmate, thence appearing many-lobed. *Stem* a tree or ſhrub. It contains the following genera: I. With a ſtaminiferous calyx; ephedra, caſuarina, taxus. II. With only a ſtaminiferous ſcale, the true coniferæ: Juniperus, cupreſſus, thuya, araucaria (Dom. beya: Lam.), pinus, abies.

Ventenat has the ſame diviſion and genera, except that he omits araucaria.

CONIGLIANO, in *Geography*, a ſmall, but populous, town, in the diſtrict of Treviſo, in the territory of Venice, which now forms part of the kingdom of Italy.

CONIL, a ſmall town of Spain, in the kingdom of Seville, in Andaluſia, on a bay to which it gives name; 15 miles S.S.E. from Cadiz, with a ſtrong caſtle. Its inhabitants ſubſiſt chiefly by fiſhing. N. lat. 36° 16.′ W. long. 6° 8′.

CONIMBRIGA, or CONIMBRICA, in *Ancient Geography*, *Coimbre*, a town of Spain, in Luſitania, on the Munda.

CONIN, or KONIN, in *Geography*, a town of Poland, in the palatinate of Kaliſch; 18 miles S.S.E. of Gneſen.

CONJOINED, or CONJUNCT, in *Heraldry*, a term uſed for charges in arms when linked together.

CONJOINT, or CONJUNCT, is applied in *Ancient Muſic*, in the ſame ſenſe as *conſonant*, to two or more ſounds heard at the ſame time. See CONSONANCE.

CONJOINT *degrees*, two notes which immediately follow each other in the order of the ſcale; as *ut* and *re*.

CONJOINT *tetrachords*, are two tetrachords, where the ſame *chord* is the higheſt of the one, and the loweſt of the other.

CONIQUE, *Fr.* This term is applied to a piece of artillery, of which the bore is wider towards the muzzle than it is towards the breech.

CONIRA, in *Botany*, a name uſed by ſome authors for the *myrrhis*. Ger. Emac. Ind 2.

CONISALUS, in *Mythology*, a god of the Athenians mentioned by Strabo, and ſuppoſed to be the ſame with Priapus.

CONISBERG, in *Geography*. See KONGSBERG.

CONISCI, in *Ancient Geography*, a people of Spain, who formed a part of the Cantabri, and in their dreſs reſembled the Gauls, according to Strabo.

CONISIUM, a town of Aſia, in Myſia, according to Pliny. Hierocles calls it *Cinioſine*, and makes it an epiſcopal city in the province of the Helleſpont.

CONISOR. See GOGNISOR.

CONISSALÆ, in *Natural Hiſtory*, the name of a claſs of foſſil bodies; the word is derived from κονισσαλος, *powder;* all the ſpecies of bodies of this claſs being found like common ſand; in form of powder, have been uſually confounded together, under the common name of *ſands*. The coniſſalæ are defined to be ſtones of a differently debaſed, cryſtalline, or ſparry matter, but always found in form of ſmall and diſunited particles, great numbers of which, being amaſſed together, form a kind of powder.

Of this claſs of bodies there are two diſtinct and large genera. 1. The ſands properly ſo called, which are compoſed of particles all appearing to have a tendency to the ſame regular figures, tranſparent, vitrifiable by a ſtrong fire, and not ſoluble in, or effervefcing with acids. 2. The *ſaburræ*, or *grit*, of ſtone found looſe; theſe are found in form of powder, the particles of which, in general, have no tendency to any particular figure, but appear to be rudely broken fragments of larger maſſes. Hill's Hiſt. of Foſſ. p. 543.

CONISTERIUM, a room in the ancient Gymnaſia or Paleſtræ, in which was kept the ſand for the uſe of the wreſtlers, who were accuſtomed, after anointing their bodies with oil, to ſprinkle themſelves with ſand to afford a firmer graſp in their encounters.

CONISTON, in *Geography*, a village in the northern part of Lancaſhire, in the hundred of Loynſdale. Latitude about 54° 29′, and longitude 2° 44′. W. It is ſituate on the ſteep aſcent of a mountain of blue argillaceous ſchiſtus, near the northern end of a romantic lake, of ſix miles in length, and one in breadth, called after its name; near this town ſome copper-mines are worked, but to no conſiderable extent, and ſome veins of lead-ore: ſlate quarries are alſo to be found near this place. There is a torrent or mountain ſtream of water which precipitates itſelf into the lake near this place.

CONISTORSIS, in *Ancient Geography*, a town of Spain in Celtiberia. Strabo mentions it as a very famous town.

CONITZ, or CHOINITZ, in *Geography*, a town of Pruſſia, in Pomerelia; 40 miles S. of Dantzick.

CONJUGAL RIGHTS, in *Law*. The ſuit for "reſtitution of conjugal rights" is one ſpecies of matrimonial cauſes; which is brought whenever the huſband or wife is guilty of "ſubtraction," or lives ſeparate from the other without any ſufficient reaſon: in which caſe the eccleſiaſtical juriſdiction will compel them to come together again, if either party be weak enough to deſire it, contrary to the inclination of the other.

CONJUGATE *Axis*, &c. in *Conics*. See CONIC *Sections*.

CONJUGATE *Point*, in *Geometry*. See POINT.

CONJUGATES, in *Rhetoric*, denote words deduced from the ſame origin with that of the ſubject: *e. g. He who does juſtly, is juſt.*

CONJUGATION, in *Anatomy*, a term applied by the older anatomiſts to the nerves coming from the brain, in the ſame ſenſe that we employ the expreſſion, pair of nerves.

CONJUGATION, in *Grammar*, an orderly diſtribution of the ſeveral parts or inflexions of verbs, in their different moods and tenſes, to diſtinguiſh them from each other: or, the manner in which the perſonal terminations of verbs are changed to expreſs the ſeveral moods and tenſes.

The Latins have four conjugations diſtinguiſhed by the terminations of the infinitive, *are, ēre, ĕre, ire;* and moſt of the French grammarians reduce the conjugations of their language to the ſame number, ending in *er, re, ir*, and *oir*. Some have added a fifth Latin conjugation called the *mixt*, becauſe it is compoſed of the third and fourth, as *capio, accipio*.

The Greeks have three kinds of verbs; the firſt called *barytons*, becauſe the laſt ſyllable is pronounced with a grave accent; (ſee BARYTONUM); ſuch are τεινω, *tendo*, and τυπτω, *verbero:* the ſecond are circumflex verbs, which admit a contraction in their termination, and are then marked with a circumflex accent; ſuch is αγαπαω, αγαπω, *amo:* the third kind comprehends the verbs in μι, as ειμι, *ſum*. Of the firſt ſort there are ſix conjugations; divided according to their characteriſtic, *i. e.* the letter preceding the termination. Accordingly verbs having the labials π, β, φ, or πτ, form the firſt conjugation of barytons; thoſe having the gutturals κ, γ, χ, or κτ, the ſecond; thoſe having the dentals τ, δ, θ form the third; verbs in ζω, σσω, or ττω, comprehend the fourth conjugation; the liquids λ, μ, ν, ρ, mark the fifth; while thoſe in ω pure, ſuch as τιω, λυω, diſtinguiſh the ſixth conjugation. Of the ſecond there are three, *viz.* thoſe in αω, εω, οω: but all theſe and the barytonous verbs are conjugated, that is, are varied in the ſame way to expreſs mood, time, number, and perſon. Of the third, there are four. But Meſſrs. de Port Royal reduce theſe 13 conjugations to two: *viz.* one in ω, comprehending the barytons and circumflex verbs; and the other thoſe in μι.

Mr. I. Jones, in his "Grammar of the Greek Tongue, on a new and improved Plan," has judiciouſly rejected the fore-mentioned diſtinctions as unneceſſary, becauſe they are uſeleſs and unmeaning; and diſtributed the Greek conjugations into four; *viz.* the active ω, its paſſive ομαι, the active μι, and its paſſive μαι.

In the Hebrew language there are four conjugations, *viz.* *kal* with its paſſive *niphal, pihel* with its paſſive *pyhal*, to which alſo may be referred *pohel, hiphil* with its paſſive *hophal*, and *hithpahel*. The third perſon ſingular maſculine of the firſt conjugation is the preterite of the theme; the ſecond conjugation has a *dageſh forte* in the ſecond radical; the third has the prefix letter ה; and the fourth, the ſyllable הת.

In Engliſh, where the verbs have ſcarce any natural inflexions, but derive all their variations from additional particles, pronouns, &c. we have hardly any ſuch thing as ſtrict conjugations.

Some grammarians, however, diſtribute Engliſh verbs into three conjugations, or claſſes, diſtinguiſhed from one another by a peculiar formation in ſome principal part belonging to each: and they obſerve that the three different terminations of the participles, *viz. ed*, or its contraction *t*, *ght*, and *en*, may be conſidered as the characteriſtics of the conjugations. But as the verbs of the firſt conjugation would ſo greatly exceed in number thoſe of both the others; and as thoſe of the third conjugation are ſo various in their form, and incapable of being reduced to one plain rule; it ſeems better in practice, as biſhop Lowth juſtly obſerves, to conſider the firſt in *ed* as the only regular form, and the others as deviations from it: after the example of the Saxon and German grammarians. Lowth's Introd. to Engliſh Grammar, p. 104, 1772. Murray's Eng. Gram. p. 96. ed. 8. Others again diſtinguiſh them by the different inflexion of the firſt tenſe in each root, and thus make four conjugations in the active voice: the firſt has three radicals alike: as *I do read; I read; i. e.* yeſterday; *I have read, i. e.* juſt now. The ſecond has the firſt and third radical alike; as *I run, I ran, I have run.* The third conjugation has the ſecond and third radical alike; as *I eſteem, I eſteemed, I have eſteemed.* The fourth has the three radicals different; as *I write, I wrote, I have written* or *writ.* The paſſive voice, being made up of the third radical and the auxiliary verb *am*, admits of no difference of conjugations. Ward's Eſſays on the Engliſh Language, p. 87.

CONIUM, in *Botany*, (κωνειον; Theophraſt. Dioſc. derived by Henry Stephens from κωνος, the cone of the mathematicians, a name given alſo, on account of its form, to that well-known children's toy, a top. From this latter ſenſe came the verb κωναω, which Heſychius explains by περιδινῶ implying a capacity to produce a whirling motion; and thence the poiſonous herb employed by the Greeks as the means of inflicting a capital puniſhment, was called κωνειον, becauſe it occaſioned a ſenſation of giddineſs in the ſufferer. Linnæus unaccountably derives the word from κονια, *duſt*). Linn. Gen. 336. Schreb. 469. Willd. 53. (Cicuta. Tourn. 160. Hall. 766. Gært. 117. Lam. Ill. 503. Juſſ. 223. Vent. 3. 28. Ciguë. Lam. Enc.) Claſs and order, *pentandria digynia.* Nat. Ord. *Umbellatæ*; Linn. *Umbelliferæ*; Juſſ. Vent.

Gen. Ch. *Umbel* partial, and univerſal with many ſpreading rays. *Involucre univerſal*, three or many-leaved, ſhort, unequal, membranous towards the baſe: *partial* with about three leaves, only half encloſing the pedicels. *Cal.* ſcarcely perceptible. *Cor.* Petals five, inflexed, heart-ſhaped, unequal. *Stam.* Filaments five, about the length of the petals; anthers roundiſh. *Piſt.* Germ inferior; ſtyles two, ſhort, reflexed; ſtigmas obtuſe. *Peric.* none. *Fruit* nearly globular, with five crenulate ridges; compoſed of two *ſeeds*, which are convex, almoſt hemiſpherical, ſtriated on one ſide, flat on the other, ſeparating as they become ripe.

Eſſ. Ch. Partial involucre only on one ſide, about three-leaved. Fruit nearly globular, with fine crenulate ridges.

Sp. 1. C. *maculatum.* Common hemlock. Linn. Sp. Pl. 1. Mart. 1. Willd. 1. Jacq. Auſt. 2. tab. 156. Curt. Flor. Lond. 1. tab. 17. Eng. Bot. 1191. Woodv. Med. Bot. tab. 22. (Cicuta major; Lam. Ill. tab. 195. fig. 1. Bauh. Pin. 160. Rai. Syn. Cicuta domeſtica. Moriſ. Umb. 18 *c. b.* § 9. tab. 6. fig. 1. Coriandrum. Roth Cranz.) "Seeds ſtriated." Linn. "Stem ſpotted at the baſe; furrows of the ſeeds crenate." Lam. "Seeds without prickles; ſtem much branched, ſhining, ſtriated." Dr. Smith. *Root* biennial, ſpindle-ſhaped, often branched, white, fleſhy. *Stem* three or four feet high, erect, cylindrical, hollow, furrowed, ſmooth, ſhining, marked with purple ſpots, much branched, eſpecially towards the top, leafy. *Leaves* ſupra-decompound, or ſeveral times pinnated; bottom ones very large, ſometimes two feet long; leaflets oblong, acutely notched, dark green above, paler underneath. *Rays* of the *umbel* from ten to twelve; of the umbellule fifteen or ſixteen. General involucre commonly many-leaved, deflexed. *Petals* white, heart-ſhaped, inflexed, nearly equal. The whole plant is narcotic, with a diſagreeable ſmell and nauſeous taſte. Very different opinions have been entertained with reſpect to its active qualities, but it may be doubted whether authors have always intended the ſame plant. Haller was inclined to think, that the plant which was fatal to Socrates and Phocion, was not that now before us, but the cicuta viroſa of Linnæus, which the French writers have called cicutaria. La Marck, on the other hand, aſſerts that the conium maculatum of Linnæus, his cicuta magna, is the cicuta of ancient authors, the very plant by which Socrates was poiſoned; and ſeverely cenſures Linnæus for changing its name to conium. But if this great botaniſt had looked into the Greek authors, he would have found that Linnæus only reſtored the moſt ancient name, and that the word cicuta is entirely of Latin origin, unknown to the Greek language. Whether Linnæus would not have done better, if he had retained the term cicuta, which had been adopted by all the modern botaniſts before him, is a queſtion to which an affirmative anſwer may perhaps be given. His cicuta viroſa might then, in concurrence with Haller's opinion, have been called conium. But when the change was made and had, through the extenſive circulation of the works of Linnæus, obtained general currency, a revival of the ancient name, inſtead of removing, has, in fact, increaſed the confuſion. Whatever may have been the plant by which Socrates was judicially murdered, our conium maculatum unqueſtionably poſſeſſes deleterious qualities; but, as Dr. Smith obſerves, it is happily too nauſeous to be incautiouſly ſwallowed in any dangerous quantity. See CICUTA in the Materia Medica, where it ſhould have been obſerved that Plato does not call the plant, by which Socrates periſhed, cicuta, a word which he had never heard; nor does he give it any Greek name peculiar to it; but conſtantly uſes the very general term φαρμακον, which denotes a ſtrong potion either poiſonous or medicinal. 2. C. *rugoſum.* Willd. 2. Thunb. prod. 50. (C. ſuffruticoſum; Berg. cap. 77.) "Seeds wrinkled." *Stem* ſomewhat ſhrubby. A native of the Cape of Good Hope. 3. C. *rigens.* Linn. Mant. 56. Mart. 2. Lam. 2. Willd. 3. Thunb. prod. 50. "Seeds ſomewhat muricated; peduncles furrowed; leaflets channelled, obtuſe." *Root* perennial. *Stem* purpliſh, rigid, ſtriated, erect, diffuſe, branched. *Leaves* twice-winged, ſomewhat fleſhy, doubled, obtuſe, crenulate, hard, the colour of rue; petioles longitudinally channelled. *Florets* all fertile, white; leaflets of the general involucre five, ſhorter than the rays of the umbel; one or two divided; thoſe of the little umbels ſeven; a few of them crenate; petals equal, lanceolate, rolled inwards. *Seeds* reddiſh, ſtriated and ſomewhat muricated. A native of the Cape of Good Hope, on the coaſt, introduced into England in 1787, by Maſſon. 4. C. *africanum.* Linn. Sp. Pl. 2. Mart. 3. Willd. 4. Jacq. hort. tab. 194. (Cicuta africana; Lam. 3. Ill. tab. 195. fig. 2. Caucalis africana; Boerh. Lugd. b. 1. tab. 63. Capnophyllum; Gært. 2. tab. 85. fig. 6.) "Seeds prickly." Linn. "Seeds muricated; petioles and peduncles even-ſurfaced." Willd. "Leaves twice winged, glaucous; petioles and peduncles even-ſurfaced; ſeeds tooth-muricated." Lam. *Root* annual, *Stems* three or four inches long, herbaceous, cylindrical, ſmooth, glaucous; with a few leaves, and one or two ſhort axillary branches. *Root-leaves* almoſt as long as the ſtem; leaflets flat, not channelled, ſmall, gaſhed. *Flowers* white, almoſt regular, in ſmall terminal umbels; leaflets of the general involucre from three to five, membranous towards the baſe; ſeveral of the florets barren. *Fruit* in the centre, ſeſſile. Linn. *Fruit* elliptical, lenticularly compreſſed, ſolitary in the centre of the partial umbels, nearly ſeſſile. *Seeds* ſlightly convex on one ſide, with three, ſometimes only two, tubercled or tooth-muricated ribs; flat or a little concave on the other; marked with a longitudinal middle line, and two curved, nearly obſolete, lateral ones. Gært. A native of the Cape of Good Hope; cultivated in 1759 by Miller, who received the ſeeds from Boerhaave. 5. C. *tenuifolium.* Mart. 5. Vahl. Symb. 3. 49. "Root and ſtem-leaves ſimple, linear." *Stem* a foot high, herbaceous, upright, ſcarcely branched, ſlender, cylindrical, ſmooth, ſlightly ſtriated. *Leaves* very narrow, a little broader at the baſe, ſomewhat ſheathing, very ſmooth; lower ones about four inches long. *Peduncles* lateral and terminal, few, remote. *General involucre* five-leaved; leaflets awl-ſhaped, ſomewhat rigid, ſhorter than the umbel; *partial* ones the length of the little umbels. *General umbel* ſmall, five-rayed; partial ones eight or ten-flowered. *Seeds* oblong, ſtriated, ſmall, ſmooth. A native of the Cape of Good Hope.

Conium *Royeni.* Linn. See Caucalis *arvenſis.*

Conium *dichotomum.* Desfont. See Tordylium *peregrinum.*

Conium, in *Ancient Geography*, a town of Aſia Minor, in Pacatian Phrygia. It appears to have been founded by Cineas, king of Theſſaly; and according to the notitia of Hierocles, it had been epiſcopal.

CONJUNCT. See Conjoint Pair.

Conjunct *of an arch.* See Supplement.

Conjunct *ſentence.* See Sentence.

CONJUNCTION, in *Aſtronomy*, the meeting of the ſtars or planets, in the ſame point or place of the heavens, and it is either *true* or *apparent.*

If the two bodies meet both in the ſame degree of longitude and latitude, a right line drawn from the centre of the earth through the centre of one of them, paſſes through that of the other; then the conjunction is ſaid to be true and central: and if the lower hides the upper, the conjunction is ſaid to be corporal.

If the line paſs wide of the centre of the earth, the conjunction is ſaid to be partile.

If the bodies do not meet preciſely in the ſame degree, but are joined with ſome latitude, the conjunction is ſaid to be apparent. Thus, when a right line, ſuppoſed to be drawn through the centres of two planets, does not paſs through the centre of the earth, but through the eye of the ſpectator; it is ſaid to be an apparent conjunction.

Some have alſo divided conjunctions into *great* and *greateſt:* the former denoting thoſe which occur at comparatively a ſhorter interval, ſuch as the conjunctions of Jupiter and Saturn, and the latter happening after a longer interval, ſuch as thoſe of the three ſuperior planets, Mars, Jupiter, and Saturn. But this diviſion has little place in aſtronomy; being founded on the notion of the particular influences, &c. of the heavenly bodies in ſuch and ſuch aſpects.

Aſtrologers maintain, that the deluge was owing to a conjunction of all the planets in Capricorn; and that the conflagration will be occaſioned by their conjunction in Cancer: whence they pretend to foretel the end of the world.

The conjunction is the firſt, or the principal, of all the aſpects; and that whence the other aſpects commence; as oppoſition is the laſt, where they terminate. See Character.

The moon is in conjunction with the ſun every month. Her conjunctions and oppoſitions are called by a general name, *ſyzygies.*

Eclipſes of the ſun never happen, but when there is a conjunction of the ſun and moon in or near the nodes of the ecliptic.

Conjunction, in *Grammar*, a particle which expreſſes a relation or dependance between words and phraſes; thus called, becauſe it ſerves to join or connect the parts or members of a diſcourſe, which is its common uſe, and alſo to connect words; ſo as to ſhew the relations which thoſe words ſo united have to other parts of the ſentence.

Conjunctions, however, often unite ſentences, when they appear to unite only words: *e.g.* "Duty and intereſt forbid vicious indulgences;" which form of expreſſion contains in reality two ſentences. See Murray's Eng. Gram. p. 105. ed. 8.

Mr. Harris defines a conjunction to be a part of ſpeech, void of ſignification itſelf, but ſo formed as to help ſignification, by making two or more ſignificant ſentences to be one ſignificant ſentence; and he diſtributes them into ſuch as connect ſentences and their meaning, and ſuch as conjoin the ſentences whilſt they disjoin the ſenſe. The former are *conjunctive*, and are either copulative or continuative, the former joining all ſentences, however incongruous in ſignification, and the latter joining only thoſe which have a natural connection; and the latter *disjunctive*, ſome of which are ſimple, as, *either* it is day *or* it is night, and adverſative, as, it is not day *but* it is night. Hermes, p. 240, &c. See Adversative and Continuative.

Mr. Horne Tooke, in his "Diverſions of Purley," has made ſome remarks, in his uſual manner, on the definition of a conjunction given by Mr. Harris, charging the author not only with ſelf-contradiction, but with great want of perſpicuity. Accordingly he thus ſtates Mr. Harris's definition: "A ſound ſignificant devoid of ſignification, (referring to Mr. Harris's definition of a word), having at the ſame time a kind of *obſcure* ſignification; and yet having neither ſignification nor no ſignification; but a *middle ſomething* between ſignification and no ſignification, ſharing the attributes both of ſignification and no ſignification; and linking ſignification and no ſignification together." This acute and ingenious writer denies conjunctions to be a ſeparate ſort of words or parts of ſpeech by themſelves. For they have not a ſeparate *manner of ſignification*; although they are not *devoid* of ſignification. And the particular ſignification of each muſt be ſought for from amongſt the other parts of ſpeech, by the help of the particular etymology of each reſpective language. By ſuch means alone can we clear away the obſcurity and errors in which grammarians and philoſophers have been involved by the corruption of ſome common words, and the uſeful abbreviations of conſtruction. (See Abbreviation.) And, at the ſame time, we ſhall get rid of that farrago of uſeleſs diſtinctions into conjunctive, adjunctive, disjunctive, ſubdisjunctive, copulative, negative copulative, continuative, &c. &c. &c., which explain nothing; and (as moſt other technical terms are abuſed) ſerve only to throw a veil over the ignorance of thoſe who employ them. In diſmiſſing conjunctions from the rank which they have long held as diſtinct parts of ſpeech, Mr. Tooke cites ſeveral authorities; and among others, biſhop Wilkins, who, in his "Eſſay towards a real Character and a philoſophical Language," (part iii. c. 4. p. 312.), ſays, "According to the true philoſophy of ſpeech, I cannot conceive this kind of words" (ſpeaking of adverbs and conjunctions) "to be properly a diſtinct part of ſpeech, as they are commonly called. But until they can be diſtributed into their proper places, I have ſo far complied with the grammars of inſtituted languages as to place them here together." Mr. Locke, who was much indebted to Wilkins, expreſſes his diſſatisfaction with all the accounts of language which he had ſeen. Sanctius reſcued *quod* particularly from the number of theſe myſterious conjunctions, though he left *ut* amongſt them: and Servius, Scioppius, G. J. Voſſius, Perizonius, and others, have explained and diſplaced many other ſuppoſed adverbs and conjunctions. "In ſhort," ſays the author whom we are now citing, "there is not ſuch a thing as a conjunction in *any* language, which may not, by a ſkilful herald, be traced home to its own family and origin; without having recourſe to contradiction and myſtery with Mr. Harris; or, with Mr. Locke, cleaving open the head of man, to give it ſuch a birth as Minerva's from the brain of Jupiter."

The author's ſcheme is fully developed in the following table, and the ſeveral conjunctions which it exhibits: and he ſays that

If	Are the Imperatives	Ᵹıꝼ	of their reſpective Verbs.	Ᵹıꝼan	To Give.
An		Ān		Ānan	To Grant.
Unleſs		Onleꞅ		Onleꞅan	To Diſmiſs.
Eke		Eac		Eacan	To Add.
Yet		Ᵹeꞇ		Ᵹeꞇan	To Get.
Still		Sꞇell		Sꞇellan	To Put.
Elſe		Āleꞅ		Āleꞅan	To Diſmiſs.
Tho'		Ðaꝼ		Ðaꝼıan	To Allow.
or		or		or	
Though		Ðaꝼıᵹ		Ðaꝼıᵹan	
Bŭt		Boꞇ		Boꞇan	To Boot.
Būt		Be-uꞇan		Beon-uꞇan	To Be-out.
Without		Yýꞃð-nꞇau		Yýꞃðan-uꞇan	To Be-out.
And		Ān-að		Ānan-að	*Dare congeriem.*

Left is the paſt participle Leꞅeð of Leꞅan, To Diſmiſs.

Since	Sıððan Sẏne Sꞇanð-eꞃ Sıððe or Sın-eꞃ	is the participle of Seon. To See.

That is the article or pronoun Ðaꞇ.

For a farther and ample illuſtration and proof of the etymologies above given, and ſeveral others, we muſt refer to Tooke's ΕΠΕΑ ΠΤΕΡΟΕΝΤΑ, or Diverſions of Purley, part i. p. 136—287, ed. 2.

The conjunction, according to the long eſtabliſhed claſſification, is the ſixth of the eight vulgar parts of ſpeech. See Speech.

Conjunctions render the diſcourſe more ſmooth and fluent; and ſerve very good purpoſes in the argumentative and narrative ſtyle; but they muſt ever be omitted where a perſon ſpeaks with emotion, as only ſerving to weaken and enervate it. Boileau obſerves, that nothing gives more warmth and life to a diſcourſe than to drop the conjunctions or copulatives; a paſſion, adds he, embarraſſed with conjunctions and uſeleſs particles, loſes all the fire and vehemence it would require in its progreſs.

Conjunctions are of various kinds.

Conjunctions *copulative*, or *conjunctive*, are thoſe which expreſs a relation of union or compariſon between things; and ſerve to connect or continue a ſentence, as, *and, only, as much as, in the ſame manner as, neither more nor leſs, inaſmuch as, not only, but alſo.*

Conjunctions *adverſative*, thoſe which expreſs a reſtriction, or contrariety; as, *but, nevertheleſs, although, far from.* See Adversative.

Conjunctions *cauſal*, thoſe which ſhew that the reaſon of ſomething is alleged: as, *for, becauſe, ſeeing, the rather ſince, inaſmuch as.*

Conjunctions *concluſive*, thoſe which denote a conſequence drawn: as, *for which reaſon, but then, of conſequence, ſo that,* &c.

Conjunctions *conditional*, are thoſe which import a condition: as, *if, if not, on condition that, provided that, in caſe of.* See Conditional.

Conjunctions *continuative*, thoſe which expreſs a ſucceſſion, or continuation of the diſcourſe: as, *in effect, even, whatever it be.* See Continuative.

Conjunctions *disjunctive*, thoſe which expreſs a relation of ſeparation or diviſion, or which ſerve not only to connect and continue the ſentence, but alſo to expreſs oppoſition of meaning in different degrees: as, *neither, whether, or, though, yet, but,* &c.

Conjunctions *dubitative*, thoſe which expreſs ſome doubt, or ſuſpenſion of opinion: as, *if, that is to ſay,* &c.

Conjunctions *exceptive*, are, *if it be not, unleſs that,* &c.

CONJUNCTIVA Tunica, in *Anatomy*, is the membrane which connects the front of the eyeball to the poſterior ſurface of the eyelids. See Eye.

CONJURATI Fratres. See Fratres.

CONJURATIO, in *Antiquity*, denotes an oath; and *conjuratus* the ſame with *conjurator, viz.* one who is bound by the ſame oath. *Conjurare* is uſed when ſeveral perſons affirm a thing by oath. Mon. Ang. 7. 1. p. 207.

CONJURATION, in *Law*, ſignifies a plot or confederacy, made by perſons combining together by oath or promiſe, to do ſome public harm. But it was more particularly uſed, formerly, for having a perſonal conference with the devil, or ſome evil ſpirit, to know any ſecret, or to effect any purpoſe. Anno 5 Eliz. c. 16.

It is ſaid in ſome of our law books, that the difference between *conjuration* and *witchcraft* is, that the former endeavours by prayers and invocation of God's powerful name, to compel the devil to ſay or to do what the offender commands him; the latter deals rather by friendly and voluntary conference or agreement with the devil or familiar, to have the offender's deſires ſerved, in lieu of blood, or other gift offered to the devil, eſpecially of the offender's ſoul. And both theſe differ from *inchantment* or *ſorcery*; becauſe thoſe were ſuppoſed to be perſonal conferences with the devil, and theſe are but medicines and ceremonial forms of words (commonly called *charms*) without apparition. Cowel.

Hawkins, in his "Pleas of the Crown," (l. i. c. 3.) ſays, that *conjurors* are thoſe, who, by force of certain magic words, endeavour to raiſe the devil, and oblige him to execute their commands. *Witches* are ſuch who, by way of conference, bargain with an evil ſpirit, to do what they deſire of him: and *ſorcerers* are thoſe who, by the uſe of certain ſuperſtitious words, or by the means of images, &c. are ſaid to produce ſtrange effects, above the ordinary courſe of nature. All theſe were anciently puniſhed in the ſame manner as *heretics*, by the writ "de hæretico comburendo," after a ſentence in the eccleſiaſtical court; and they might be condemned to the pillory, &c. upon an indictment at common law. 3 Inſt. 44. H. P. C. 38. The preſident Monteſquieu alſo (Sp. Laws, b. xii. c. 5.) ranks ſorcery and hereſy together; laying it down, at the ſame time, as an important maxim, that we ought to be very circumſpect in the proſecution of magic and hereſy; becauſe the moſt unexceptionable conduct, the pureſt morals, and the conſtant practice of every duty in life, are not a ſufficient ſecurity againſt the ſuſpicion of crimes like theſe. See Witch-*craft*.

Our fore-fathers were ſtronger believers in the ridiculous ſtories that have been generally told concerning witchcraft and ſorcery than any who live in theſe more enlightened times, when they enacted by ſtat. 33 Hen. VIII. c. 8. all witchcraft and ſorcery to be felony without benefit of clergy; and again by ſtat. 1 Jac. I. c. 12. that all perſons invoking any evil ſpirit, or conſulting, covenanting with, entertaining, employing, feeding, or rewarding any evil ſpirit; or taking up dead bodies from their graves to be uſed in any witchcraft, ſorcery, charm, or inchantment; or killing or otherwiſe hurting any perſon by ſuch infernal acts; ſhould be guilty of felony without benefit of clergy, and ſuffer death. And if any perſon ſhould attempt by ſorcery to diſcover hidden treaſure, or to reſtore ſtolen goods, or to provoke unlawful love, or to hurt any man or beaſt, though the ſame were not effected, he or ſhe ſhould ſuffer impriſonment and pillory for the firſt offence, and death for the ſecond. Theſe acts continued in force till lately, to the terror of all ancient females in the kingdom; and many poor wretches were thus ſacrificed to the prejudice of their neighbours, and their own illuſions: not a few having, by ſome means or other, confeſſed the fact at the gallows. But though ſome of the tales that led to theſe penal ſtatutes ſtill exiſt among the uninformed vulgar, as the triumph of impoſture over credulity, and as bugbears to children, inexcuſably employed for this purpoſe; all executions for this dubious crime are now at an end:—our legiſlature having at length followed the wiſe example of Louis XIV. in France, who thought proper by an edict to reſtrain the tribunals of juſtice from receiving informations of witchcraft. (See Voltaire's Age of Lewis XIV. c. 29. Mod. Un. Hiſt. vol. xxv. p. 215.) Yet Voughlans (De Droit Criminel, 353. 459.) ſtill reckons up ſorcery and witchcraft among the crimes puniſhable in France. With us the above recited ſtatutes againſt conjuration and witchcraft are repealed; and no proſecution ſhall be carried on for the future againſt any perſon for conjuration, witchcraft, ſorcery, or inchantment: but where perſons pretend to exerciſe any kind of witchcraft or conjuration, &c. or undertake to tell fortunes, or, from their ſkill in any occult ſcience, to diſcover where goods ſtolen or loſt may be found; they ſhall upon conviction be impriſoned a year, and ſtand in the pillory once in every quarter, in ſome market-town, and may be ordered to give ſecurity for their good behaviour, by ſtat. 9 Geo. II. c. 5.

CONKAIR, in *Geography*, a town of Hindooſtan, in the province of Berar, ſituated between a high rocky hill and the ſouth bank of the Mahanuddee river, which riſes at a place called Sehowah, about 7 coſs S. of Conkair. The rajah of Conkair has built a fortreſs on the ſummit of the hill, and mounted it with two guns.

CONKERE, a poſt of Chineſe Tartary. N. lat. 44° 50'. E. long. 101° 49'.

CONLIE, a ſmall town of France, in the department of the Sarthe, and chief place of a canton, in the diſtrict of Le Mans, 12 miles N.W. from Le Mans. It has 1405 inhabitants. The canton reckons 16 communes, with 13,055 inhabitants upon a territorial extent of 220 kiliometres.

CONLIE'GE, a ſmall town of France, in the department of Jura, and chief place of a canton in the diſtrict of Lons le Saulnier, with 1201 inhabitants. The canton itſelf reckons 20 communes and 9089 inhabitants upon an extent of 142½ kiliometres.

CONLOBONGI, a town of the iſland of Borneo; 120 miles N. of *Banjer-Maſſing*.

CONN, in *Sea Language*. See Cond.

Conn, *Lough*, in *Geography*, a lake of the county of Mayo, Ireland, which is at the foot of mount Neptune, and extends 9 miles in length, but not more than two in breadth. There is a great number of iſlands in this lake, ſome of which are well planted, and being very fertile in fine graſs, ſerve for paſtures to ſheep and other cattle. That kind of trout called *Gillaroo*, is alſo found here in abundance. Dr. Shaw obſerves of theſe, that they do not appear to be ſpecifically different from the common trout, but by living much on ſhell-fiſh, and ſwallowing ſmall ſtones at the ſame time, their ſtomachs acquire a much greater degree of thickneſs, and a kind of muſcular appearance, ſo as to reſemble a ſort of gizzard. Lough Conn ſtretches from N.W. to S.E. between the Killalla and Caſtlebar.

CONNA, in *Botany*, Rheed. See Cassia *Fiſtula*.

Conna, in *Ancient Geography*, a town of Aſia Minor, in the Greater Phrygia. Ptolemy. The 6th council of Conſtantinople places it in Pamphylia.

CONNAC, denotes in Arabia, Paleſtine, Barbary, &c. the place, whether covered or not, where travellers or caravans halt or break off their journey for a time, in order to reſt and refreſh themſelves and their beaſts of burthen. Similar to this was the "malon," or inn (Gen. xlii. 27. xliii. 21, &c.) where the ſons of Jacob opened their ſacks to give their aſſes provender. The appellation Connac in the Eaſt correſponds with the πανδοχειον and καταλυμα in the Old or New Teſtament, which are rendered inns or hoſpitia. But excepting the caravanſaries which may in ſome meaſure anſwer to the πανδοχεια and καταλυματα, there are, properly ſpeaking, no houſes of entertainment in Barbary; at leaſt, in the ſenſe uſually applied to inns or hoſpitia, *i. e.* where travellers can be provided with lodgings, proviſions, and other neceſſaries for their money.

CONNAMARA, the name of a diſtrict, in the county of Galway, Ireland, noted for the woollen ſtockings knit there, and for the wild ſtate of the country. It is in the barony of Ballinahinch, and an account of it will be found under that name. See Ballinahinch.

CONNARUS, in *Botany*, (Κονναρος, the name of a tree deſcribed by Athenæus), Linn. Gen. 830. Schreb. 1116. Willd. 1268. Juſſ. 369, 452, 453. Claſs and order, *monadelphia decandria*. Nat. Ord. *Dumoſæ*, Linn. *Terebintaceæ*, Juſſ.

Gen. Ch. *Cal.* one-leafed, with five ſegments; or five-leaved. *Cor.* petals five, lanceolate, erect, equal. *Stam.* filaments ten, awl-ſhaped, connected at the baſe, (in pairs, Lam.), alternately larger and ſmaller; anthers roundiſh. *Piſt.* germ ſingle (except in one ſpecies), oblong, villous; ſtyle cylindrical; ſtigma obtuſe. *Peric.* capſules gibbous, one-celled, either two-valved or dehiſcent on one ſide. *Seed* ſingle, large.

Eſſ. Ch. Cal. five-cleft or five-leaved. Cor. five-petalled. Capſ. one-celled. Seed ſingle.

Species, 1. C. *aſiaticus.* Ceylon Sumach. Willd. 2. (C. *monocarpus.* Linn. Mart. 1. Rhus zeylanicus trifoliatus phaſeoli facie, floribus copioſis ſpicatis; Burm. Zeyl. 199. tab. 89. Phaſeolus arboreſcens zeylanicus monocarpus; Rai. Supp. 438.) "Leaves ternate; leaflets roundiſh, egg-ſhaped, one-nerved, veined." A tree. *Leaves* alternate, petioled; leaflets acuminate, quite entire, ſmooth, equal, petioled. *Racemes* erect, terminal. A native of the Eaſt Indies. 2. C. *pentagynus.* Lam. 1. Willd. 3. (Cavan. Diſſ. 7. 376. tab. 223.) "Leaves ternate; leaflets roundiſh, egg-ſhaped, three-nerved; flowers pentagynous." A tree. *Branches* cylindrical, ſmooth, leafy. *Leaves* alternate, acute, entire, ſmooth, ſomewhat coriaceous, finely veined underneath. *Flowers* ſmall, numerous, in axillary and terminal ſpikes, forming a kind of panicle; calyx villous on the outſide; piſtils from three to five, villous, ſhort, appearing united at the baſe; ſtyles ſhorter than the ſtamens; ſtigmas flat or truncated. Deſcribed by La Marck from dried ſpecimens without fruit, communicated by Sonnerat. A native of Madagaſcar and Guinea. 3. C. *africanus.* Mart. 2. Lam. 3. Willd. 1. Vahl. Symb. 3. 86. Cavan. Diſſ. 7. 375. tab. 221. (Omphalobium indicum; Gært. vol. i. 253. tab. 46. fig. 3, and vol. ii. præf. p. 33.) "Leaves ternate; leaflets oblong, veined, acuminate." Willd. "Leaves ternate, leaflets egg-ſhaped, acute at both ends, nerved underneath; flowers panicled, monogynous." Lam. A ſhrub. *Branches* cylindrical, ſmooth. *Leaves* alternate, petioled; leaflets four or five inches long, ſmooth, even-ſurfaced above, nerved and veined underneath. *Flowers* ſmall, numerous; panicle compound, oblong, terminal. *Capſules* oblong, almoſt cylindrical, gibbous on one ſide, pointed at both ends, pedicelled, two-valved. Lam. *Capſule* valveleſs, dehiſcent on the gibbous or outer ſide. *Seed* large, ſomewhat kidney-ſhaped, ſmooth, ſhining, dark cheſnut-coloured, with an oblong pit on each ſide; aril incomplete, fleſhy-glandular, variouſly lobed, ſo as to appear curled, its whole length cloſely adhering to the lower and exterior part of the ſeed. Gært. 4. C. *pinnatus.* Lam. 2. Illuſt. tab. 572. Willd. 5. Cavan. Diſſ. 7. 375. tab. 222. (Perimcurigil; Rheed. Mal. 6. 43. tab. 24.) "Leaves ternate and pinnated; leaflets oblong, veined; petals with two briſtles at the baſe." Willd. A tree. *Root* perennial. *Leaflets* of the ſame conſiſtence, and ſimilarly veined with thoſe of C. pentagynus. *Flowers* white, in terminal and axillary panicles; calyx villous on the outſide; petals lanceolate, with two remarkable briſtles a little above the baſe, one on each ſide, pointing downwards, acute and ſomewhat divaricating; germ ſingle, villous. *Capſules* oblong, gibbous one ſide, ſuddenly narrowed at the baſe, ending rather abruptly in a point, one-celled. *Seed* one. A native of the Eaſt Indies; deſcribed from ſpecimens communicated to La Marck by Sonnerat. 5. C. *Santaloides.* Mart. 3. Willd. 4. Vahl. Symb. 3. 87. (Santaloides; Flor. Zey. 408.) "Leaves pinnated; leaflets egg-ſhaped, acuminate; peduncles axillary, aggregate; flowers in racemes." A tree. *Branches* cylindrical, ſmooth. *Leaves* unequally pinnated, ſcattered, remote, petioled; leaflets ſometimes an inch and half long, quite entire, perfectly ſmooth, ſhining above, reticularly veined underneath, on very ſhort channelled petioles. *Peduncles* from four to ſix together, half the length of the leaf, ſmooth; partial ones ſcattered, with three or four pedicelled flowers towards the top. A native of the Eaſt Indies. 6. C. *mimoſoides.* Mart. 4. Willd. 7. Vahl. Symb. 387. "Leaves pinnated; leaflets about twenty-one, oval-oblong, emarginate; racemes axillary." A tree. *Branches* cylindrical, villous towards the top. *Leaves* growing near the ends of the branches, alternate, approximating, on ſlightly villous petioles; leaflets oppoſite or alternate, on very ſhort petioles, inner ones ſmaller, obtuſe, ſmooth, finely veined on the upper ſurface, paler underneath. *Peduncles* axillary, uſually three together, the length of the leaves, ſlightly hoary; pedicels ſcattered, filiform, the loweſt commonly two-flowered. *Flowers* ſmall, with a minute bracte at the baſe of each pedicel. A native of the iſlands of Nicobar.

Connarus *decumbens;* Willd. Vahl. See Hermannia *triphylla.*

Propagation and Culture. C. aſiaticus is uſually propagated in this country by laying down the young branches, which, if tongued in the manner practiſed for carnations, and duly watered, will put out roots in twelve months. They may then be cut off from the old plants, and planted in ſeparate ſmall pots, which ſhould be filled with light freſh earth and plunged into a moderate hot-bed. They ſhould afterwards be placed in a dry ſtove; but for about three months in ſummer they will bear the open air in a ſheltered ſituation. The cuttings of this plant will ſometimes take root, but without great care ſeldom ſucceed.

CONNATA Folia. See Leaf.

CONNAUGHT, in *Geography*, the name of the weſtern province of Ireland, which contains the counties of Galway, Mayo, Sligo, Leitrim, and Roſcommon. At the time of Strongbow's invaſion, it was a diſtinct kingdom, and its king was monarch of Ireland. This dignity continued until the reign of Henry III.; after which time, the province was divided amongſt petty chieftains, ſome of whom were of Engliſh extraction, until the reign of queen Elizabeth, when the earl of Suſſex, lord deputy, divided it into counties, A. D. 1562; and ſir H. Sidney, lord deputy, eſtabliſhed a lord preſident of Connaught, A. D. 1567. In 1604, ſir Arthur Chicheſter, lord deputy, eſtabliſhed a circuit for judges of aſſize in Connaught. At preſent, the diſtinction of provinces is not attended to in any public acts; and indeed, as calculated to keep up a provincial ſpirit, which has often led to bitter animoſities, it ought to be as much as poſſible diſcountenanced.

Connaught *Worms.* See Worm.

CONNAUX, in *Geography.* a town of France, in the department of the Gard, and diſtrict of Uzés; three leagues N.E. of Uzés.

CONNE, Cone, or Coyne Lough, in the county of Down, Ireland. See Strangford.

CONNEAUT, and alſo Ashtabula, are ſmall rivers of America, in the ſtate of Ohio, which form good harbours for boats and ſmall craft on the borders of lake Erie.

CONNECTICUT, one of the United States of America, called by the ancient nations *Qunnihticut*, lying between 41° and 42° 2′ N. lat., and between 71° 20′ and 73° 15′ W. long.; extending in its greateſt length 100 miles, and greateſt breadth 72 miles; and comprehending about 4674 miles, or about 2,640,000 acres. It is bounded on the north by Maſſachuſetts; on the eaſt by Rhode iſland; on the ſouth by the Sound, which ſeparates it from Long iſland; and on the weſt by the ſtate of New York. Connecticut is divided into eight counties, *viz.* Fairfield, the chief towns of which are Fairfield and Danbury; New Haven, with a capital of the ſame name; Middleſex, the chief towns of which are Middleton and Haddam; and New London, the chief towns of which are New London and Norwich; which four counties extend along the Sound from W. to E.: Litchfield, Hartford, Tolland, and Windham, each having a capital of the ſame name reſpectively, which four counties extend in the ſame direction with the former on the border of the ſtate of Maſſachuſetts. Theſe counties contain about 100 townſhips, which are ſubdivided into pariſhes, each of which has one or more places of public worſhip, ſchool-houſes at convenient diſtances, and a college at New Haven. See College. Each townſhip is a corporation, inveſted with ſufficient powers for its own regulation. The number of repreſentatives is ſometimes 180; but more commonly about 160. The principal rivers in this ſtate are Connecticut, Houſatonick, and the Thames, with their branches; which ſee reſpectively. The whole ſea-coaſt is indented with harbours, which are ſafe and commodious; but the principal are thoſe of New Haven and New London. This ſtate ſends ſeven repreſentatives to Congreſs. The inhabitants are almoſt wholly of Engliſh deſcent, beſides whom they have no Dutch, French, or Germans, and few Scots or Iriſh. The original ſtock, from which have ſprung all the preſent occupiers of Connecticut, and the nnmerous emigrants from hence to every part of the United States, conſiſted of 3000 perſons, who ſettled in the towns of Hartford, New Haven, Windſor, Guilford, Milford, and Weathersfield, about the years 1635 and 1636. In 1756 the population amounted to 130,611 perſons; in 1774 to 197,856; in 1782 to 202,877 whites, and 6273 Indians and negroes; in 1790 to 237,946, of whom 2764 were ſlaves; and by the cenſus in 1800, to 251,002, of whom 121,113 were free white males, 123,528 free white females, 5300 free perſons, except Indians, not taxed, and 951 ſlaves.

Connecticut, notwithſtanding the changes of temperature to which it is ſubject, is very healthful. The ſurface of the country exhibits mountains, hills, and vallies; and though it is very well watered, ſome ſmall parts of it are barren. Its chief productions are Indian corn, rye, wheat, oats, barley, and buck-wheat; flax in abundance, ſome hemp, potatoes of ſeveral kinds, pumpkins, turnips, peas, beans, &c., together with fruits of all kinds which are common to the climate. The ſoil is well adapted for paſturage and mowing, ſo that the farmers are enabled to feed a great number of neat cattle and horſes. This ſtate carries on its chief trade with the Weſt India iſlands, in veſſels from 60 to 140 tons. Its exports conſiſt of horſes, mules, oxen, oak-ſtaves, hoops, pine-boards, oak-planks, beans, Indian corn, fiſh, beef, pork, &c.; and a large number of coaſting veſſels is employed in carrying the produce of Connecticut to the other ſtates; from which they receive in return, rice, indigo, and money. But as New York is nearer, much of its produce, particularly that of the weſtern parts, is carried thither; ſuch as pot and pearl-aſhes, flax-ſeed, beef, pork, cheeſe, and butter, in large quantities. The value of the whole exported produce and commodities from this ſtate, before the year 1774, was then eſtimated at about 200,000*l.* lawful money, annually. In the year ending September 30, 1791, the amount of foreign exports was 710,340 dollars, beſides articles carried to different parts of the United States to a great amount; in 1792 it was 749,925 dollars; in 1793, 770,239 dollars; in 1794, 806,746 dollars; and in 1804, 1,516,110 dollars, comprehending 1,486,882 domeſtic and 29,228 foreign. This ſtate owns and employs in the foreign and coaſting trade more than 32,897 tons of ſhipping. The farmers in Connecticut are generally clothed in plain, decent, homeſpun cloth; and both their linens and woollens are domeſtic manufactures, ſtrong though coarſe; and many of their cloths are fine and handſome. This ſtate has large orchards of mulberry trees, and ſilkworms have been reared with ſuch ſucceſs, that they promiſe a ſupply of ſilk, not only to the inhabitants, but alſo for exportation. New Haven has linen and button manufactories; they have eſtabliſhed a woollen manufactory at Hartford, beſides glaſs works, a ſnuff and powder mill, iron works, and a ſlitting mill. Iron works are alſo eſtabliſhed at Saliſbury and Norwich, and in other parts of the ſtate. Stafford has a furnace, at which are made large quantities of hollow ware, and other ironmongery, ſufficient for the ſupply of the whole ſtate. Paper is manufactured at Norwich, Hartford, New Haven, and in Litchfield county. Ironmongery, hats, candles, leather, ſhoes and boots are manufactured in this ſtate.

Connecticut is laid out in ſmall farms, from 50 to 300 and 400 acres each, which are held by the farmers in fee-ſimple, and are generally well cultivated. The ſtate is chequered with innumerable roads or highways, croſſing each other in every direction; nor can a traveller paſs more than two or three miles, even in the moſt unſettled parts, without finding a houſe or cottage, and a farm in ſuch a condition of improvement as to afford neceſſaries for the ſupport of a family. The whole ſtate, it is ſaid, reſembles a well-cultivated garden, which by induſtry produces the neceſſaries and conveniences of life in great plenty, without its luxuries. To the agricultural mode of life prevailing in this ſtate, which is favourable to temperance and health, and to the eaſe with which a comfortable ſubſiſtence may be obtained, ſo encouraging to early marriage, and alſo to the religious liberty that is maintained, we may aſcribe the rapid advance of this ſtate in population. Luxury has not yet found its way into this ſtate, nor contaminated the manners of the people. The common mode of travelling, both for men and women, is on horſeback; in this ſtate there are few coaches, but many chaiſes and whiſkeys. In the winter is uſed the ſleigh, which is a vehicle drawn by two horſes, and carrying ſix perſons in its box, which hangs on four poſts ſtanding on two ſteel ſliders, or large ſkaites. Dancing, fiſhing, hunting, ſkaiting, and riding in ſleighs on the ice, are the chief amuſements in this ſtate. The men, in general, throughout this province, are tall, ſtout, and robuſt; the women are fair, handſome, and genteel; ſtrictly virtuous, and well-informed. We may obſerve, in general, that there is no part of the world in which the education of all ranks of people is more an object of attention than in this ſtate. Almoſt every town is divided into diſtricts, each of which has a public ſchool kept in it during a great part of the year. Somewhat more than one-third of the money ariſing from a tax on the polls and rateable eſtate of the inhabitants, is appropriated to the ſupport of ſchools in the ſeveral towns, for the education of children and youth. The law enjoins that a grammar-ſchool ſhall be kept in every county-town throughout the ſtate. A certain gravity and ſeriouſneſs of deportment, accompanied with a degree of ſhyneſs and reſerve, appear in the firſt intercourſe of the inhabitants with ſtrangers; but after a ſhort acquaintance, they become very familiar and inquiſitive. Their hoſpitality is exemplary and laudable. In their character there is a certain trait, which renders them leſs amiable; and that is their fondneſs for ſettling even their trivial diſputes "according to law;" and the prevalence of this litigious ſpirit affords employment for a numerous body of lawyers. This party ſpirit is, however, ſubſiding; their public proceedings are conducted with calmneſs and candour; and as they are well informed with regard to their rights, and judicious in the methods they adopt for ſecuring them, the ſtate enjoys a great ſhare of political tranquillity. Another circumſtance, favourable to internal peace and harmony, is the abatement of that rage for theological diſputation which formerly prevailed. The religion, or at leaſt the church government and diſcipline, of this ſtate, is ſuch as ſeems to be peculiarly adapted to a republican government. Each church has a ſeparate juriſdiction, and claims authority to chuſe its own miniſter, to exerciſe judgment, and to enjoy religious inſtitutions, within itſelf. The churches, however, amounting, ſays Morſe, to about 200, of the congregational denomination, in which are about 20,000 communicants and 170 paſtors, are not ſtrictly independant of each other; they aſſociate for mutual convenience and benefit. The aſſociations have power to licence candidates for the miniſtry, to conſult for the general welfare, and to recommend the adoption of meaſures by the churches, but have no authority to enforce them. Of theſe aſſociations there are eleven in the ſtate, and they meet twice in a year. All theſe are combined in one general aſſociation formed in 1709, conſiſting of delegates from the ſeveral aſſociations which meet annually. All forms of religion that are conſiſtent with the peace of ſociety are tolerated in Connecticut; and a ſpirit of liberality and catholiciſm is ſaid to be increaſing. In this ſtate there are few religious ſects; the majority of the people conſiſt of congregationaliſts. Beſides theſe there are epiſcopalians and baptiſts; the epiſcopalian churches are reſpectable, and are under the ſuperintendance of a biſhop.

The conſtitution of Connecticut is founded on its charter, which was granted by Charles II. in 1662, and on a law of the ſtate. Agreeably to this charter, the ſupreme legiſlative authority of the ſtate is veſted in a governor, deputy-governor. 12 aſſiſtants or counſellors, and the repreſentatives of the people, ſtyled the General Aſſembly. The governor, deputy-governor, and aſſiſtants, are annually choſen by the freemen in the month of May. The repreſentatives (whoſe number is not to exceed two from each town) are choſen by the freemen twice a year, to attend the two annual ſeſſions, on the ſecond Tueſday of May and October. The general aſſembly is divided into two branches, called the upper and lower houſes: the former is compoſed of the governor, deputy-governor, and aſſiſtants; and the latter conſiſts of the repreſentatives of the people. No law can paſs without the concurrence of both houſes. They have ſeveral law courts, of which the ſuperior conſiſts of five judges. The general aſſembly only have power to grant pardons and reprieves; to iſſue commiſſions of bankruptcy; or to protect the perſons and eſtates of unfortunate debtors. The feudal ſyſtem of deſcents was never adopted in this ſtate: the whole real eſtate of inteſtates is divided equally among the children, males and females; and all eſtates given in tail muſt be given to ſome perſon then in being, or to their immediate iſſue, and ſhall become fee-ſimple eſtates to the iſſue of the firſt donee in tail. The widow of an inteſtate is entitled to a third part of the perſonal eſtate for ever, and to her dower, or third part of the houſes and lands belonging to the inteſtate at the time of his death, during her life. Attornies are admitted and qualified by the county courts. Before their admiſſion to the bar, they muſt ſtudy two years with a practiſing attorney in the ſtate, if they have had a college education, and three years if they have not: their morals muſt be unblemiſhed, and they muſt be examined by the attornies of the court of the county where they are admitted, and be by them recommended to the court. There are, upon an average, about 15 attornies to each county, and 120 in the whole ſtate.

The American revolution, which ſo eſſentially affected the government of moſt of the colonies, produced no very perceptible alteration in the government of Connecticut. While under the juriſdiction of Great Britain, they elected their own governors, and all ſubordinate civil officers, and made their own laws, in the ſame manner, and with as little controul, as they now do.

The preſent territory of Connecticut, at the time of the firſt arrival of the Engliſh, was poſſeſſed by the Pequot, the Mohegan, Podunk, and many other ſmaller tribes of Indians. The Pequots were numerous and warlike; and their country extended along the ſea-coaſt from Paukatuck to Connecticut river: and about the year 1630, this powerful tribe extended its conqueſts over a conſiderable part of Connecticut, Long Iſland, and a part of Narraganſet, the ancient Indian name of New London; the ſeat of the ſovereign of the whole nation was Pequot. The Mohegans were numerous, and their territory extenſive; it comprehended moſt of New London county, almoſt the whole county of Windham, and a part of the counties of Tolland and Hartford. The Podunks inhabited Eaſt Hartford, and the circumjacent country. In 1774 there remained of the deſcendants of the ancient nations only 1363 perſons; moſt of whom lived at Mohegan, between Norwich and New London. From the rapid decreaſe of the Indians, it is concluded that their number in this ſtate does not now exceed 400.

The firſt grant of Connecticut was made by the Plymouth council to the earl of Warwick in 1630; and, in the following year, he aſſigned this grant to lord Say or Seal, lord Brook, and others. In 1633, an attempt was made on the Engliſh ſettlements by a number of Indian traders, who ſettled at Windſor. In the ſame year, a little before the arrival of the Engliſh, ſome Dutch traders ſettled at Hartford, the remains of whoſe ſettlements are ſtill viſible on the banks of Connecticut river. In 1634, lord Say and Seal, &c. ſent over a ſmall number of perſons, who built a fort at Saybrook, and made a treaty with the Pequot Indians for the lands on Connecticut river. A number of adventurers afterwards ſettled in this province; and in 1644, they purchaſed of the agent of lord Say and Seal, and lord Brook, their right in the colony of Connecticut for 1600*l.* Connecticut and New Haven continued two diſtinct governments for many years; they extended their territories and rapidly increaſed. At length, John Winthrop, eſq., who had been choſen governor of Connecticut, was employed to ſolicit a charter, which was obtained from Charles II. in 1662. Some jealouſy ſubſiſted for a little while between this colony and that of New Haven; but in 1665 theſe two colonies formed an union, which has ever ſince amicably ſubſiſted; and the charter of king Charles continues to be the baſis of their government. At the cloſe of the revolution, Connecticut ceded all her charter claims weſt of Pennſylvania to Congreſs, reſerving only a tract of land as wide as the ſtate of Connecticut, and 120 miles in length; bounded eaſt on the weſtern line of Pennſylvania, and north by lake Erie, containing nearly four millions of acres. The ceſſion was accepted by Congreſs, which eſtabliſhes to Connecticut her title to theſe lands. Morſe's Geog.

CONNECTICUT, the moſt conſiderable river in the eaſtern part of the United States, which riſes in the highlands which ſeparate the ſtates of Vermont and New Hampſhire from Lower Canada. This river has been ſurveyed about 25 miles beyond the 45th degree of latitude to the head ſpring of its northern branch; from which to its mouth it is upwards of 300 miles, purſuing its courſe through a ſettled country, and having on its banks a great number of the moſt flouriſhing and pleaſant towns in the United States.

It is from 80 to 100 rods wide, at the diſtance of 130 miles from its mouth. Its courſe between Vermont and New Hampſhire is generally S.S.W., and alſo through Maſſachuſetts, and part of Connecticut, until it reaches the city of Middleton; after which it runs in a S.S.E. direction to its mouth, fertilizing the lands through which it flows, though its navigation is much obſtructed by a great variety of falls. At its mouth alſo is a bar of ſand, which very much impedes its navigation; however this river is navigable to Hartford city, upwards of 50 miles from its mouth; and the produce of the country for 200 miles above it, is brought thither in boats, which are flat-bottomed, long and narrow, and ſo light as to be portable in carts. Before the conſtruction of locks and canals on this river, they were taken out at three different carrying places, all of which made 15 miles; but theſe obſtructions will, probably, be ſoon wholly removed. Sturgeon, ſalmon, and ſhad, are caught in plenty in their ſeaſon, from the mouth of the river upwards, excepting ſturgeon, which do not aſcend the upper falls; beſides a variety of ſmall fiſh, ſuch as pike, carp, perch, &c.

Connecticut is alſo the name of a ſtream in Long Iſland, in the ſtate of New York, which falls into a bay at the S. ſide of the iſland.

Connecting *Oil.* See Oil.

CONNECTION, or Connexion, a relation whereby one thing adheres to, or depends on another.

Euclid's propoſitions have ſuch a connection among themſelves, that the latter cannot ſubſiſt without the former.

Connection, or *continuity*, in the *Drama*, conſiſts in the joining of the ſeveral ſcenes together.

When the ſcenes of an act ſucceed one another immediately, and are ſo joined as that the ſtage is never left empty, the connection is ſaid to be obſerved.

CONNECTIVES, in *Grammar*, one of the four ſpecies under which, according to Mr. Harris, all words may be included. They are of two kinds, and as they connect ſentences or words, are called by the different names of Conjunctions and Prepositions. Hermes, p. 31, and 237.

CONNELSVILLE, in *Geography*, a town of America, in the county of Waſhington and ſtate of Pennſylvania, pleaſantly ſituated on the Yohiogany, ſettled about ten years, and containing about 80 houſes and 400 inhabitants.

CONNER, Ale. See Ale-*Conner*.

CONNERE', in *Geography*, a town of France, in the department of the Sarthe; 4 leagues E.N.E. of Le Mans.

CONNETABLE *ou Conneſtable de France*, conſtable of France. In the origin of this title, the connetable, who ſucceeded the grand ſénéchal of France, was conſidered as one of the firſt domeſtics of the French kings, in ſhort as maſter of the horſe. Afterwards he became the firſt officer of the crown, chief and conductor of the armies, firſt ſerjeant of the king for executing his orders and commands; for laying hands on the grandees, impriſoning them, and repreſenting them in juſtice. This employment became by degrees ſo eminent, that the marſhals of France were only lieutenants. This office was aboliſhed in the reign of Louis XIII. Anne de Montmorency, who loſt his head on a ſcaffold, was the laſt who filled it.

CONNETABLIE *de France.* This was a particular corps under the orders of the ſeigniors marſhals of France, and conſiſted of 48 guards on horſeback.

CONNIE, in *Geography*, a ſmall river of France, in the department of Eure and Loir, remarkable for being ſo completely dried up in winter, that the fiſh are obliged to hide themſelves in the cavities where there is a little water remaining; in ſummer, on the contrary, its ſtream is always copious.

CONNIVENTES Valvulæ, in *Anatomy*, are folds of the internal, or villous coat, of the ſmall inteſtine. See Intestine.

CONNOIE Bay, in *Geography*, a bay on the S. coaſt of Newfoundland; 50 miles E. of Cape Ray.

CONNOISSEUR, a French term, of late uſed in Engliſh: it literally denotes a perſon well verſed in any thing; being formed of the verb *connoitre, to know, underſtand.* Hence it comes to be uſed in our language for a critic, or perſon who is a thorough judge, or maſter in any way; particularly in matters of painting and ſculpture.

CONNON, in *Geography*, a river of France, called alſo *Aa*, which runs into the Beuvron, ſix miles S.E. of Beuvron.

CONNOR, Bernard, *in Biography*, a native of Dublin, in Ireland, where he was born in 1666, received his education at an academy in France, and at a proper age was ſent to Montpellier, where he was made doctor in medicine in the year 1690. He was ſoon after engaged to ſuperintend the education of two young Poliſh noblemen, with whom, after reſiding ſome time at Paris, he travelled over Italy, and the iſland of Sicily, and then went to Poland, where he was appointed phyſician to the king. This did not, however, detain him long in Poland, as we find him practiſing in London, and made fellow of the College of Phyſicians, and of the Royal Society, in the year 1696. He had publiſhed, the preceding year, "Diſſertationes Medico-Phyſicæ de Antris lethiferis, de Montis Veſuvii incendio, de ſtupendo oſſium coalitu. Oxoni, 8vo." He had ſeen, while in Italy, an eruption of Mount Veſuvius, and had viſited the Grotto del Cano, of both which he gives deſcriptions, and of a ſkeleton, in which the vertebræ, ribs, and oſſa innominata, were all firmly united. "Tentamen Epiſtolare de Secretione Animali," in which he attempts to account for the difference in the colour, taſte, and other ſenſible qualities of the humours, ſecreted from the blood. "Evangelium Medici, ſeu Medicina Myſtica de ſuſpenſis Naturæ legibus, Lond. 1697, 8vo.," and in 1698, in the latter part of which year he died, "A compendious Plan of the Body of Phyſic," apparently a text-book, from which he had given, or had propoſed giving, a courſe of lectures. To this work he added, a ſhort, but entertaining, account of Poland. Haller. Bib. Med. Eloy. Dict. Hiſt.

Connor, in *Geography*, a village in the county of Antrim, Ireland, that gives name to a biſhopric which was united to that of Down in 1454, and which extends over moſt of the county of Antrim. It contains 395,000 Iriſh acres, which are divided into 76 pariſhes; but from unions, there are only 40 benefices and 43 churches. The church of Liſburn was, by letters patent of James I., made the cathedral; that of Connor is in ruins. Connor is 97 Iriſh miles N. from Dublin, and 17 N. from Belfaſt. Beaufort.

Connor, a river of the iſland of Jamaica, which runs into the ſea, between Rocky point, and port Morant.

CONNTHAL. See Caverium.

CONO, in *Commerce*, a Florence wine meaſure of 10 barrels, each barrel being about 12 gallons.

CONOBEA, in *Botany*, Aubl. See Conopea.

CONOCARPODENDRON. See Protea and Pinus.

CONOCARPUS, (from κωνος, a *cone*, and καρπος, *fruit*) Linn. Gen. 236. Schreb. 321. Willd. 366. Lam. Ill. 353. Gært. 1052. Juſſ. 75. Conocarpe. Enc. Claſs and order, *pentandria*

pentandria monogynia, Nat. Ord. *Aggregatæ*, Linn. *Elæagni*. Juſſ.

Gen Ch. *Cal.* one-leafed, ſuperior, very ſmall, five-cleft; ſegments acute, erect. *Cor.* none (or five-petalled?) *Stam.* Filaments five or ten, awl-ſhaped, erect; anthers globular. *Piſt.* Germ inferior, compreſſed, obtuſe; ſtyle ſimple, ſhort; ſtigma obtuſe. *Peric.* none; Linn. Schreb. Samara; Gært. Capſule very ſmall; rounded, compreſſed, convex and gibbous on the outſide, concave within, with a membranous margin on each ſide, not dehiſcent, one-celled. *Seed* ſolitary, inverſely egg-ſhaped. Lam.

Eſſ. Ch. Corolla five-petalled or none. Seeds naked, ſolitary, inferior. Flowers aggregate. Willd.

Flowers aggregate. Calyx ſuperior, five-cleft. Corolla none. Capſules many, one-ſeeded, affixed to a common axis, imbricated into a cone. Lam.

Sp. 1. C. *erecta*. Linn. Sp. Pl. 1. Mart. 1. Lam. 1. Willd. 1. Jacq. Amer. 78. tab. 22. fig. 1. Lam. Ill. tab. 126. fig. 1. Gært. tab. 177. (C. mangharia; Cates. Car. 2. tab. 33. C. foliis oblongis, floribus in caput conicum. Brown. Jam. 159. Alnus; Pluk. Alm. 18. tab. 240. fig. 3. Alni fructu laurifolia arbor; Sloan. Jam. 135. hiſt. 2. tab. 161. fig. 2. Rudbeckia laurifolia maritima; Amm. herb. 581. Innominata; Plum. MSS. Burm. Amer. tab. 144. fig. 2.) "Erect; leaves lanceolate." Linn. "Erect; leaves lanceolate; cones panicled, pedicelled." Lam. A tree, about thirty feet high. Younger branches angular. *Leaves* alternate from two inches and a half, to three inches long, one inch broad, acute, quite entire, ſmooth, greaſy to the touch, on ſhort petioles, which have frequently two lateral glands near the baſe. *Flowers* greeniſh yellow, ſmall, in globular heads, on ſhortiſh pedicels; common peduncles longer, axillary and terminal, branching into racemes which altogether form a kind of panicle. *Capſules* umbilicated, pubeſcent at their ſummit, cloſely imbricated into roundiſh cones, about the ſize of a pea. Jacquin attributes to his plant ten ſtamens, twice as long as the calyx; but other ſpecimens have only five, about the length of the calyx. They are probably different ſpecies. A native of the Weſt Indies, and the tropical coaſts of America; where it is called button wood or button tree, by the Engliſh, and mangle ſaragoza by the Spaniards. It is uſed for fire wood, but is of little value for any other purpoſe. 2. C. *procumbens*. Linn. Sp. Pl. 2. Mart. 2. Lam. 2. Willd. 2. Jacq. Amer. 79. tab. 52. fig. 2. Pict. 42. tab. 260. fig. 22. (Rudbeckia ſupina; Amm. herb. 581.) "Procumbent; leaves inverſely egg-ſhapped." Linn. "Procumbent; leaves inverſely egg ſhaped; cones ſomewhat racemed, ſeſſile." Lam. A much branched ſhrub, almoſt entirely procumbent, following the irregularities of the rocks among which it grows. *Leaves* alternate, an inch or an inch and a half long, entire, ſhining, on ſhort petioles; petioles with an oblong gland on the edge near the baſe, on each ſide. *Flowers* pentandrous and hexandrous, reſembling thoſe of the preceding ſpecies, but ſmaller, and producing cones of a looſer texture. A native of the iſland of Cuba. 3. C. *racemoſa*. Linn. Syſt. Nat. 3. Mart. 3. Willd. 3. Jacq. Amer. 80. tab. 53. Pict. 42. tab. 79. Brown. Jam. 159. n. 1. "Leaves lanceolate; egg-ſhaped, ſomewhat obtuſe; fruit not aggregate." A lofty branching tree, ſometimes dividing into three or four trunks cloſe to the ground. Younger branches oppoſite, red, ſhining. *Leaves* oppoſite, about three inches long, petioled, coriaceous, thickiſh, ſhining, greaſy to the touch, deep green; petiole with two glands at the top. *Flowers* ſmall, ſeſſile, remote, in terminal panicles, compoſed generally of three ſimple, or ſomewhat branched, looſe racemes, many of them abortive; petals five; ſtamens ten, alternately ſhorter. *Fruit* ſeparate; pericarp a coriaceous capſule, containing one or two ſeeds. *Seeds* compoſed of two greeniſh lamellæ, wrapped up into a round body, and involved in a very thin membrane. The lamellæ in the baſe of the pericarp become a round obtuſe ſhining body, forming the axis of the ſeed, deſtined to put forth the roots; for when the capſule falls to the ground, it penetrates the crowned apex, and when the fibres take poſſeſſion of the ſoil, it conſtitutes the rudiment of the future trunk; then the lamellæ increaſing in bulk, burſt the capſule, and become the radical leaves. A native of the Caribbee iſlands, and the neighbouring continent, on ſandy and muddy ſhores; called by the Engliſh white mangrove, and by the Spaniards mangle bobo, or fooliſh mangle.

Obſ. Juſſieu, in his Genera Plantarum, queſtions whether this ſpecies be really a conocarpus. Gærtner obſerves, that Juſſieu's doubt is well founded. La Marck, accordingly, in the Encyclopedie Methodique, excludes it from the genus, promiſing to deſcribe it under manglier, one of the French names for the rhizophora of Linnæus. But Deſrouſſeaux, who, on the ſeceſſion of La Marck, afterwards wrote that article, inſtead of attending to his predeceſſor's reference, and miſled by an ambiguity in the popular uſe of the French word, conſiders it as ſynonymous with conocarpus, and actually gives over again the character of that genus, with the deſcription of La Marck's two acknowledged ſpecies; entirely omitting the conocarpus racemoſa of Linnæus, and not making any farther reference concerning it. This plant ſeems to be ſui generis; for, although the account of the manner in which its ſeed germinates, which we have copied from profeſſor Martyn's Miller, is obſcurely expreſſed; it evidently belongs to Savigny's new natural order paleturier, publiſhed in the Encyclopedie Methodique; but cannot be referred either to bruguiera or to rhizophora, the only two genera of that order, and both included in the rhizophora of Linnæus. See PALETURIER, BRUGUIERA, and RHIZOPHORA. La Marck's eſſential character of conocarpus is drawn up with a view to the excluſion of this ſpecies, and Willdenow's to its admiſſion; the latter, however, has very imperfectly ſucceeded, for his deſcription of C. racemoſa, which ſays expreſsly *flores remoti*, is obviouſly at variance with *flores aggregati* in his eſſential character.

CONOID, CONOIDES, in *Geometry*, a ſolid body, reſembling a cone, except in this, that the ſlant ſides from the baſe to the vertex are not ſtraight lines, as in the cone, but curved.

The conoid is produced by the entire circumvolution of a conic ſection around its axis; and according to the denomination of the ſection from which it is generated, it is differently denominated: if, *v. gr.* the ſolid be produced by the motion of a parabola, it is called a *parabolic conoid*, or *paraboloid;* if by that of an hyperbola, an *hyperbolic conoid*, or *hyperboloid;* and an *elliptic conoid*, or a *ſpheroid*, when produced by the rotation of an ellipſis round one of its axes. See each of theſe articles; and for determining their ſuperficies and ſolidity; ſee SUPERFICIES and SOLIDITY.

If a conchoid, *i.e.* any ſolid formed by the revolution of a conic ſection about its axis, ſuch as a ſpheroid, paraboloid, or hyperboloid, be cut by a plane in any poſition; the ſection will be ſome conic ſection, and all the parallel ſections will be like and ſimilar figures.

Let A B C (*Plate* I. *Conics*, *fig.* 10.) be the generating ſection, or a ſection of the given ſolid through its axis B D, and perpendicular to the propoſed ſection A F C, their common interſection being A C; let G H be any other line meeting the generating ſection in G and H, and interſecting A C in E; and erect E F perpendicular to the plane A B C, and meeting the propoſed plane in F. Then, if A C and G H be conceived to move continually parallel to themſelves, will the rectangle $AE \times EC$ be to the rectangle $GE \times EH$, always in a conſtant ratio; but if G H be perpendicular to B D, the points G, F, H will be in the circumference of a circle whoſe diameter is G H, ſo that $GE \times EH$ will be $= EF^2$; conſequently, $AE \times EC$ will be to EF^2, always in a conſtant ratio; and therefore A F C is a conic ſection, and every ſection parallel to A F C will be of the ſame kind with, and ſimilar to it. Hence,

1. The above conſtant ratio, which $AE \times EC$ has to EF^2, is that of KI^2 to IN^2, the ſquares of the diameters of the generating ſection reſpectively parallel to A C, G H; that is, the ratio of the ſquare of the diameter parallel to the ſection to the ſquare of the revolving axis of the generating plane. This will appear, by conceiving A C and G H to be moved into the poſitions K L, M N, interſecting in I, the centre of the generating ſection.

2. It appears alſo that the axis A C and 2 E F of the ſection, ſuppoſing E now to be the middle of A C, will be to each other, as the diameter K L is to the diameter M N of the generating ſection.

3. If the ſection of the ſolid return into itſelf, it will evidently be an ellipſe. This always happens in the ſpheroid, except when it is perpendicular to the axis; which poſition is alſo to be excepted in the other ſolids, the ſection being then always a circle; in the paraboloid, the ſection is always an ellipſe, excepting when it is parallel to the axis; and in the hyperboloid, the ſection is always an ellipſe, when its axis makes with the axis of the ſolid an angle greater than that which the ſaid axis of the ſolid makes with the aſymptote of the generating hyperbola: the ſection being an hyperbola in all other caſes, except when thoſe angles are equal, and then it is a parabola.

4. If the ſection be parallel to the fixed axis B D, it will be of the ſame kind with, and ſimilar to, the generating plane A B C; that is, the ſection parallel to the axis, in a ſpheroid, is an ellipſe ſimilar to the generating ellipſe; in the paraboloid, the ſection is a parabola ſimilar to the generating parabola; and in an hyperboloid, it is an hyperbola ſimilar to the generating hyperbola of the ſolid.

5. In the ſpheroid, the ſection through the axis is the greateſt of the parallel ſections; in the hyperboloid, it is the leaſt; and in the paraboloid, all the ſections parallel to the axis are equal to one another. For the axis is the greateſt parallel chord line in the ellipſe, but the leaſt in the oppoſite hyperbolas, and all the diameters are equal in a parabola.

6. If the extremities of the diameters, K L, M N, be joined by the line K N, and A O be drawn parallel to K N, and meeting G E H in O, E being the middle of A C, or AE the ſemi-axis, and G H parallel to M N: then will E O be equal to E F, the other ſemi-axis of the ſection. For, by ſimilar triangles, $KI : IN :: AE : EO$. Or, upon G H as a diameter deſcribe a circle meeting E Q, perpendicular to G H, in Q; and E Q is evidently equal to the ſemi-diameter E F.

7. If A P be drawn parallel to the axis B D of the ſolid, and meet the perpendicular G H in P, it will be evident that, in the ſpheroid, the ſemi-axis $EF = EO$ will be greater than E P; but in the hyperboloid, the ſemi-axis $EF = EO$, of the elliptic ſection, will be leſs than E P, and in the paraboloid, $EF = EO$ is always equal to E P.

Scholium. The analogy of the ſections of an hyperboloid to thoſe of the cone, is very remarkable; all the three conic ſections being formed by cutting an hyperboloid in the ſame poſitions as the cone is cut. Thus, let an hyperbola and its aſymptote be revolved together about the tranſverſe axis, the former deſcribing an hyperboloid, and the latter a cone circumſcribing it; then let them be ſuppoſed to be both cut by a plane in any poſition, and the two ſections will be like, ſimilar, and concentric figures: that is, if the plane cut both the ſides of each, the ſections will be concentric, ſimilar ellipſes; if the cutting plane be parallel to the aſymptote, or to the ſide of the cone, the ſections will be parabolas; and in all other poſitions the ſections will be ſimilar and concentric hyperbolas. That the ſections are like figures appears from the foregoing corollaries. That they are concentric will be evident, when we conſider that Cc is $= Aa$, producing A C both ways to meet the aſymptotes in a and c. And that they are ſimilar or have their tranſverſe and conjugate axes proportional to each other, will appear thus:—Produce G H both ways to meet the aſymptotes in g and h; and on the diameters G H, gh, deſcribe the ſemi-circles G Q H, gRh, meeting E Q R, drawn perpendicular to G H, in Q and R; E Q and E R being then evidently the ſemi-conjugate axes, and E C, Ec, the ſemi-tranſverſe axes of the ſections. Now, if G H and A C be conceived to move parallel to themſelves, $AE \times EC$ or CE^2 will be to $GE \times EH$ or EQ^2 in a conſtant ratio, or C E to E Q will be a conſtant ratio; and ſince cE is as Eg, and aE as Eh, $aE \times Ec$ or cE^2 will be to $gE \times Eh$ or ER^2, in a conſtant ratio; but at an infinite diſtance from the vertex, C and c coincide, or $EC = Ec$, as alſo $EG = Eg$; conſequently $EQ = ER$, and then C E to E Q will be $= cE$ to E R; but as theſe ratios are conſtant, if they be equal to each other in one place, they muſt be always ſo; and conſequently $CE : cE :: QE : ER$. This analogy of the ſections will not ſeem ſtrange, when we conſider that a cone is a ſpecies of the hyperboloid; or a triangle a ſpecies of the hyperbola, whoſe axes are infinitely little. See Hutton's Menſuration, part iii. § 4.

The famous ſolid of the leaſt reſiſtance, ſir Iſaac Newton, M. Fatio, and the Marquis De l'Hopital, have demonſtrated to be a conoid.

CONON, in *Biography*, the ſon of Timotheus, and a celebrated general of Athens. He was one of thoſe who ſucceeded Alcibiades, after that celebrated commander had fallen into diſgrace with his countrymen, and diſtinguiſhed himſelf in the Peloponneſian war. See PELOPONNESUS. In an engagement with Callicratidas, the Spartan general, he was defeated; but he afterwards obtained a complete victory, when his antagoniſt loſt his life. About four hundred years before the Chriſtian æra, Conon and Philocles with their fleets were attacked and defeated by Lyſander, the leader of the Spartans. So complete was this victory that Conon barely eſcaped with his life, and ſought refuge in the iſle of Cyprus, while Athens itſelf was reduced to a ſtate of ſervitude, and its conſtitution deſtroyed. In Cyprus, Conon uſed every means in his power to reſcue his country from the ſtate into which ſhe had fallen; he applied to Artaxerxes, the Perſian monarch, for aid againſt the Spartans; obtained his deſires, and was appointed admiral of a large Perſian fleet, which Artaxerxes ſent to ſuccour the Athenians and other Greek ſtates. He had not long been raiſed to this honourable ſituation, when the ſailors mutinied for want of pay: the general haſtened to the court of Perſia, but was not ſuffered to approach the ſovereign, unleſs he ſubmitted to a ſpecies of adoration very unworthy of a noble and dignified mind; this he refuſed, and though denied an audience with his majeſty, his remonſtrances produced the deſired effect, and he was allowed to nominate his own treaſurers to the fleet. Conon reſumed his command, attacked the Spartan admiral Piſander, whom he killed with his own hand; the Spartans were defeated with the loſs of fifty ſhips, and the reſt were glad to ſeek ſhelter in one of their own ports. Conon, having thus obtained the dominion of the ſeas, returned to Attica with plans for reſtoring his country to its former honours. Scarcely had he begun his operations when he was accuſed of a miſapplication of the royal money, and was apprehended for that and other crimes, for which there appears to have been little or no foundation. He did not, however, ſurvive the accuſation; but the manner and particular time of his death are not known, though it was ſuſpected that he was baſely murdered in priſon. Plutarch. Univer. Hiſt.

Conon, a mathematician of conſiderable celebrity at Samos, flouriſhed about three centuries, and died about the year 223, B.C. He was a contemporary and friend of Archimedes, to whom he communicated his writings, and ſent ſome problems, which Archimedes received with approbation, wiſhing them to be publiſhed during the lifetime of their author, in order that from him they might receive a juſt demonſtration. Conon made many obſervations on the eclipſes of the ſun and moon, and gave the name to the conſtellation called Coma-Berenices. His death happened during the period when Archimedes flouriſhed, whoſe eulogium for his friend has come down to the preſent times: ſpeaking of his great genius, he aſks: "How many theorems in geometry, which to others ſeemed impoſſible, would, had Conon lived, have been brought to perfection?" Conon invented a ſpiral, the properties of which having been demonſtrated by Archimedes, it has obtained the name of Archimedes's ſpiral. He is referred to with reſpect in the writings of Propertius and Virgil. Hutton. Moreri. See Conic *Sections*.

Conon, Pope, was by birth a Thracian, and educated in Sicily; from this iſland he went to Rome, where he was ordained preſbyter. Upon the death of pope John V., the diſputes reſpecting a ſucceſſor ran ſo high, that for three months the papacy was vacant: the clergy eſpouſing the intereſts of one candidate, and the army declaring for another. At length Conon was fixed upon, who proved acceptable to all thoſe in whom the appointment was veſted. He aſcended the pontifical throne in the year 686, and died in about a year, but left behind him a character rarely attained by thoſe who have filled that high ſtation. His piety, learning, integrity, and ſuavity of manners, were exemplary, and juſtly celebrated. There was alſo a cardinal of this name, a native of Germany, and advanced to his high rank in the church by pope Paſcal II. He was the avowed and intrepid defender of the high claims of the Roman ſee, and, on this account, ſelected as a proper perſon to preſide at the council of Jeruſalem, in which Henry V., emperor of Germany, was excommunicated, for not ſubmitting to the pope's aſſumed right to the inveſtiture of biſhops and abbots. He was afterwards legate at the council of Soiſſons, in the year 1121, when the treatiſe of the celebrated Adelard, on the Unity of God, was condemned to be burnt. Conon, it is believed, might have been elected to the popedom on the death of Gelaſius, an honour which he declined for motives not now known. His own vote and intereſt he gave to Guy, archbiſhop of Vienne, who was elected pope, and aſſumed the name Callixtus II. Moreri.

CONONIS Aræ, in *Ancient Geography*, a place of Ethiopia, upon the Arabic gulf, according to Strabo; near port Malin.

CONONITES, in *Eccleſiaſtical Hiſtory*, the followers of Conon of Alexandria in the ſixth century, reſembling in their opinions the Severians, Theodosians, and Tritheists.

CONOPA, in *Ancient Geography*, a lake of Greece, in Etolia, afterwards called *Cygnæa*.—Alſo, a town of Greece, in Acarnania, according to Steph. Byz. and Polybius. Strabo ſays, that the town of Arſinoe, which he places in Etolia, had in former times been called *Conopa*.

CONOPEA, in *Botany*, (κωνωπειον, a veil or net to keep off gnats), Mart. (Conobea; Willd. Juſſ. 97. Aubl. Guian. 2. 639. tab. 257.) Claſs and order, *didynamia angioſpermia*. Nat. Ord. *Lyſimachiæ*, Juſſ.

Gen. Ch. *Cal.* perianth one-leafed, five-angled, permanent, five-cleft; ſegments ſomewhat egg-ſhaped, acuminate, erect. *Cor.* one-petalled, ringent; tube oblong, gradually widening; border two-lipped; upper lip erect, emarginate; lower lip trifid, the middle ſegment larger, concave. *Stam.* filaments four, attached, at the bottom, to the tube of the corolla; anthers arrow-ſhaped. *Piſt.* Germ roundiſh; ſtyle filiform, hairy; ſtigma two-lobed. *Peric.* Capſule roundiſh, one-celled, four-valved. *Seeds* numerous, ſmall, fixed to a roundiſh receptacle.

Eſſ. Ch. Calyx five-cleft. Corolla two-lipped. Capſule one-celled, four-valved, with many ſeeds.

Species. C. *aquatica*, a creeping plant, growing naturally near water, ſpreading over its ſurface, and the graſs near the banks, throwing out ſmall fibrous roots from the joints. *Stems* and branches ſquare, each angle bordered by a very ſharp ring. *Leaves* at each joint, oppoſite, embracing the ſtem, kidney-ſhaped, plaited at the nerves, undulated at the edge. *Flowers* blue, axillary, either ſolitary or in pairs; peduncle an inch long, ſlender; calyx with two long, narrow, pointed leaflets at the baſe. *Capſule* with four grooves, partly encloſed by the calyx. A native of Guiana.

CONOPEUM, in *Antiquity*, a ſort of canopy of network, which hung about beds, and was deſigned to keep away gnats or flies; it comes from κωνωψ, *a fly*. A piece of furniture of this kind is now uſed in the Eaſt; and Mr. Harmer (Obſ. on Scripture, vol. iv. p. 405.) ſuggeſts, that if it obtained there at ſo early a period as the time of Saul, it may ſerve to illuſtrate a paſſage of Scripture, *viz.* 1 Sam. xix. 12—17. This writer ſuppoſes that the word tranſlated "a pillow of goats-hair," meant a conopeum or guard againſt gnats. It is in one place tranſlated a "thick cloth," and in another a "ſieve;" and Harmer obſerves, that a cloth of a nature fit to be uſed as a ſieve, is juſt ſuch a thing as a conopeum, or fine net-work or gauze-like cloth. It appeared to be ſomething "relating to the head;" but a conopeum relates to the head as well as a pillow, being a canopy ſuſpended over the whole bed, or at leaſt ſo far as to ſurround the head, and ſuch upper part of the body as might be uncovered. That this kind of defence againſt gnats is now uſed in the Eaſt, Mr. Harmer has ſhewn, from the teſtimony of Maillet (Deſcript. de l'Egypte, lett. ix. p. 37.). The word occurs probably in the ſame ſenſe in 2 Kings. viii. 15.

CONOPEIUM, in *Ancient Geography*, a marſh of Aſia, near the mouth of the river Halys, according to Arrian.—Alſo, a particular part of the Palus Mæotis. Steph. Byz.

CONOPHORUS, in *Botany*, Petiv. Rai. See **Protea** *Nana*.

CONOPOLI, in *Geography*, a town of European Turkey, in the province of Livadia, 10 miles N.E. of Lepanto.

CONOPS, in *Entomology*, a genus of dipterous inſects, the mouth of which is furniſhed with a projecting geniculate proboſcis, and the antennæ clavated and pointed at the end.

The inſects of this genus are remarkably active, and are found in gardens, where they ſubſiſt on the nectareous juices of flowers; their larvæ are unknown. In the true conops, the head is large and nearly hemiſpherical; the eyes large, and almoſt oval, and the antennæ formed of three articulations, the middle one of which is long and cylindrical, the laſt joint terminating in a little point.

The genus conops is divided in the Linnæan ſyſtem into two families; the firſt of which includes thoſe ſpecies which have the ſheath of the ſucker ſingle-valved, abbreviated, and incloſing a ſingle briſtle; the other thoſe with the ſheath conſiſting of two equal valves, and which is geniculated both at the baſe and in the middle. The latter are the myopæ of Fabricius. In the Fabrician Suppl. Ent. Syſt. the Linnæan conops ſubcoleoptratus is deſcribed under the new genus, thereva.

Species.

* *Firſt Section.*

Vesicularis. Blackiſh; hind head veſicular, abdomen yellow with a black baſe. Fabr. Geoffr. Inhabits woods in Europe.

Macrocephala. Black; four of the abdominal ſegments edged with yellow; antennæ and legs rufous. Linn. Like the laſt inhabits Europe, and is found in woods.

Rufipes. Deep-black; abdomen at the baſe ferruginous; ſegments edged with white; legs ferruginous. Fabr.

This ſpecies is a native of Germany. The rib of the wing, and the antennæ are fuſcous, front and poiſers yellow.

Aculeata. Deep-black; inciſures of the abdomen yellow; thorax with two yellow dots on the anterior part. Linn. Fn. Suec. A native of the northern parts of Europe.

Flavipes. Gloſſy-black; abdomen cylindrical; three of the ſegments edged with yellow. Linn. Fn. Suec. This inhabits Europe, and has the legs faſciated with yellow, whence its name.

Picta. Ferruginous; thorax black, varied with yellow, rib of the wing ferruginous. Fabr.

A native of the American iſlands, deſcribed from the cabinet of Smidt.

Vittata. Abdomen cylindrical, hooked, and varied with ferruginous; an abbreviated ſub-marginal black fillet on the wings. Fabr. Inhabits Kiel.

** *Second Section.*

Ferruginea. Ferruginous; abdomen cylindrical and incurved; front yellowiſh. Linn. *Sicus ferrugineus*, Scop. Inhabits woods of Europe.

Petiolata. Antennæ black, the club red; head yellow; abdomen petiolate. Fabr. A native of Siberia.

Atomaria. Grey; abdomen ovate; wings fuſcous, with crowded dots of white. Gmel. An European ſpecies.

Testacea. Ferruginous; thorax black on the back. Fabr. *Stomoxoides*, Schaffer. Found in Germany.

Atra. Abdomen cylindrical and incurved; body black. Fabr. Inhabits woods of Denmark.

Cincta. Teſtaceous; abdomen hooked and faſciated with white. Fabr. A native of the Eaſt Indies. Koenig.

Buccata. Ferruginous; abdomen hooked, grey; face veſicular and white; wings clouded. Linn. Fn. Suec. *Sicus buccatus*, Scopoli. Inhabits woods of Europe.

Annulata. Thorax black; abdomen cylindrical, varied with yellow and black; baſe of the wings ferruginous; legs ferruginous and annulated with brown. Linn. A native of Europe.

Flava. Thorax black; baſe of the abdomen black on the back, with a black mark each ſide, and the two next ſegments with an oblique black ſpot in the middle and at the ſides. Leſk. An European ſpecies.

Cinerea. Cinereous; mouth veſicular and white; tail black. Fabr. Deſcribed from a ſpecimen in the cabinet of Dr. Allioni. It is a native of Italy.

Dorsalis. Ferruginous; thorax fuſcous on the back; abdomen cylindrical and hooked; margin of the ſegments white. Fabr. *Myopa teſtacea*, Mant. Inſ. Inhabits Germany. Smidt.

CONOPONDIABASSIS, in *Ancient Geography*, a name given by Pliny to an iſland at the mouth of the Danube, which the ancients called *Pſeudoſtoma*.

CONORIA, in *Botany*, Juſſ. 287. (Conori; Lam. Encyc. Conohoria; Aubl. Guian. its name in its native country). Claſs and order, *pentandria monogynia*. Nat Ord. *Berberides*, Juſſ.

Gen. Ch. *Cal.* one-leafed, deeply five-cleft; ſegments lanceolate, acute. *Cor.* Petals five, ovate-oblong, erect, doubled, forming a tube, acute, expanding or reflexed at their ſummit, attached to the receptacle of the piſtil; accompanied by five interior, ſmaller, erect, lanceolate, concave, petal-like bodies placed oppoſite to them. (Nectaries?) *Stam.* Filaments five, very ſhort, attached to the baſe of the petal-like bodies; anthers erect, oblong. *Piſt.* Germ ſuperior, roundiſh; ſtyle ſlender, zig-zag; ſtigma capitate. *Peric.* unknown.

Sp. C. *flaveſcens*. Aubl. Guian. tab. 95. A ſhrub, three or four feet high, with numerous, ſcattered, knotty, compound branches near the top. *Leaves* oppoſite, on ſhort petioles, egg-ſhaped, acute, entire, ſmooth, green above, reddiſh underneath, the largeſt of them ſix inches long, and near three inches broad. *Flowers* yellowiſh, alternate, in ſpikes terminating the branches, and ſurrounded with ſcales at the baſe; peduncles with two, ſmall, oppoſite ſcales about the middle. A native of woods in Guiana.

CONOSPERMUM, in *Botany* (κωνος, a *cone*, and σπέρμα, *ſeed*, from the conical or top-ſhaped figure of the ſeed). Smith Tr. of Linn. Soc. v. 4. 213. Claſs and order, *tetrandria monogynia*. Nat. Ord. *Proteæ*; Juſſ. Shuttlecok ſeed.

Gen. Char. *Cal.* none. *Cor.* monopetalous, ringent, four-cleft; tube ſwelling; upper tip vaulted, undivided; lower, in three equal, ſpreading ſegments. *Stam.* four. Anthers ſeſſile, ſingle-celled, two in the hollow of the upper lip; two, which often ſeem abortive, at the baſe of the lower, remote from each other. *Piſt.* Germen ſuperior, inverſely conical, bearded at the ſummit. Style filiform, bent, ſhorter than the corolla. Stigma obtuſe, curved. *Seed* ſolitary, naked, inverſely conical, its upper edge fringed with numerous, ſpreading, ſhining briſtles, about its own length.

Eſſ. Char. Calyx none. Cor. of one petal, ringent, bearing the ſtamens: its upper lip vaulted; under three-cleft. Stigma obtuſe. Seed one, naked, crowned with briſtles.

Obſerv. Conſidering the irregularity of the flower, and the inequality of poſition of the anthers, perhaps this genus might be placed in *didynamia gymnoſpermia*, in which order it would add one to the very few genera that have leſs than four ſeeds; but it has no affinity to any already claſſed there, being nearly allied to that tribe of *proteæ* whoſe flowers are ſimple, not aggregate: and as the anthers are all really ſeſſile, it could not literally accord with the definition of the 14th claſs.

Sp. 1. C. *longifolium.* Smith Exot. Bot. v. 2. 45. t. 82. "Leaves linear, inclining to obovate, entire, ſmooth, with a marginal nerve, and numerous tranſverſe veins." Sm. *Stem* ſhrubby, rigid, branched, about three feet high, with round leafy branches, which are ſilky when young. *Leaves* alternate, ſeveral inches long, entire, ſmooth, varying in breadth from a linear to a narrow obovate figure, tipped with a ſmall point, and tapering at the baſe, into a longiſh ſlender footſtalk. Their margin is marked with a fine nerve, connected by tranſverſe veins with the midrib. *Stipulas* none. *Flower-ſtalks* about the tops of the branches, axillary, much exceeding the leaves in length, each bearing a large bracteated downy corymbus, of white or bluſh-coloured, ſeſſile, cluſtered flowers. *Bracteas* membranous, wedge-ſhaped, pointed, fringed. *Corolla* about a quarter of an inch long, externally downy. *Seed* inverſely conical, or top-ſhaped, brown, downy, crowned with a marginal row of ſpreading reddiſh briſtles, and altogether reſembling a ſhuttlecock. A native of New South Wales, and other parts of New Holland; not yet brought to Europe. The flowers are ornamental, and the aſpect of the whole ſhrub not inelegant. 2. C. *ellipticum.* "Leaves elliptical, rough, edged." Sm. MSS. A more humble and divaricated ſhrub than the former. *Branches* hairy when young, thickly clothed with *leaves*, which are about three quarters of an inch long, crowded, nearly ſeſſile, elliptical, obtuſe, entire, thick, and apparently ſucculent when freſh, concave when dry, ſingle-ribbed, veinleſs, roughiſh underneath, eſpecially at the edges, tipped with a minute point. *Flower-ſtalks* ſituated as in the foregoing, but ſhorter, and more crowded; very downy, as is likewiſe the outſide of the corolla. *Seed* rather ſmaller than the laſt. Sent from New South Wales by John White, M.D. 3. C. *taxifolium.* "Leaves linear-lanceolate, oblique, ſomewhat downy." Sm. MSS. *Branches* long and wand-like, very leafy, ſilky. *Leaves* imbricated, ſcattered, ſeſſile, nearly an inch long, linear-lanceolate, inclining to obovate, oblique, narrow, rigid, pointed, ſingle-ribbed, veinleſs, thick-edged, entire, for the moſt part clothed with ſhort ſilky hairs, rarely ſmooth. *Flowers* ſituated as in the two ſpecies juſt deſcribed, forming a denſe leafy corymbus at the end of each branch, but their ſtalks are leſs compound. In general aſpect and ſtructure they ſeem, as well as the *ſeeds*, to agree preciſely with thoſe of C. *ellipticum.* Gathered alſo at New South Wales by Dr. White. 4. C. *ericifolium.* "Leaves awl-ſhaped, keeled, ſmooth." Sm. MSS. This has very much the habit of the laſt, and their flowers and ſeeds exactly accord. Both ſeem to be rather herbaceous than ſhrubby, though they have the hard rigid texture ſo frequent in New Holland plants. This is the ſmaller of the two. Its *leaves* are ſcarcely more than half an inch long, imbricated, awl-ſhaped, obtuſe, keeled, and ſomewhat triangular, tipped as in the laſt with a ſmall point, roughiſh occaſionally to the touch, but, as far as we can diſcover, always deſtitute of pubeſcence, though the branches are ſilky. Gathered at New South Wales by Dr. White. 5. C. *reticulatum.* "Leaves wedge-ſhaped, jagged, reticulated on both ſides." Sm. MSS. The *ſtems* appear to be herbaceous and procumbent, leafy, hairy, a few inches in length. *Leaves* about three inches long, alternate, erect, wedge-ſhaped, entire at the ſides, dilated and jagged at the extremity, veiny, beautifully reticulated on both ſides, tapering down at the baſe into rigid, furrowed, hairy footſtalks, about their own length, whoſe baſes are dilated, and bordered with a membranous ſheathing ſtipula. *Flower-ſtalks* terminal, two or three together, hairy, erect, ſcarcely ſo tall as the leaves, each bearing a looſe, bracteated, ſimple ſpike of downy, apparently white, flowers, whoſe ſegments are more obtuſe than in the other ſpecies. The moſt remarkable character of C. *reticulatum* conſiſts in the exquiſitely reticulated veins, prominent on both ſides of the leaf, branching off from the main ribs and veins, and forming a fine regular uniform net-work over the whole ſurface, whoſe interſtices are commonly pentagonal, and not more in diameter than grains of common ſand. The veins themſelves are finely hairy. For dried ſpecimens of this moſt beautiful ſpecies we are indebted to Mr. A. Menzies, who diſcovered it at King George's Sound, on the weſt coaſt of New Holland, lat. 35. Its fruit we have not ſeen, but there can be no doubt of its genus.

CONOSTEIN-*Engers*, or *Engers*, in *Geography*, a town of Germany, in the circle of the Lower Rhine; and electorate of Treves; 4 miles N. of Coblentz.

CONOTHATON, in *Ancient Geography*, an epiſcopal ſee of Aſia, under the metropolis of Boſtra.

CONOU, in *Geography*, a town of Perſia, in the province of Lariſtan, on the coaſt of the Perſian gulf; 66 miles E.S.E. of Lar.

CONOVIUM, in *Ancient Geography*, a town of the iſle of Albion, on the route from Segontium or Caernarvon to Deva or Cheſter, according to Antonine's Itinerary. It was diſtant 24 miles from Caernarvon, and is now called Caer-Rhyn.

CONQUASSATION, in *Pharmacy*, a ſpecies of comminution, or a particular operation, by which moiſt concreted ſubſtances, ſuch as recent vegetables, their fruits, lacteſcent ſeeds, and the ſofter parts of animals, are contuſed and agitated in a mortar, until partly by their proper ſucculence, or the affuſion of ſome liquor, they are reduced to a ſoft pulp. Metalline inſtruments are not to be uſed for this purpoſe, becauſe not only the manifeſt, but alſo the latent ſalts of the ſubſtances, ſubjected to this operation, acting on the inſtruments, may derive an adventitious virulent quality from them, which will not only render ſuch ſubſtances unfit for the intended purpoſes, but alſo nauſeous and hurtful when exhibited as medicines. James.

CONQUEROR, in French *Conquerant.* A captain or commander who has ſubdued ſeveral cities or entire countries by force of arms. Alexander the Great, Julius Cæſar, Tamerlane, Mahomet II., &c. were conquerors.

CONQUES, in *Geography*, a ſmall town of France, in the department of Aude, and chief place of a canton in the diſtrict of Carcaſſonne, with a population of 1591 inhabitants. That of the canton amounts to 5635, in 10 communes, upon an extent of one hundred kiliometres.—Alſo, a ſmall town of France, in the department of Aveyron, in the diſtrict of Rhodez, with 806 inhabitants, 15 miles N. from Rhodez. The canton, of which it is the chief place, has 12 communes, with 6597 inhabitants, and meaſures 187 kiliometres and a half.

CONQUEST, in French *Conquete*, the acquiſition of a place, province, or entire country, by a ſuperiority of arms, which compels the conquered to ſubmit to the conqueror.

CONQUEST, in *Civil Juriſprudence*, is the acquiſition of property in common by a number of perſons.

In ſome countries, they confound acquiſition with *conqueſt*; but, according to the moſt general acceptation, acquiſition is the gaining of unappropriated goods before the eſtabliſhment of a community; whereas, by the term *conqueſt*, is ordinarily intended whatever is acquired by a number of perſons in community; or by ſome one for all the others.

As it is more eſpecially in the union of perſons by marriage, that a community of property takes place; it is in reference to them that we frequently uſe the word *conqueſt*. There are, nevertheleſs, conqueſts alſo among other perſons who are in a tacit community or ſociety; ſuch as obtain by particular local cuſtoms.

According to this ſenſe of the word, it has been contended by ſeveral, that William I. claimed this kingdom; that is, not by right of arms, but by right of conqueſt or acqueſt; under promiſe of ſucceſſion made by Edward the Confeſſor, and a contract entered into by Harold, to ſupport his pretenſions to that ſucceſſion; and by old writers, conqueſtus, acquiſitio, and perquiſitio, are frequently uſed as ſynonymous terms.

In conſequence of the prodigious ſlaughter of the Engliſh nobility at the battle of Haſtings, and the fruitleſs inſurrections of thoſe who ſurvived, ſuch numerous forfeitures had accrued, that king William was able to reward his Norman followers with very large and extenſive poſſeſſions; which circumſtance led the monkiſh hiſtorians, and ſuch as have implicitly followed them, to repreſent him as having, by right of the ſword, ſeiſed on all the lands of England, and diſtributed them among his own favourites. This ſuppoſition is grounded upon a miſtaken ſenſe of the word "conqueſt," which, in its feodal acceptation, ſignifies no more than "acquiſition;" and hence many party writers have been led into a ſtrange hiſtorical miſtake, and one, ſays judge Blackſtone, which upon the ſlighteſt examination, will be found to be moſt untrue. See Feodal *Tenure*.

What we call "purchaſe," *perquiſitio*, the feudiſts called "conqueſt," *conqueſtus*, or *conquiſitio*; both denoting any means of acquiring an eſtate out of the common courſe of inheritance. This is ſtill the proper phraſe in the law of Scotland; as it was among the Norman juriſts, who ſtyled the firſt purchaſer (that is, the perſon who brought the eſtate into the family, which at preſent owns it) the conqueror or *conquereur*. This is all that ſeems to have been meant by the appellation that was given to William the Norman, when his manner of aſcending the throne of England was in his own charter, and in thoſe of his ſucceſſors, and alſo by the hiſtorians of the times, entitled *conqueſtus*, and himſelf *conqueſtor* or *conquiſitor*; ſignifying that he was the firſt of his family who acquired the crown of England, and from whom, therefore, all future claims by deſcent muſt be derived; though now, from our diſuſe of the feodal ſenſe of the word, together with the reflection on his forcible method of acquiſition, we are apt to annex the idea of "victory" to this name of "conqueſt," or "conquiſitum," a title which, however juſt with regard to the *crown*, the conqueror never pretended with regard to the *realm* of England; nor, in fact, ever had. See Purchase.

William the Norman, as we have already obſerved, and as ſome have maintained, claimed the crown by virtue of a pretended grant from king Edward the Confeſſor; a grant which, if real, was in itſelf utterly invalid; becauſe it was made, as Harold well obſerved, in his reply to William's demand, *abſque generali ſenatus, et populi conventu et edicto*; and this alſo very plainly implies, that it was then generally underſtood, that the king, with conſent of the general council, might diſpoſe of the crown and change the line of ſucceſſion. William's title, however, was altogether as good as Harold's, who was a mere private ſubject, and an utter ſtranger to the royal blood. The conqueſt, then, by William of Normandy, was, like that of Canute before, a forcible transfer of the crown of England into a new family; but, the crown being ſo transferred, all the inherent properties of the crown were alſo transferred with it. For, the victory obtained at Haſtings not being a victory over the nation collectively, but only over the perſon of Harold, the only right which the conqueror could pretend to acquire thereby, was the right to poſſeſs the crown of England, not to alter the nature of the government. And, therefore, as the Engliſh laws ſtill remained in force, he muſt neceſſarily take the crown ſubject to thoſe laws, and with all its inherent properties; the firſt and principal of which was its deſcendibility. See *Right of* Crown.

Some writers have repreſented William's conqueſt as more extenſive and complete than it has been above ſtated. Scarcely any of thoſe revolutions, it is ſaid, which, both in hiſtory and in common language, have been always denominated conqueſts, appear equally violent, or were attended with ſo ſudden an alteration of power and property. The Roman ſtate, which ſpread its dominion over Europe, left the rights of individuals in a great meaſure untouched; and thoſe civilized conquerors, while they made their own country the ſeat of empire, found that they could derive the greateſt advantage from the ſubjected provinces, by ſecuring to the natives the free enjoyment of their own laws, and of their private poſſeſſions. The barbarians who ſubdued the Roman empire, though they ſettled in the conquered countries, yet being accuſtomed to a rude uncultivated life, found a part only of the land ſufficient to ſupply all their wants; and they were not tempted to ſeize extenſive poſſeſſions, which they knew how neither to cultivate nor to enjoy. But the Normans and other foreigners, who followed the ſtandard of William, were ſo far advanced in the arts as to know the value of a large property; and therefore having made the vanquiſhed kingdom the ſeat of government, and having totally ſubdued the natives, they puſhed the rights of conqueſt, for the gratification both of their avarice and ambition, to the utmoſt extremity. Except the former conqueſt of England by the Saxons themſelves, who were induced, by peculiar circumſtances, to proceed even to the extermination of the natives, it would be difficult to find, in all hiſtory, a revolution more deſtructive, or attended with a more complete ſubjection of the ancient inhabitants. In the conduct of their conquerors, contumely was blended with oppreſſion; and the natives were univerſally reduced to ſuch a ſtate of meanneſs and poverty, that the Engliſh name became a term of reproach, and ſeveral generations elapſed before one family of Saxon pedigree was raiſed to any conſiderable honours, or could ſo much as attain the rank of baron of the realm. "Theſe facts," ſays Mr. Hume (Hiſt. vol. i. p. 283, 8vo.) "are ſo apparent from the whole tenor of the Engliſh hiſtory, that none would have been tempted to deny or elude them, were they not heated by the controverſies of faction; while one party was *abſurdly* afraid of thoſe *abſurd* conſequences, which they ſaw the other party inclined to draw from this event. But it is evident that the preſent rights and privileges of the people, who are a mixture of Engliſh and Normans, can never be affected by a tranſaction which paſſed 700 years ago; and as all ancient authors, who lived neareſt the time, and beſt knew the ſtate of the country, unanimouſly ſpeak of the Norman dominion as a conqueſt by war and arms, no reaſonable man, from the fear of imaginary conſequences, will even be tempted to reject their concurring and united teſtimony."

The Norman invaſion, and conqueſt, as it has been uſually denominated, were important events in the hiſtory of this country; and produced as great an alteration in our laws, as it did in our ancient line of kings:—and though the alteration of the former was effected rather by the conſent of the people, than by any right of conqueſt, yet that conſent ſeems to have been partly extorted by fear, and partly given without any apprehenſion of the conſequences which afterwards enſued. The alterations in our laws which then took place are enumerated by judge Blackſtone; and we ſhall here ſubjoin a ſummary of them. The *firſt* of theſe was the ſeparation of the eccleſiaſtical courts from the civil, which was effected in order to ingratiate the new king with the popiſh clergy, who had been for ſome time endeavouring, in every part of Europe, to exempt themſelves from the ſecular power. This was the more eaſily accompliſhed, becauſe, the diſpoſal of all the epiſcopal ſees being then in the breaſt of the king, he had taken care to fill them with Italian and Norman prelates. The *ſecond* alteration of the Engliſh conſtitution was more violent, and conſiſted in the depopulation of whole countries, for the purpoſes of the king's royal diverſion; and ſubjecting both them, and all the ancient foreſts of the kingdom, to the unreaſonable ſeverities of foreſt laws imported from the continent, by which the ſlaughter of a beaſt was made almoſt as penal as the death of a man. (See Forest and Game.) A *third* alteration in the Engliſh law was effected by narrowing the remedial influence of the county courts, the great ſeats of Saxon juſtice, and extending the *original* juriſdiction of all the king's juſticiars to all kinds of cauſes ariſing in all parts of the kingdom. (See Aula *regia*.) Hence all proceedings in the king's courts were ordained to be carried on in the Norman, inſtead of the Engliſh language; a badge of ſlavery as evident and ſignal as ever was impoſed upon a conquered people, which laſted till king Edward III. obtained a double victory, over the armies of France in their own country, and their language in our courts here at home. A *fourth* innovation was the introduction of the trial by combat, for the deciſion of all civil and criminal queſtions of fact in the laſt reſort. (See Combat.) The *laſt* and moſt important alteration, both in our civil and military polity, was the engrafting on all landed eſtates, a few only excepted, the fiction of feodal tenure; which drew after it a numerous and oppreſſive train of ſervile fruits and appendages; aids, reliefs, primer ſeiſins, wardſhips, marriages, eſcheats, and fines for alienation; the genuine conſequences of the maxim then adopted, that all the lands in England were derived from, and holden, mediately or immediately, of, the crown. See each article reſpectively, and Feodal *Tenure*.

"The nation at this period," ſays judge Blackſtone, "ſeems to have groaned under as abſolute a ſlavery as was in the power of a warlike, an ambitious, and a politic prince to create. The conſciences of men were enſlaved by four eccleſiaſtics, devoted to a foreign power, and unconnected with the civil ſtate under which they lived:—who now imported from Rome for the firſt time the whole *farrago* of ſuperſtitious novelties, which had been engendered by the blindneſs and corruption of the times, between the firſt miſſion of Auguſtin the monk, and the Norman conqueſt; ſuch as tranſubſtantiation, purgatory, communion in one kind, and the worſhip of ſaints and images; not forgetting the univerſal ſupremacy and dogmatical infallibility of the holy ſee. The laws too, as well as the prayers, were adminiſtered in an unknown tongue. The ancient trial by jury gave way to the impious deciſion by battle. The foreſt laws totally reſtrained all rural pleaſures and manly recreations. And in cities and towns the caſe was no better; all company being obliged to diſperſe, and fire and candle to be extinguiſhed by eight at night, at the ſound of the melancholy *curfew*. The ultimate property of all lands, and a conſiderable ſhare of the preſent profits, were veſted in the king, or by him granted to his Norman favourites; who, by a gradual progreſſion of ſlavery, were abſolute vaſſals to the crown, and as abſolute tyrants to the commons. Unheard of forfeitures, talliages, aids, and fines, were arbitrarily exacted from the pillaged landholders, in purſuance of the new ſyſtem of tenure. And to crown all, as a conſequence of the tenure by knight-ſervice, the king had always ready at his command an army of 60,000 knights, or *milites*; who were bound, upon pain of confiſcating their eſtates, to attend him in time of invaſion, or to quell any domeſtic inſurrection. Trade, or foreign merchandize, ſuch as it then was, was carried on by the Jews and Lombards; and the very name of an Engliſh fleet, which king Edgar had rendered ſo formidable, was utterly unknown to Europe; the nation conſiſting wholly of the clergy, who were alſo the lawyers; the barons, or great lords of the land; the knights, or ſoldiery, who were the ſubordinate land-holders; and the burghers, or inferior tradeſmen, who from their inſignificancy happily retained, in their ſocage and burgage tenure, ſome points of their ancient freedom. All the reſt were villeins or bondmen."

"From ſo complete and well-concerted a ſcheme of ſervility, it has been the work of generations for our anceſtors, to redeem themſelves and their poſterity into that ſtate of liberty, which we now enjoy:—and which therefore is not to be looked upon as conſiſting of mere encroachments on the crown, and infringements on the prerogative, as ſome ſlaviſh and narrow-minded writers in the laſt century endeavoured to maintain:—but as, in general, a gradual reſtoration of that ancient conſtitution, whereof our Saxon forefathers had been unjuſtly deprived, partly by the policy, and partly by the force, of the Norman." Blackſt. Com. Book iv. See Constitution.

Conquest, in the *Law of Nations*, is the acquiſition of ſovereignty by force of arms, by ſome foreign prince; who reduces the vanquiſhed under his empire. The right of conqueſt is derived from the laws of war; and when a people is ſubjected, the conduct of the conqueror is regulated by four kinds of law. Firſt, the law of nature, which dictates whatever tends to ſelf-preſervation; ſecondly, our reaſon, which teaches us to uſe others, as we would be treated ourſelves; thirdly, the laws of political ſociety, to which nature has not aſſigned any preciſe boundary; laſtly, the law which is derived from the particular circumſtances attending the conqueſt. Thus, a ſtate conquered by another will be treated in one of the four methods following: Either the conqueror will continue it under its own laws, and will only claim the exerciſe of civil and eccleſiaſtical ſovereignty; or he will impoſe a new form of government; or he will deſtroy the frame of their ſociety, and incorporate the inhabitants with others; or he will exterminate them. Ancient and modern hiſtory will ſupply numerous inſtances of theſe different modes of treatment. See Colony and Plantation.

The right of conqueſt is allowed by the law of nations, if not by that of nature; but in reaſon and civil policy it can mean nothing more than that, in order to terminate hoſtilities, a compact is either expreſsly or tacitly made between the conqueror and the conquered, that if they will acknowledge the victor for their maſter, he will treat them for the future as ſubjects, and not as enemies. *Puffend.* Ls. of Nat. viii. b. 24.

CONQUET, Le, in *Geography*, a pretty, rich, ſmall town of France, in the department of Finiſtere, with a good harbour, and excellent roads; 15 miles weſt from Breſt. It is one of the 84 maritime quarters into which modern France is divided, and the reſidence of a maritime ſyndic who ſuperintends this place, beſides Argenton, Lorſpoder, and Oueſſant.

CONQUISITORES. Among the Romans, theſe were commiſſaries or commiſſioners, charged by their functions with the raiſing of troops in the towns, and throughout the country; and obliged, at the ſame time, to make ſearch for thoſe who wiſhed or attempted to withdraw themſelves from the levy.

CONRAD, or Coenrads, Abraham, in *Biography*, an engraver and deſigner of Holland, who was born about 1620. The works of this artiſt, for the greater part, conſiſt of portraits, many of which are from his own drawings, and prove him to have poſſeſſed very conſiderable talents. His ſtyle of engraving is much varied in his different works: ſome of his prints very much reſemble thoſe of L. Voſtermans. Amongſt his beſt works the following may be enumerated: "Chriſtopher Love," *A. Conrad fec.* in fol.; "Jacob Triglande, Profeſſor of Theology to the Univerſity of Leyden," *Ab. Conradus fecit*, in fol.; "The Flagellation and the Crucifixion of Chriſt," two plates in folio, from Ab. Van Diepenbeck. Huber, Manuel des Arts.

Conrad I., emperor of Germany, was, previouſly to his attaining that high honour, duke of Franconia and Heſſe. On the death of Louis IV. king of Germany, A. D. 912, the nobility of the realm aſſembled at Worms, for the purpoſe of chooſing a ſucceſſor. They offered the crown to Otho, duke of Saxony, by whom, on account of his great age, it was not accepted. He requeſted them to turn their thoughts to the duke of Franconia, who was highly eſteemed for his great talents and excellent character. Upon this recommendation he was called to the vacant throne, though not with that unanimity which is calculated to ſecure general homage. The people of Lorrain were attached to Charles the Simple, whom they wiſhed to proclaim as their ſovereign: Conrad marched thither with great expedition, and by his preſence conciliated thoſe who were diſpoſed to reſiſt his authority. While he was thus engaged, Henry, duke of Saxony, ſon of Otho, joined by the dukes of Suabia and Bavaria, excited a rebellion. This, after ſurmounting ſeveral difficulties, he cruſhed, and gained a complete victory over his enemies. The Hungarians now made a dreadful irruption into his dominions, and, after marking their progreſs with fire and ſword, compelled him to purchaſe a peace on very diſgraceful terms: but, notwithſtanding all the exertions of his enemies, he retained the ſceptre, and conducted the affairs of the empire with conſiderable prudence till the time of his death. His conſtitution being broken by the fatigues to which he had been expoſed, and his health being much injured in conſequence of a wound which he had received in battle, he aſſembled the princes and ſtates of the empire, and ſeriouſly exhorted them to raiſe Henry, duke of Saxony, who had been his enemy, to the imperial throne. This is a rare inſtance, on the records of hiſtory, of a prince ſacrificing his private reſentment to the public good. He ſent the crown, ſceptre, and other regalia to his intended ſucceſſor; and after an active and reſpectable reign of ſeven years, he died, A. D. 918, in peace, with the conſciouſneſs of quitting life under the influence of Chriſtian principles.

Conrad II., emperor of Germany, was likewiſe duke of Franconia; he was ſurnamed The Salic, on account of his having been born on the banks of the river Sala, and was unanimouſly inveſted with ſupreme authority. He ſucceeded Henry II., and was crowned, according to ancient uſage, at Thonza. During the firſt two years of his reign, Conrad was chiefly employed in regulating the police, and other affairs of adminiſtration; but in the third, receiving intelligence that the Lombards had ſhaken off their allegiance, he was obliged to march into Italy. The rebels were ſoon reduced to obedience, and the king proceeded to Rome, where he was ſolemnly crowned by pope John, in preſence of Canute, king of England and Denmark, and Rodolphus, king of Burgundy. He was recalled to Germany, on account of an inſurrection, raiſed by the dukes of Suabia, Carinthia, and Worms, which he readily ſuppreſſed, and brought the offenders to the loweſt ſtate of ſubjection. By a decree of the empire, they were deprived of their dominions. The ſeven ſucceeding years were occupied by wars between the emperor, Poland, Bohemia, and Hungary: the detail of theſe would be unintereſting to our readers. The imperial arms were in general ſucceſsful; and on the demiſe of Rodolphus, Conrad acquired the peaceable poſſeſſion of the ſovereignty of Burgundy. A general revolt againſt the German dominions was planned in Italy, and fomented by many leading perſons: the emperor paſſed ſuddenly into that country, and ſeizing ſome of the principal malcontents, ſent them priſoners to Germany. He beſieged Milan, but without ſucceſs; and ſeverely chaſtiſed Parma. Being urged by the monks of Caſſino to protect them againſt the violence and oppreſſion of Pandulph, prince of Capua, he marched to that place, expelled the prince, and ſeized his country. Returning to Germany, he was ſeized with the gout in his legs, and died ſuddenly at Utrecht, in 1039, in the fifteenth year of his reign. He was univerſally revered as a juſt and magnanimous prince; and all thoſe who diſtinguiſhed themſelves in his ſervice had no reaſon to be diſſatisfied with the remunerations which they obtained. Among many inſtances of his munificence, it is ſaid that one of his attendants, who had loſt his leg in battle, received his boot-full of gold, which the emperor obſerved might defray the expence of his cure. He was interred in the cathedral church of Spires, which he had formerly founded and endowed.

Conrad III., another duke of Franconia and emperor of Germany, was nephew of the emperor Henry V., and elected to the imperial throne at Coblentz in 1138-9, as ſucceſſor to Lothaire II. This meaſure was warmly conteſted by Henry, duke of Bavaria, who poſitively refuſed to ſurrender the regalia, which had been depoſited in his hands by Lotharius. He was, however, at length compelled to ſubmit, with the loſs of his own dominions; and the diſappointment and chagrine which he ſuffered on the occaſion brought him to an early grave. Upon the death of this prince, his brother Guelph, with the aſſiſtance of the king of Sicily, made vigorous exertions for the recovery of the confiſcated duchies: a war enſued, and, after ſeveral indeciſive engagements, the duke was cloſely beſieged by the emperor in the caſtle of Weinſberg, celebrated for the conjugal fidelity and affection of the ladies; who, being permitted to leave the place with whatever they could carry, marched out, each with her huſband on her back. This inſtance of kindneſs and regard ſo much affected the emperor, that he readily came into terms with Guelph and his partizans. In this war we muſt look for the origin of the deſignations of the Guelphs and Ghibellines, which are ſo often referred to on the page of hiſtory. The troubles in Germany were immediately ſucceeded by a revolt of ſeveral of the towns of Italy, which threw off the ſovereignty of the empire, and formed themſelves into independant republics. Conrad was now prevailed on to join a cruſade againſt the Saracens, and took the croſs from the hands of Bernard. He accordingly ſet out for Paleſtine, at the head of ſixty thouſand men. Under his banners a troop of females rode in the attitude and armour of men; and the chief of theſe Amazons, from her gilt ſpurs and buſkins, obtained the epithet of the "golden-footed dame." This expedition proved unfortunate: one half of his troops periſhed by ſickneſs, occaſioned, it is believed, through unwholeſome proviſions, furniſhed by the treachery of the Greek emperor, Manuel Comnenus. Conrad, with the remainder, joined Louis VII. king of France, in the ſiege of Damaſcus, exhibiting great prowefs, but without any ſucceſs. The ſiege was raiſed, and the emperor returned to Germany, where he was overwhelmed with public calamity and private affliction, by another revolt of Guelph, and by the death of his eldeſt ſon. This laſt event preyed on his mind, and evidently affected his health. Aware of his approaching end, he was anxious to provide for the ſucceſſion, and recommended his nephew, Frederic Barbaroſſa, to the ſtates of the empire, as a prince of known courage and tried talents. His recommendation was approved, and Conrad died in a ſhort time after, at Bamberg, in the 14th year of his reign. He left one ſon by his empreſs Gertrude, whoſe tender age precluded him from taking any ſhare in the government.

CONRAD IV., the laſt emperor of Germany of this name, was duke of Suabia, and ſon of the emperor Frederick II. He was declared ſucceſſor to his father in 1250, but pope Innocent IV. refuſed to confirm the election. Conrad, notwithſtanding the denunciations of the pontiff, marched into Italy, in order to take poſſeſſion of the kingdom of the two Sicilies, which had been bequeathed to him by his father. He took the city of Naples after an eight months' ſiege: afterwards Capua and Aquino opened their gates to him. He did not long enjoy his ſucceſs: in 1254, he fell ſick, and died in the flower of youth, leaving one ſon, named Conradin, who, at the early age of fourteen, was beheaded by the orders of Charles of Anjou; and in him ended the line of Suabia. Moreri. Univer. Hiſt. Gibbon's Rom. Empire.

CONRAD is a name diſtinguiſhed in literary hiſtory, as well as among the princes of the earth; but as none of that appellation have become very illuſtrious by their works, we ſhall briefly notice them and their writings in a ſingle paragraph. The firſt was a German abbot of the Benedictine order, about the commencement of the tenth century: he wrote "A Continuation of the Hiſtory of France;" and on that account has, by ſome biographical writers, been ſuppoſed a Frenchman; by others, he has been confounded with Conrad of Cologne, who was author of the life of S. Wolphemius. Towards the concluſion of the eleventh century, *Conrad*, biſhop of Utrecht, flouriſhed, to which office he had been raiſed by his pupil, the emperor Henry. He is chiefly known by a work, entitled, "Apologia de Unitate Eccleſiæ conſervanda, et Schiſmate inter Henricum IV. Imp. ac Greg. VIII. Pont. Max." He wrote alſo a ſpirited defence of the imperial right on the ſubject of inveſtitures. The biſhop was aſſaſſinated in his palace, A. D. 1099, by a Frieſland architect, in revenge for having inſtructed him in the method of erecting maſſy buildings on a ſwampy ſoil, and afterwards employing a rival in conſtructing the collegiate church of which the biſhop was founder.—*Conrad* of Sheurn, a German monk, lived in the thirteenth century, and was author of "A Chronicle," and of more than fifty volumes on different ſubjects, chiefly hiſtorical, of which John of Aventine made much uſe in compoſing part of his annals. By his various writings, this monk obtained the honourable epithet of "philoſopher."—*Conrad* of Lichtenau, abbot of Urſberg, in the thirteenth century, was author of "A chronological Hiſtory," extending from Belus, king of Aſſyria, to the year 1449, which was afterwards continued, by an anonymous writer, to the reign of Charles V. It was originally printed at Straſburg, in 1537, and afterwards, with the continuation, in 1569, at Baſil. It created enemies, by ſome reflections on the wars carried on between the German emperors and the popes. The ſame author is ſaid to have written the lives of the ſaints, in 12 books; but they have not come down to us, and probably were never publiſhed.—*Conrad* of Mentz flouriſhed in the thirteenth century, and is known by a work, entitled, "Chronicum Rerum Moguntiarum," from the year 1140 to 1250, which was firſt publiſhed in 1535, and has undergone ſeveral different impreſſions.—About the ſame period lived *Conrad* of Marpurg, who was the firſt perſon of Germany that received the infamous commiſſion of inquiſitor from the papal ſee; an office which he executed with ſo much cruelty, that at length he fell a ſacrifice to the indignation of popular clamour. He wrote "The Life of the Princeſs Elizabeth of Thuringia," who has obtained a place among the ſaints.—*Conrad* is the name of two Dominican monks, natives of Saxony, in the fourteenth century. One was a member of the chapter of his order in that province, and the other appointed by the pope vicar-general of Saxony, in the year 1350. The former publiſhed, among many other things, "A Commentary on the Book of Job;" "A Concordance to the Bible;" "The Student's Dream;" and "A common-place Book for the Uſe of Preachers."—*Conrad* of Aſti, a Piedmonteſe Dominican monk, was author of "Commentaria in Jus Canonicum," and other pieces. He died in the year 1470.—In the ſixteenth century appeared *Conrad Leontinus*, a learned German Ciſtertian monk, who appears to have been well acquainted with the beſt writers in profane and ſacred literature, and to have maintained an intimate correſpondence with the moſt learned men of his time. He publiſhed, in the year 1507, at Baſil, "Nicholas de Lyra's Commentary on the Bible, with marginal Notes."—There were ſeveral others of this name, but it is needleſs to mention them all. *Conrad* of Mur, canon of the church of Zurich, lived in the thirteenth century, and is known for his treatiſe on the ſacraments, and the lives of the popes: and *Conrad* of Saxony wrote "A Chronicle," and ſome hiſtorical works, to which no date is aſſigned. Moreri.

CONRI, FLORENCE, a Franciſcan friar, was born in the province of Connaught, about the year 1560, and was ſent at an early age into Spain, as a ſtudent in theology and the philoſophy of the times. When he had finiſhed his ſtudies, he travelled into the Low Countries, where he acquired great reputation among the Catholics, by his aſſiduity and zeal in illuſtrating and defending the doctrines of St. Auguſtine. He was author of ſeveral tracts on theological ſubjects, among which were "The Mirror of the Chriſtian Life;" an "Iriſh Catechiſm," printed at Louvain, in 1626; and "Tractatus de Statu parvulorum ſine Baptiſmo decedentium ex hac Vita," Lovanii, 1624. As a politician, he was fixed on to conciliate his countrymen to the meaſures of the court of Spain, when Philip III. attempted the conqueſt of Ireland, during the reign of Elizabeth. On the failure of that enterprize he eſcaped from the country, and ſpent the remainder of his life in the Low Countries, and at Madrid, ſupported by a penſion from Spain, in recompence for the ſervices which he intended, but which proved ineffectual. He died at Madrid, in the year 1629. Moreri.

CONRINGIUS, Herman, a philoſopher of great talents, and almoſt univerſal learning, born at Norden in Eaſt Frieſland in November, 1606, received his education at Helmſtadt, where he was made doctor in medicine in 1636, and ſoon after advanced to the chair of profeſſor in that ſcience. He was alſo, in ſucceſſion, appointed profeſſor in phyſics, law, and politics. For his profound knowledge in the laws of nations and politics, he was conſulted, and made phyſician and aulic counſellor to Chriſtina, queen of Sweden, to the king of Denmark, and to ſeveral of the German princes and electors. Of his capacity for theſe employments abundant proof may be found in his numerous works in philoſophy, medicine, and hiſtory, which were long held in great repute, though now referred to rather from curioſity than for their utility. In all of them, however, there is a wonderful diſplay of learning. In his philoſophy he was a follower of the ſchool of Ariſtotle, as he proclaims in the firſt of his publications, *viz.* "De Calido innato, de Morte, et Vita, et de Origine Formarum, libri, omnia ad Ariſtotelis Sententiam elaborata," Lug. Bat. 1631, 8vo., republiſhed with additions in 1640, 43, and 46; "De Germanicorum Corporum Habitûs antiqui et novi Cauſis, Diſſertatio," Helmſt. 1645, 4to. This has been frequently reprinted. The author has ſome ingenious conjectures on the cauſes of the diminiſhed ſtature, and altered complexion, and habit of body, of the Germans, which he ſhews from indiſputable documents had taken place among theſe people. The ancient Germans were fair, with blue eyes, and abundant yellow hair, "robuſtis nato parentibus, ſero veneri ſe dediſſe, inque conjugio caſtos vixiſſe, et ſuas vires conſervaſſe integriores, et pleniores filiis impretiiſſe, &c. &c. An entire change in their mode of living, the uſe of ſtoves, of tobacco, &c. he conceives to have gradually undermined their conſtitutions, and to have produced the changes he ſtates to have taken place. An edition of this work was printed at Francfort, with notes, by Philip Burgſhaw, 8vo. 1727. "De Hermetica Ægyptiorum vetere, et Paracelſica nova Medicina," Helmſt. 1648, 4to.; reprinted, with additions, 1669: a work abounding with ingenious and learned ſpeculations, but little now attended to. "Introductio in univerſam Artem Medicam, ejuſque ſingulas Partes," 1654; re-edited by Schelhammer, 1687; and again by Hoffman, 1726, 4to.; containing an hiſtory and bib. medica, with obſervations on the principal ſects and writers in medicine, beſides numerous diſſertations on particular diſeaſes, as dropſy, pleuriſy, &c. Conringius is ſaid to have been remarkably diminutive in ſtature, but of great vivacity, and enjoying a ſtrong memory. He retained the ſituation of ſenior of the univerſity of Helmſtadt to the time of his death, which happened on the 12th of December, 1681. His character is contained in the following epitaph:

Hoc tumulo
Clauditur regum principumque conſiliarius,
Juris naturalis gentium publici doctor,
Philoſophiæ omnis peritiſſimus, practicæ et theoreticæ,
Philologus inſignis, orator, poeta, hiſtoricus, medicus,
Theologus,
Multas putas his conditas.
Unus eſt Hermannus Conringius, ſæculi miraculum,
Poſuit Henricus Meibomius.

Haller Bib. Eloy Dict. Hiſt.

CONSABURUS, in *Ancient Geography*, a town of Spain, towards the ſouth-weſt of Althæa Olcadum.

CONSANGUINEO, Writ de, in *Law*. See Assise *de Mort d'Anceſtor*.

CONSANGUINEUS Frater. See Consanguinity.

CONSANGUINITY, the relation of kinſhip, between perſons of the ſame blood, or ſprung from the ſame root; or, as it is defined by writers on theſe ſubjects, "*Vinculum perſonarum ab eadem ſtipite deſcendentium*;" *i. e.* the connection or relation of perſons deſcended from the ſame ſtock or common anceſtor. This conſanguinity is either *lineal*, when it ſubſiſts between perſons, of whom one is deſcended in a direct line from the other; as between A. B. and his father, grandfather, great grandfather, and ſo upwards in the direct aſcending line; or between A. B. and his ſon, grandſon, great grandſon, and ſo downwards in the direct deſcending line. Every generation, in this lineal direct conſanguinity, conſtitutes a different degree, reckoning either upwards or downwards: thus, the father of A. B. is related to him in the firſt degree, and ſo likewiſe is his ſon; his grandſire and grandſon in the ſecond; his great grandſire and great grandſon in the third. This is the only natural way of reckoning the degrees in the direct line, and therefore univerſally obtains, as well in the civil and canon, as in the common, law. Conſanguinity is *collateral*, when relations deſcend from the ſame ſtock or anceſtor, but do not deſcend one from the other. See Collateral.

It is eaſy to compute, by the rules of progreſſion, how many lineal anceſtors any man has within a certain number of degrees. Thus, it would appear that a perſon, at the 20th degree, or the diſtance of 20 generations, hath above a million of anceſtors: and if a ſimilar calculation be made of collateral kindred at the diſtance of 20 degrees forward, on the ſuppoſition that each couple of anceſtors leave, one with another, two children, the number will be 274877906944: as in the following tables:

Table I.

Lineal Degrees.	Number of Anceſtors.
1	2
2	4
3	8
4	16
5	32
6	64
7	128
8	256
9	512
10	1024
11	2048
12	4096
13	8192
14	16384
15	32768
16	65536
17	131072
18	262144
19	524288
20	1048576

In forming this table, it is evident that each perſon has two anceſtors in the firſt degree, and that the number is doubled at every remove, becauſe each of his anceſtors has alſo two immediate anceſtors of his own. In order to find the number of anceſtors at any particular degree, we need only to find a power of 2, the index of which is the number of degrees; *e. g.* $\overline{2}|^{5}$, $\overline{2}|^{10}$, $\overline{2}|^{15}$, &c. will give the correſponding number reſpectively. Or, the number of anceſtors at any even degree may be had by ſquaring the number of anceſtors at half that number of degrees: thus 16, the number of anceſtors at 4 degrees, is the ſquare of 4, the number of anceſtors at two; 256 is the ſquare of 16; 65536 of 256; and the number of anceſtors at 40 degrees would be the ſquare of 1048576, or upwards of a million of millions. Theſe powers are eaſily found by means of logarithms. See PROGRESSION.

TABLE II.

Collateral Degrees.	Number of Kindred.
1	1
2	4
3	16
4	64
5	256
6	1024
7	4096
8	16384
9	65536
10	262144
11	1048576
12	4194304
13	16777216
14	67108864
15	268435456
16	1073741824
17	4294967296
18	17179869184
19	68719476736
20	274877906944

It is obvious that in this table the numbers in the progreſſion increaſe much more rapidly than thoſe of the former table; for though the firſt born is 1, the ratio of the progreſſion is 4; that is, there is one kinſman (a brother) in the firſt degree, who makes, together with A. B., the *propoſitus*, as he is called, the two deſcendants from the firſt couple of anceſtors; and in every other degree, the number of kindred muſt be *quadruple* of thoſe in the degree which immediately precedes it. For, ſince each couple of anceſtors has two deſcendants, who increaſe in a duplicate ratio, it will follow that the ratio in which all the deſcendants increaſe downwards, muſt be double that in which the anceſtors increaſe upwards; but the anceſtors increaſe upwards in a duplicate ratio; therefore the deſcendants muſt increaſe downwards in a double duplicate; that is, in a quadruple ratio. This calculation may be formed by a more compendious proceſs, *viz.* by ſquaring the couples, or half the number of anceſtors at any given degree, which will furniſh the number of kindred we have in the ſame degree, at equal diſtance with ourſelves from the common ſtock, beſides thoſe at unequal diſtances. Thus, in the 10th lineal degree, the number of anceſtors is 1024; its half, or the couples, amount to 512; the number of kindred in the 10th collateral degree amounts, therefore, to 262144, or the ſquare of 512. Or, it will be ſeen in the table that $\overline{4}|^{3} = 64$, the number of kindred in the 4th collateral degree; $\overline{4}|^{4} = 256$, the number in the 5th degree; $\overline{4}|^{6} = 1024$, the number in the 6th degree, &c. and therefore if the number of degrees be denoted by n, $\overline{4}|^{n-1}$, will be the number of kindred in the degree expreſſed by n; which is eaſily obtained by the aid of logarithms in any degree, however remote. If any one will be at the trouble of recollecting the ſtate of the ſeveral families within his own knowledge, and of obſerving how far they agree with this account; that is, whether, on an average, every man has not one brother or ſiſter, four firſt couſins, ſixteen ſecond couſins, and ſo on; he will find that the preſent calculation is very far from being overcharged.

From the records of ſcripture we learn, that there is one couple of anceſtors belonging in common to us all, from whence the whole race of mankind is deſcended; and hence we deduce, as an obvious and undeniable conſequence, that all men are in ſome degree, however remote, related to each other. For, indeed, if we only ſuppoſe each couple of our anceſtors to have left, one with another, two children; and each of thoſe children on an average to have left two more; (and, without ſuch a ſuppoſition, the human ſpecies muſt be daily diminiſhing) we ſhall find that all of us have now ſubſiſting nearly 270 millions of kindred in the 15th degree, at the ſame diſtance from the ſeveral common anceſtors as we ourſelves are; beſides thoſe that are one or two deſcents nearer to or farther from the common ſtock, who may amount to as many more. And, if this calculation ſhould appear incompatible with the number of inhabitants on the earth, it is becauſe, by intermarriages among the ſeveral deſcendants from the ſame anceſtor, a hundred or a thouſand modes of conſanguinity may be conſolidated in one perſon, or he may be related to us a hundred or a thouſand different ways.

The method of computing theſe degrees in the canon law (Decretal. 4. 14. 3 & 9.) which our law has adopted (Co. Litt. 23.) is as follows: We begin at the common anceſtor, and reckon downwards; and in whatſoever degree the two perſons, or the moſt remote of them, is diſtant from the common anceſtor, that is the degree in which they are related to each other. Thus, Titius and his brother are related in the firſt degree; for, from the father to each of them is counted only one; Titius and his nephew are related in the ſecond degree; for the nephew is two degrees removed from the common anceſtor; *viz.* his own grandfather, the father of Titius. See Blackſt. Comm. vol. ii.

Marriage is prohibited by the church to the fourth degree of conſanguinity incluſive; but, by the law of nature, conſanguinity is no obſtacle to marriage, except it be in the direct line. See MARRIAGE.

Conſanguinity terminates in the ſixth and ſeventh degree, excepting in the ſucceſſion to the crown; in which caſe, conſanguinity is continued to infinity.

The civilians call *fratres conſanguinei*, thoſe born of the ſame father; in oppoſition to *fratres uterini*, who are only born of the ſame mother. See DESCENT.

According to the common opinion, thoſe were not allowed to complain of an inofficious teſtament, *i. e.* of being diſinherited without cauſe; excepting from the turpitude of the perſon appointed heir in their place. But Van Water endeavours to ſhew the contrary; and urges, that the *conſanguinei* might plead inofficioſity, even where the teſtament was not made in favour of a perſon incapable. See KINDRED.

CONSAR, in *Geography*, a town of Perſia, in the province of Irak; 52 miles N.W. of Iſpahan.

CONSARBRUCK, or CONZ, a town of Germany, in the electorate of Treves, ſituated at the conflux of the Saar and the Moſelle; 2 miles S. of Treves.

CONSBACH, a town of Sweden, in South Gothland; 32 miles N. of Wardberg.

CONSCIENCE, in *Ethics*, a ſecret teſtimony or judgment of the ſoul, or as ſome have defined it, a diſtinct faculty or power of the mind, by which it gives its approbation

tion to things it does that are naturally good; and reproaches itſelf for thoſe that are evil. Or, conſcience is a dictate of the underſtanding power, concerning moral actions; conſidered as it has the knowledge of laws; and conſequently as conſcious of what is to be done, or not done, with regard to the legiſlator.

In the more popular ſenſe of the word, conſcience is a judgment, either true or falſe, whereby we pronounce a thing good or evil. This makes what we call the inner *forum*, or tribunal. Accordingly, it ſhould be conſidered, not as a mere intellectual light, or informing faculty, a dictate of the practical underſtanding (as the ſchools call it), which directs, admoniſhes, and influences us, in what we *are to do;* but as it *acts* back upon the ſoul by a reflection on what we *have done;* and is, by that means, the ſource and cauſe of all that joy, or dejection of mind, of thoſe internal ſenſations of pleaſure or pain, which attend the practice of great virtues or great vices.

Some divines maintain, that conſcience is infallible; and hold it to be that immutable law whereby God will judge men: they deny that the underſtanding can be the ſource of errors, and lay them all at the door of the will. A man, ſay they, may ſecure himſelf from error, by forbearing to judge of things till he have a clear and diſtinct perception of them.

Some of the ſchoolmen diſtinguiſh between the conſcience antecedent to an action, and that conſequent to it: the firſt, called *antecedent* conſcience, determines what is good, and what evil; and conſequently preſcribes what is to be done, and what avoided. *Conſequent* conſcience is a kind of ſecondary or reflex judgment, with regard to the goodneſs, &c. of things, already done or committed.

The *rule* of conſcience is the will of God, ſo far as it is made known to us, either by the light of nature, or by that of revelation. With reſpect to the knowledge of this rule, conſcience is ſaid to be *rightly informed*, or *miſtaken; firm*, or *wavering*, or *ſcrupulous*, &c. With reſpect to the conformity of our actions to this rule when known, conſcience is ſaid to be *good*, or *evil*, &c.

In a moral view, it is of the greateſt importance that the underſtanding be well informed, in order to render the judgment or verdict of conſcience a ſafe directory of conduct, and a proper ſource of ſatisfaction. Otherwiſe, the judgment of conſcience may be pleaded, and it has actually been pleaded, as an apology for very unwarrantable conduct. Many atrocious acts of perſecution have been perpetrated, and afterwards juſtified, under the ſanction of an erroneous conſcience. It is alſo of no ſmall importance, that the ſenſibility of conſcience be duly maintained and cheriſhed; for want of which men have often been betrayed into criminal conduct without ſelf-reproach, and have deluded themſelves with falſe notions of their character and ſtate.

Dr. Reid (See his "Eſſays on the active Powers of Man," p. 252, &c.) has made the following obſervations on that power of the mind, which we call conſcience. 1. Like all our other powers, it comes to maturity by inſenſible degrees, and may be much aided in its ſtrength and vigour by proper culture. 2. Conſcience is peculiar to man. We ſee no veſtige of it in brute animals; and it is therefore one of thoſe prerogatives by which we are raiſed above them. Conſcience is evidently intended by nature to be the immediate guide and director of our conduct, after we arrive at the years of underſtanding. Other principles may urge and impel; but this only authoriſes. Other principles ought to be controlled by this: this may be, but never ought to be controlled by any other, and never can be with innocence. From theſe obſervations it evidently follows, that the moral faculty of conſcience is both an active and an intellectual power of the mind. As an active principle, it ſometimes concurs with other active principles, ſometimes oppoſes them, and ſometimes is the ſole principle of action. As an intellectual principle, we have by it, and by it alone, the original conceptions of right and wrong in human conduct, in their different degrees and different ſpecies.

Philoſophers in lieu of the word *conſcience*, which ſeems appropriated to theological matters, frequently uſe that of *conſciouſneſs*; which ſee.

The power of conſcience has been remarked in all ages of the world, and under all diſpenſations of religion; and hiſtory, both ſacred and profane, furniſhes innumerable examples, that are eminently inſtructive. One remarkable inſtance of this kind occurs in the hiſtory of Joſeph and his brethren (ſee Gen. chap. xlii. and particularly v. 21.) Another is preſented to us in the account which the evangeliſt Matthew has given us of the feelings and reflections of Herod the tetrarch, when he heard of the fame of Jeſus, after he had occaſioned the death of John the Baptiſt. (See Matth. xiv. 1, 2, 3.) Biſhop Atterbury has admirably pourtrayed the ſtate of Herod's mind, in his excellent ſermon on this ſubject. (Sermons, vol. iv. Serm. 4.) Many inſtances of a ſimilar kind occur in profane hiſtory. We ſhall content ourſelves with ſelecting one, and ſhall give it in the words of the elegant preacher already cited. "Tiberius, that complete pattern of wickedneſs and tyranny, had taken as much pains to conquer theſe fears (referring to the fears of futurity before deſcribed) as any man, and had as many helps and advantages towards it, from great ſplendour and power, and a perpetual ſucceſſion of new buſineſs, and new pleaſures: and yet, as great a maſter of diſſimulation as he was, he could not diſſemble the inward ſenſe of his guilt, nor prevent the open eruptions of it upon very improper occaſions. Witneſs that letter which he wrote to the ſenate from his impure retreat at Capreæ. Tacitus has preſerved the firſt lines of it; and there cannot be a livelier image of a mind filled with diſtraction and deſpair than they afford us: *Quid, ſcribam vobis, P. C. aut quomodo ſcribam, aut quid omnino non ſcribam hoc tempore, Dei me Deæque pejus perdant, quàm perire quotidie ſentio, ſi ſcio!* that is, "What, or how, at this time, I ſhall write to you, fathers of the ſenate, or what indeed I ſhall not write to you, may all the powers of heaven confound me yet worſe than they have already done, if I know or can imagine!" And *his* obſervation upon it is well worthy of *ours*, and very appoſite to our preſent purpoſe: "In this manner (ſays he) was this emperor puniſhed by a reflexion on his own infamous life and guilt; nor was it in vain that the greateſt maſter of wiſdom (he means Plato) affirmed, that were the hearts of tyrants once laid open to our view, we ſhould ſee there nothing but ghaſtly wounds and bruiſes; the conſciouſneſs of their own cruelty, lewdneſs, and ill conduct, leaving as deep and bloody prints on their minds, as the ſtrokes of the ſcourge do on the back of a ſlave. Tiberius (adds he) confeſſed as much, when he uttered theſe words; nor could his high ſtation, or even privacy and retirement itſelf, hinder him from diſcovering to all the world the inward agonies and torments under which he laboured." Thus that excellent hiſtorian. We cannot forbear ſubjoining the following fact, related by Mr. Fordyce in his "Dialogues on Education" (vol. ii. p. 401), as a real occurrence which happened in a neighbouring ſtate not many years ago. A jeweller, a man of good character and conſiderable wealth, having occaſion, in the way of his buſineſs, to travel at ſome diſtance from the place of his abode, took along with him a ſervant, in order to take care of his portmanteau. He had with him ſome of his beſt jewels, and a large ſum of money, to which his ſervant was likewiſe privy. When the maſter had occaſion to diſmount on the road, the ſervant, watching his opportunity, took a piſtol from his maſter's ſaddle and ſhot him dead on the ſpot; he then rifled him of his jewels and money, and hanging a large ſtone to his neck, threw him into the neareſt canal. With this booty he made off to a diſtant part of the country, where he had reaſon to believe that neither he nor his maſter were known. There he began to trade in a low way at firſt, that his obſcurity might ſcreen him from obſervation, and in the courſe of ſeveral years ſeemed to riſe, by the natural progreſs of buſineſs, into wealth and conſideration; ſo that his good fortune appeared at once the effect and reward of induſtry and virtue. Of this he counterfeited the appearance ſo well, that he grew into great credit, married into a good family, and by laying out his hidden ſtores diſcreetly, as he ſaw occaſion, and joining to all an univerſal affability, he was admitted to a ſhare in the government of the town, and roſe from one poſt to another, till at length he was choſen chief magiſtrate. In this office he maintained a fair character, and continued to fill it with no ſmall applauſe, both as a governor and a judge; till one day as he ſat on the bench with ſome of his brethren, a criminal was brought before him who was accuſed of murdering his maſter. The evidence came out full, the jury brought in their verdict that the priſoner was guilty, and the whole aſſembly waited the ſentence of the preſident of the court (an office which that day belonged to him), with great ſuſpence. In the mean while he manifeſted an unuſual diſorder and agitation of mind, and his colour often changed; at length he aroſe from his ſeat, and coming down from the bench, placed himſelf juſt by the unfortunate man at the bar. "You ſee before you (ſaid he, addreſſing himſelf to thoſe who had ſat on the bench with him) a ſtriking inſtance of the juſt retaliation of heaven, which this day, after 30 years' concealment, preſents to you a greater criminal than the man juſt now found guilty." He then proceeded to make an ample confeſſion of his guilt, and of all its aggravations. "Nor can I feel (continued he) any relief from the agonies of an awakened conſcience, but by requiring that juſtice be forthwith done againſt me in the moſt public and ſolemn manner." We may eaſily ſuppoſe the amazement of the whole aſſembly, and eſpecially of his fellow-judges. However, they proceeded, upon this confeſſion, to paſs ſentence upon him, and he died with all the ſymptoms of a penitent mind.

CONSCIENCE, *Court of.* See COURT.

CONSCIOUSNESS, in *Logic* and *Metaphyſics*, is the mind's perception of its own exiſtence, faculties, and operations; and, in this view of it, it is one of the ſources of judgment, and one ſpecies of evidence. Conſciouſneſs, ſays Dr. Reid, (Eſſays on the Intellectual Powers of Man, p. 578,) is an operation of the underſtanding of its own kind, and cannot be logically defined. The objects of it are our preſent pains, our pleaſures, our hopes, our fears, our deſires, our doubts, our thoughts of every kind; in a word, all the paſſions, and all the actions and operations of our own minds, while they are preſent. We may remember them when they are paſt: we are conſcious of them only while they are preſent. It is, therefore, a *firſt* principle that every thing exiſts of which we are conſcious. When a man is conſcious of pain, he is certain of its exiſtence; when he is conſcious that he doubts, or believes, he is certain of the exiſtence of theſe operations. And his conviction of the reality of theſe operations is not the effect of reaſoning: it is immediate and intuitive. The exiſtence, therefore, of the paſſions and operations of our minds, of which we are conſcious, is a firſt principle, which nature requires us to believe upon her authority. Indeed, this is the only principle of common ſenſe, which has never been directly called in queſtion, and which retains its authority with the greateſt ſceptics. Mr. Hume, after annihilating body and mind, time and ſpace, action and cauſation, and even his own mind, acknowledges the reality of the thoughts, ſenſations, and paſſions of which he is conſcious. From this ſource of conſciouſneſs we derive all that we know, and indeed all that we can know, of the ſtructure, and of the powers of our own minds; from which we may conclude, that no branch of knowledge ſtands upon a firmer foundation; for ſurely no kind of evidence can go beyond that of conſciouſneſs. Some have confounded conſciouſneſs and reflection, though they are eſſentially diſtinct. The former is common to men at all times, but is inſufficient to give us clear and diſtinct notions of the operations of which we are conſcious, and of their mutual relations, and minute diſtinctions. The ſecond, or attentive reflection upon theſe operations, making them objects of thought, ſurveying them attentively, and examining them on all ſides, is ſo far from being common to all men, that it pertains to very few.

Another firſt principle, in relation to the ſubject of this article is, that the thoughts of which any one is conſcious are the thoughts of a being which he calls *himſelf*, his *mind*, his *perſon*. "If any man aſks a proof of this," ſays Dr. Reid, "I confeſs I can give none; there is an evidence in the propoſition itſelf, which I am unable to reſiſt. Shall I think, that thought can ſtand by itſelf without a thinking being? or that ideas can feel pleaſure or pain? My nature dictates to me that it is impoſſible. And that nature has dictated the ſame to all men, appears from the ſtructure of all languages; for in all languages men have expreſſed thinking, reaſoning, willing, loving, hating, by perſonal verbs, which from their nature require a perſon who thinks, reaſons, wills, loves, or hates. From which it appears, that men have been taught by nature to believe that thought requires a thinker, and reaſon a reaſoner, and love a lover."

"Here," continues Dr. Reid, "we muſt leave Mr. Hume, who conceives it to be a vulgar error, that beſides the thoughts we are conſcious of, there is a mind which is the ſubject of thoſe thoughts." If the mind be any thing elſe than impreſſions and ideas, it muſt be a word without a meaning. The mind, therefore, according to this philoſopher, is a word which ſignifies a bundle of perceptions; or when he defines it more accurately, "It is that ſucceſſion of related ideas and impreſſions, of which we have an intimate memory and conſciouſneſs." Whence it follows that "I am; ſays our author, "that ſucceſſion of related ideas and impreſſions, of which I have the intimate memory and conſciouſneſs. But who is the I that has this memory and conſciouſneſs of a ſucceſſion of ideas and impreſſions? Why, it is nothing but that ſucceſſion itſelf."

Identity of conſciouſneſs, according to Mr. Locke, conſtitutes identity of perſon. For a farther diſcuſſion of this ſubject, ſee IDENTITY.

CONSCRIPT, CONSCRIPTUS, a popular term in the Roman hiſtory, uſed in ſpeaking of ſenators, who were called *conſcript* fathers, *patres conſcripti;* becauſe their names were written in the regiſter, or catalogue of the ſenate.

Livy, lib. i. cap. 1. tells us, that when Brutus filled up the places of the ſenators cut off by Tarquin, with others choſen out of the equeſtrian order, thoſe new ſenators only had the appellation given them of *patres conſcripti*.

CONSCRIPTS alſo denote men raiſed to recruit the Imperial and French armies. All men capable of bearing arms in Hungary and Bohemia, have been uſually enregiſtered and obliged to march wherever their ſervices were called for. The conſcripts in France, during the laſt and preſent war, have been raiſed on ſimilar principles.

The militia of Great Britain comes likewiſe in ſome meaſure under this denomination or deſcription, with this difference, that the men have been raiſed by ballot, and do not leave their native country, unleſs they voluntarily offer their ſervices for that purpoſe.

CONSECRATION, the act of converting or ſetting apart, any profane, or common thing, to a pious purpoſe; with certain ceremonies, prayers, benedictions, &c. appropriate to it.

Conſecration is the reverſe of ſacrilege and profanation, which conſiſt in perverting a thing ſet apart for a pious purpoſe, to a profane and popular one.

The biſhop conſecrates a church, or a chalice; the pope conſecrates medals, agnus dei's, &c. and grants indulgences to thoſe who bear ſuch about them with devotion. The conſecration, or dedication, of a church is an epiſcopal ceremony, conſiſting in a great number of benedictions, with aſperſions and unctions of chriſm, &c. on the walls, both withinſide and without. The form for conſecrating churches, chapels, and church-yards, or places of burials, in England, may be ſeen in Wilkins's Concilia Magnæ Britanniæ, &c. vol. iv. p. 668. It directs that the biſhop and clergy, of whom there are to be at leaſt two, ſhall enter the church or chapel in their ſeveral habits, and, as they walk up from the weſt to the eaſt end, repeat alternately the 24th Pſalm; the biſhop beginning, "The earth is the Lord's," &c. with the "Gloria patri." When they are come to the Lord's table, the biſhop ſitting in his chair ſhall have the inſtrument of dedication, donation, and endowment of the church or chapel, church-yard, or burial-place, preſented to him by the founder, or ſome proper perſon, which he ſhall cauſe to be read by his regiſter, or other officer; and then the inſtrument ſhall be laid on the table, and he ſhall ſtand on the north ſide of it, and turning to the congregation, deliver an addreſs to them, which is followed by ſuitable prayers. One of the prieſts then reads the ſervice of the day, introducing proper pſalms and leſſons: after which, the biſhop proceeds to the communion ſervice, and inſtead of the collect of the day, uſes one proper to the occaſion. When the Epiſtle and Goſpel are read, they are ſucceeded by the Nicene creed and the ſermon; and then the biſhop is to proceed with the ſervice of the communion. When the ſervice in the church is finiſhed, the biſhop and clergy with the people ſhall go into the churh-yard, and make uſe of a prayer for the occaſion. See *ubi ſupra.*

The cuſtom of conſecrating perſons, temples, altars, veſtments, utenſils, &c. is very ancient; and all the ceremonies thereof are preſcribed under the old law. When thoſe conſecrations relate to men, they are properly called *ordinations*; excepting thoſe performed to biſhops and kings, which ſtill retain the name of *conſecration.* Thoſe which only conſiſt in a ceremony inſtituted by the church, are more properly called *benedictions.* When they regard churches, altars, veſſels, &c. they are properly called *dedications.*

In the trial of archbiſhop Laud, A. D. 1644, it was one of the charges alleged againſt him by the commons, that he had traiterouſly endeavoured and practiſed "to alter and ſubvert God's true religion by law eſtabliſhed in this realm, and wiſhed them to ſet up popiſh ſuperſtition and idolatry, and to reconcile us to the church of Rome." One branch of this charge was his introducing and practiſing certain popiſh innovations, and ſuperſtitious ceremonies, not warranted by law, nor agreeable to the practice of the church of England ſince the reformation. In proof of this charge, the managers, on the part of the commons, inſiſted on his countenancing the ſetting up of images in churches, church-windows, and other places of religious worſhip. See IMAGE.

Another popiſh innovation charged on the archbiſhop was, his ſuperſtitious manner of conſecrating chapels, churches, and church-yards, ſuch as had been practiſed in Creed-church, and in the church of St. Giles's in the Fields. The managers objected further, his conſecrating altars with all their furniture, as pattens, chalices, altar-cloths, &c. even to the knife that was uſed for cutting the ſacramental bread; and his dedicating the churches to certain ſaints, together with his promoting annual revels, or feaſts of dedication, on the Lord's day, in ſeveral parts of the country, by which that holy day was profaned, and the people encouraged in ſuperſtition and ignorance. With reſpect to the conſecration of churches, the archbiſhop replied, that the practice was as ancient as Moſes, who conſecrated the tabernacle, with all its veſſels and ornaments; that the temple was afterwards conſecrated by Solomon; that as ſoon as Chriſtian churches began to be built, in the reign of Conſtantine the Great, they were conſecrated, as Euſebius teſtifies concerning the church of Tyre, (E. H. l. x. c. 3.), and ſo it has continued to the preſent time. Beſides, if churches were not conſecrated, they would not be holy, &c. &c. As to the manner of conſecrating Creed-church, St. Giles's, &c. his grace confeſſed that, when he came to the church-door, that paſſage in the Pſalms was read, "Lift up your heads, O ye gates, even lift them up, ye everlaſting doors, that the king of glory may come in;" that he kneeled and bowed at his entrance into the church, as Moſes and Aaron did at the door of the tabernacle; that he declared the place holy, and made uſe of a prayer like one in the Roman pontifical; that afterwards he pronounced divers curſes on ſuch as ſhould profane it, but denied his throwing duſt into the air, in which he ſaid, the witneſſes had forſworn themſelves; for the Roman pontifical does not preſcribe throwing duſt into the air, but aſhes; and he conceived there was no harm, much leſs treaſon in it. As the conſecrating of churches, and alſo dedicating them to God, has been of ancient uſage, ſo has the conſecration of altars and their furniture; and ſuch conſecrations are neceſſary, for elſe the Lord's table could not be called holy, nor the veſſels belonging to it, as they uſually are; yea, there is an holineſs in the altar, which ſanctifies the gift, which it could not do, unleſs itſelf was holy; if there be no dedication of theſe things to God, no ſeparation of them from common uſe, then there can be no ſuch thing as ſacrilege, or difference between our holy table and a common one. And as to the form of conſecrating theſe things, the archbiſhop alleged, that he had it not from the Roman pontifical, but from biſhop Andrews.

The managers for the commons replied, that if the temple was conſecrated, it was by the king himſelf, and not by the high-prieſt; and if the tabernacle was conſecrated, it was by Moſes, the civil magiſtrate, and not by Aaron the high-prieſt; but we read, they ſaid, of no other conſecrating the tabernacle and its utenſils, but anointing them with oil, for which Moſes had an expreſs command; nor of any other conſecrating the temple, but of Solomon's making an excellent prayer in the outward court, not in the temple itſelf, and of his hallowing the middle court by offerings and peace-offerings; and it is obſervable, that the cloud and glory of the Lord filled the temple, ſo that the prieſts could not ſtand to miniſter before Solomon made his prayer, which ſome call his conſecration. But if it ſhould be allowed that the temple was conſecrated in an extraordinary manner, we have no mention either in Scripture, or in Jewiſh writers, of the conſecration of their ſynagogues, to which our churches properly ſucceed. And, after all, it is no concluſive way of arguing, to derive a Chriſtian inſtitution from the practice of the Jewiſh church, becauſe many of their ordinances were temporary, and aboliſhed by the coming of Chriſt. Moreover, it is ſaid, that from the beginning of Chriſtianity, we have no credible authority for conſecrating churches for 300 years. Euſebius, in his life of Conſtantine the Great, does indeed mention his conſecrating a temple which he built over our Saviour's ſepulchre at Jeruſalem; but how?—with prayers, diſputations, preaching, and expoſition of ſcripture, as he expreſsly defines it (cap. 45.) Here were no proceſſions, no knocking at the doors by the biſhop, crying, "Open ye everlaſting doors;" no caſting duſt or aſhes into the air, and pronouncing the ground holy; no reverencing towards the altars, nor a great many other inventions of later ages. Theſe were not known in the Chriſtian church, till the very darkeſt times of popery; nay, in thoſe very dark times, we are told by Otho, the pope's legate, in his Eccleſiaſtical Conſtitutions, that in the reign of king Henry III., there were not only divers pariſh churches, but ſome cathedrals in England, which had been uſed for many years, and yet never conſecrated by a biſhop. But the archbiſhop's method of conſecrating churches, it is ſaid, evidently appears to be a modern popiſh invention; for it is agreed by Gratian, Platina, the Centuriators, and others, that the popes Hyginus, Gelaſius, Silveſter, Felix and Gregory, were the firſt inventors and promoters of it; and it is no where to be found but in the Roman pontifical, publiſhed by command of pope Clement VIII. (De Eccleſiæ dedicatione, p. 209, 280.) for which reaſon it was exploded and condemned by our firſt reformers, and particularly by biſhop Pilkington, in his comment upon Haggai (ch. i. v. 7, 8.) and archbiſhop Parker, who (in his Antiq. Brit. p. 85, 87.) expreſsly condemns the archbiſhop's method of conſecration, as popiſh and ſuperſtitious. (See ALTAR.)

The archbiſhop, however, ſays, that if churches are not conſecrated, they cannot be holy; whereas many places that were never conſecrated are ſtyled holy, as the moſt holy place, and the holy city Jeruſalem; and our homilies ſay, that the church is called holy, not of itſelf, but becauſe God's people reſorting thither are holy, and exerciſe themſelves in holy things; and it is evident that ſanctification, when applied to places, is nothing elſe but a ſeparation of them from common uſe to a religious and ſacred purpoſe, which may be done without the ſuperſtitious method abovementioned; and though the archbiſhop avers, that he had not his form of conſecration from the Roman pontifical, he acknowledges that he had it from biſhop Andrews, who could have had it no where elſe.

As for the conſecration of altars, pattens, chalices, altar-cloths, and other altar-furniture, its original is no higher than the Roman miſſal and pontifical, in both which there are particular chapters and ſet forms of prayer for this purpoſe: but to imagine that theſe veſſels may not be reputed holy, though ſeparated to an holy uſe, unleſs they are thus conſecrated, is deſtitute of foundation in reaſon or ſcripture, and contrary to the practice of the church of England, and the opinion of our firſt reformers. As to the practice of *dedication*, &c. ſee DEDICATION. Neal's Hiſt. of the Puritans, vol. ii. ch. 5. 4to.

CONSECRATION *of the Pope*, a ceremony which is particularly deſcribed by cardinal Raſponi, in his book concerning the church of the Lateran; and which is alſo related by father Bonanni, in his medallic hiſtory of the popes; and by Lenfant, in his hiſtory of the council of Conſtance. "Before the uſage of the conclave was introduced by Gregory the tenth," ſays cardinal Raſponi, "the cardinals, three days after the obſequies of the former pope, convened in the Lateran church, where, after the invocation of the Holy Spirit, and the celebration of maſs, they proceed to the election of a pope. The election being made, the firſt cardinal deacon inveſted the pope elect in his pontifical habits, and announced the name which he choſe to take;" for it has been the cuſtom now, for ſeveral centuries, that the pope ſhould aſſume a new name on being elected. "Afterwards, two cardinals, the moſt eminent in dignity, one on his right hand, the other on his left, conducted him to the altar, where he proſtrated himſelf in adoration of God, whilſt they ſang the *Te Deum*. After the *Te Deum*, the cardinals ſeated the pope in a marble chair, which was behind the altar, under a ſort of dome, or vault, where the pope, being ſet, admitted the cardinals, the biſhops, and ſome others, to kiſs his feet, and to receive the *kiſs of peace*. Then the pope riſing, the cardinals conducted him through the portico to another chair, bored like what is called in French, *ſelle percée*. This chair was thence very properly named *ſtercoraria*, the ſtercorary. It was formerly placed before the portico of the patriarchal baſilic, and is now to be ſeen in the cloiſter of that baſilic." The uſe of theſe chairs, however, was afterwards aboliſhed by Leo the tenth, probably for this, amongſt other reaſons, becauſe the perforated chair was become connected with the fabulous ſtory of the female pope. That, however, is not a proteſtant fable, as ſome perſons ignorantly pretend, for it was current long before the days of Luther. But the continuance of the uſe of that chair preſerved the memory of the ſtory, and might appear to the credulous an evidence of its truth. Whilſt the pope ſat on the ſtercorary, the choir ſang theſe words of ſcripture: Suſcitat de pulvere egenum, et de ſtercore erigit pauperem, ut ſedeat cum principibus, et ſolium gloriæ teneat. Pſalm, cxiii. 7. The laſt clauſe is not in the pſalm. *He raiſeth the poor out of the duſt, and lifteth the needy off the dunghill, that he may ſet him with the princes of his people, and that he may poſſeſs the throne of glory.* The intention of this ceremony, it was ſaid, was to inſinuate to the pope the need there is of the virtue of humility, which ought to be the firſt ſtep of his greatneſs. After remaining ſome time in this chair, the pope received from the hands of the chamberlain three deniers, which he threw to the people, pronouncing theſe words: *Silver and gold I have none for my pleaſure, but what I have I give you.* Afterwards, the prior of the Lateran baſilic, and one of the cardinals, or one of the canons of that baſilic, took the pope between them, and whilſt they walked in the portico, ſhouts of acclamation were raiſed near the baſilic, and the election was declared, with the name which the pope had taken. In this manner they conducted the pope to the baſilic of St. Sylveſter, where, being placed before this baſilic in a chair of porphyry, the prior of the baſilic put into his hands a *ferula*, in ſign of correction and government, and the keys, to denote the power which God gave to St. Peter, prince of the apoſtles, of opening and ſhutting, of binding and looſing, and which paſſes (according to our hiſtorian) ſucceſſively to all the Roman pontiffs. Thence the pope, carrying the ferula, and the keys, went to place himſelf in another chair, reſembling the former; and after remaining there ſome time, reſtored the ferula and the keys to the prior, who girt him with a girdle of red ſilk, giving him a purſe of the ſame colour and ſtuff, wherein there were twelve precious ſtones, and a ſmall bit of muſk. Onuphrius, in his treatiſe on the baſilic of the Lateran, ſays, that it was the prior of this baſilic who gave theſe things to the pope. His ſitting in the two chairs denoted the primacy which St. Peter conferred on him, and the power of preaching the goſpel conferred by St. Paul. The girdle ſignified continence and chaſtity, the purſe denoted the treaſure, out of which the poor were to be nouriſhed, the twelve precious ſtones repreſented the power of the twelve apoſtles, which reſides totally in the pontiff; in fine, the muſk denoted the fragrancy of good works, according to that ſaying, *We are to God a ſweet ſavour of Chriſt.* In this chair the pope elect admitted the miniſters of the palace to kiſs his feet, and to receive the kiſs of peace. There, too, ſeveral pieces of ſilver were delivered to him by the chamberlain, to the value of ten pence. Theſe he threw to the people at three different times, pronouncing theſe words, *He hath ſcattered; he hath given to the poor; his righteouſneſs remaineth for ever.* All this being done, the pope elect went next Sunday, attended by all the orders of the ſacred palace, and the principal people of the city, to the baſilic of the Vatican, and there, before the confeſſion of St. Peter, he was ſolemnly conſecrated by the biſhop of Oſtia, to whom this office ſpecially belongs. After this function, the archdeacon and the ſecond deacon gave the pall to the pope, the archdeacon pronouncing theſe words, *Receive the pall, which is the plenitude of the pontifical office, to the honour of Almighty God, of the moſt happy virgin his mother, of the bleſſed apoſtles St. Peter and St. Paul, and of the holy Roman church.*"

After this deſcription, cardinal Raſponi adds theſe words: "This is what was done when the pontiff was announced or proclaimed in the church of the Lateran; but when the election was made in the Vatican, the pope, immediately after being conducted to the altar by two cardinals, or after having performed his adoration, and offered a ſecret prayer, kneeling, was placed in a chair behind the altar, where he admitted the cardinal biſhops, and the others, during the ſinging of the *Te Deum*, to kiſs his feet, and to receive the kiſs of peace. The following Sunday they aſſembled in the ſame church, and the pope, crowned according to the cuſtom of his anceſtors, went to the Lateran palace; but before entering it, he ſeated himſelf in the *ſtercorary*, where, ſitting down thrice, according to cuſtom, he was introduced by the cardinals into the baſilic, diſtributing money to the populace. There he aſcended a throne behind the altar, where he admitted the canons of the baſilic to kiſs his feet, and to receive the kiſs of peace: which being done, he went to place himſelf in the chairs that were before the oratory of St. Sylveſter, where all was performed that has been recited above. But if it happened that the pope was created out of Rome, all the clergy, when he made his entry into that city, and before entering the gate of the Lateran, went to meet him without the gate, in pontifical habits, with the ſtandard of the croſs and cenſers; and, entering thus into the Lateran church, they obſerved, though in an order ſomewhat different, all the ceremonies mentioned above. And if the pope, coming to Rome after his conſecration, went to the church of St. Peter, the ſame rites were uſed there as in the Lateran church, except only that he did not receive the canons of St. Peter to kiſs his feet in the portico, and that he did not ſit down on the *ſtercorary*, which is not in that church. For this reaſon, the next day after maſs, he went without the tiara to the Lateran palace, and before entering the baſilic, he placed himſelf on the ſtercorary, with the accuſtomed ceremonies."

CONSECRATION, or, as it is more uſually called, BENEDICTION *of the waters*, denotes a ceremony annually practiſed in the Greek church, on the 6th of January, or, as we denominate it, Twelfth-day. For this ceremony at St. Peterſburg, a ſort of wooden chapel or tabernacle, painted green, and ſtuck round with boughs of firs, is conſtructed on the ice of the Neva, between the Admiralty and the Imperial palace. This little building is covered with a dome, reſting on eight ſmall columns, on which ſtands the figure of John the Baptiſt, with the croſs in his hand, amidſt bulruſhes; the inſide of the edifice being decorated with paintings, repreſenting the baptiſm of Jeſus, his transfiguration, and other tranſactions of his life. From the centre of the dome is ſuſpended, by a chain, a monſtrous large holy-ghoſt of wood, over the aperture in the ice, round which are ſpread rich carpets. This little temple is entirely ſurrounded with paliſadoes, which are alſo ornamented with fir-branches; the ſpace within being likewiſe covered with carpets. A ſort of gallery round the building communicates with a window of the palace, from which the imperial family come forth to attend the ceremony; though for ſeveral years paſt (ſays Mr. Tooke) the empreſs and her grandchildren only ſaw the ſolemnity from the windows of the palace. The ceremony begins immediately when the regiments of guards have taken their ſtation on the river. Then the archbiſhop appears amid the ſound of church-bells and the firing of the cannon of the fortreſs, and proceeds along the carpets, attended by his train of biſhops and other eccleſiaſtics, into this little church, where, ſtanding at the hole in the ice, he dips his crucifix three times in the water, at the ſame time repeating prayers, and concludes with a particular one to the great ſaint Nicholas; which done, the water is accounted bleſſed. The prelate then ſprinkles with it the whole ſurrounding multitude, and the banners of all the regiments which are at that time in Peterſburg. When the conſecration is ended, he retires: and now the people preſs in crowds to the hole in the ice, where they drink it with pious avidity; mothers, notwithſtanding the cold, dip their naked babes in the ſtream, and men and women pour it on their heads; every one holds it a duty to take home a veſſel of the water, in order to purify their houſes, and for the cure of certain diſeaſes, for which it is affirmed to be a powerful ſpecific: during which four popes, one at each corner of the aperture, chant a ſort of litany for the occaſion. Tooke's Life of Cath. II. vol. i. p. 180.

CONSECRATION, in *Eccleſiaſtical Law*, is one of the ways by which a benefice may be vacated; the others being by death, by ceſſion, by reſignation, and by deprivation. Thus, when a clerk is promoted to a biſhopric, all his other preferments are void the inſtant he is conſecrated; but there is a method, by the favour of the crown, of holding ſuch livings *in commendam*; which ſee.

CONSECRATION is particularly uſed for the benediction of the elements in the euchariſt.

The Romaniſts define it, the converſion of the bread and wine into the real body and blood of Jeſus Chriſt: and that this is the ſentiment of their church, is evident from the prieſt's elevating the hoſt immediately after conſecration, for the people to adore it. See ELEVATION, HOST, &c.

There is a great controverſy between the Latin and Greek churches, touching the words of conſecration; the common opinion among the Romaniſts, agreeable to St. Thomas and the ſchoolmen, is, that the conſecration of the bread and wine conſiſts in theſe words, *This is my body; this is my blood.* The Greeks, on the contrary, attribute the change of the elements to a certain prayer, which they call the *invocation of the Holy Ghoſt*, rehearſed after the words, *This is* *my body; this is my blood;* which the Greeks maintain are only neceſſary in the proceſs of the conſecration, as they contain the hiſtory of the inſtitution; not as they contribute any thing to the change.

CONSECRATION *of various animals,* was common among the ancient Greeks and Romans. Suetonius mentions the conſecration of a great number of horſes by Julius Cæſar, when he paſſed the Rubicon; and Euſtathius obſerves, that it was common among the Greeks to conſecrate whole herds of cattle, and ſeveral ſorts of fowls, eſpecially geeſe and peacocks, to their gods; giving ſuch animals their liberty, and forbidding all perſons to touch or moleſt them. Athenæus remarks, that they paid the ſame reſpect to fiſhes, particularly thoſe beſt adapted to the palate; and Pliny takes notice, that the dolphin of Octavius Anicius had this favour conferred upon him. Ælian likewiſe relates, that they ſometimes put necklaces about the necks of their fiſhes, and then turned them looſe to their proper element. The Romans alſo had their magical conſecrations: it being cuſtomary for their emperors to offer ſacrifices, repeat charms, and diſpoſe ſtatues in certain places, imagining that ſuch magical operations would hinder barbarians from entering their dominions. Thus Marcus Antoninus endeavoured to fortify himſelf againſt the invaſion of the Marcomanni; and ſome have thought that the palladium of Troy, and the vocal ſtatue of Memnon, were of this kind. Macrobius has given us a particular deſcription of the conſecration of the Roman pontiffs, to the following purport: they dug a pit in the earth, into which the perſon to be conſecrated was let down, dreſſed in prieſtly veſtments, and the pit was covered with a plank bored almoſt full of holes; a bull, crowned with garlands of flowers, was placed on this plank, and his throat being cut, the blood poured through the plank on the prieſt, who received it on his head and face. On aſcending from the pit, covered with blood, he received the ſalutation of *Pontifex.*

CONSECRATION, among *Medaliſts,* is the ceremony of the *apotheoſis* of an emperor; or his tranſlation into heaven, and reception among the gods. See APOTHEOSIS.

On medals, the *conſecration* is thus repreſented: on one ſide is the emperor's head, crowned with laurel, ſometimes veiled; and the inſcription gives him the title of *divus:* on the reverſe is a temple, a buſtum, an altar, or an eagle taking its flight towards heaven, either from off the altar, or from a cippus: at other times the emperor is ſeen in the air, borne up by the eagle; the inſcription always, CONSECRATIO.

Theſe are the uſual ſymbols: yet on the reverſe of that of Antoninus, is the Antonine column. In the apotheoſis of empreſſes, inſtead of an eagle there is a peacock. As to the honours rendered theſe princes after death, they were explained by the words *conſecratio, pater, divus,* and *deus.* Sometimes around the temple or altar are put, *memoria felix,* or *memoriæ æternæ:* for princeſſes, *æternitas,* and *ſideribus recepta:* on the ſide of the head, *dea,* or Θεα. See MEDAL.

CONSECTARY, a propoſition that follows, or is deduced, from ſome preceding definition, lemmata, axioms, concluſions, or the like. Some rather chooſe to call it a *conſequence:* and others a *corollary,* &c.

CONSECUTIVE CHORDS, in *Muſic,* are ſuch as immediately ſucceed each other in compoſition or performance. See MUSIC, *Plate* IV. Holder truly obſerves, when ſpeaking of the rule in compoſition, which diſallows a ſucceſſion of octaves or fifths, except by contrary motion, that in ſtrictneſs the ſame applies to all conſecutive intervals whatever; but that the intermixture of major and minor thirds, and major and minor-ſixths in the ſcale, renders the occurrence of conſecutive major-thirds, major-ſixths, minor-thirds or minor-ſixths, very rare and inoffenſive in their cloying effect upon the ear, compared with thoſe of fourths, fifths, or octaves, if care is not taken by the compoſer to prevent the ſucceſſion of the latter, except in contrary motions.

CONSECUTIVELY, CONSECUTIVÉ, in the *School Philoſophy,* is ſometimes uſed in oppoſition to *antecedently,* and ſometimes to *effectively,* or *cauſally.*

Thus, ſay the ſchoolmen, the corruption of one thing is the generation of another, not *effectively,* but *conſecutively:* that is, ſince matter cannot be without form, it is neceſſary, that the generation of one thing follow upon the corruption of another.

CONSEDIA, in *Ancient Geography,* a place of Gallia Lyonnenſis, ſituated, according to the Itinerary of Antonine, between *Condate* and *Fanum Martio.*

CONSEIL DE GUERRE, Fr. *Council of War.* This is compoſed of the general in chief, and the general officers of the army, which he commands, whether it be held for the purpoſe of deliberating among themſelves on the meaſures they ought to purſue in a difficult conjuncture, of an offenſive or defenſive nature or otherwiſe; or for ſome act of military juſtice; or for accepting, regulating, ſtipulating, or refuſing articles of a propoſed capitulation; or for eſtabliſhing rules and regulations for the police and diſcipline of the troops; or, in fine, for judging of any military crime or offence.

CONSEIL *de Guerre ſecret,* Fr. A ſecret council of war. A ſecret council held by the king and his miniſters for deliberating on a defenſive, offenſive, or federative war.

CONSENT *of* PARTS, in the *Animal Economy.* See SYMPATHY.

CONSENTES, in *Mythology,* derived from the old Latin *conſo, to counſel,* denote twelve ſuperior deities among the Romans, or the "dii majorum gentium," who were apprehended to belong to the council of Jupiter. They were comprehended by Ennius in the following diſtricts:

> "Juno, Veſta, Minerva, Ceres, Diana, Venus, Mars,
> Mercurius, Jovis, Neptunus, Vulcanus, Apollo."

Thoſe which were eſteemed the ſuperior deities, and were the principal objects of the Pagan worſhip, had been men, according to Cicero (Taſcul. Diſput. lib. i. c. 12, 13.); and this was taught even in the myſteries. Varro mentions twelve deities under the ſame denomination, who ſuperintended agriculture. Lib. i. De Re Ruſtica.

Theſe conſentes had a temple at Piſa in Italy; and they had their common altar at Athens, as Plutarch (in Nicia) informs us. Ariſtophanes ſays, it was uſual to ſwear by them. In ancient inſcriptions they are thus marked; J.O.M. *i.e. Jovi optimo maximo,* CÆTERISQ. DIS CONSENTIBUS. They were alſo called "Dii magni," "cæleſtes," or "nobiles;" and are repreſented as occupying a different part of heaven from the inferior gods, who are called "Plebs."

CONSENTIA were feaſts inſtituted in honour of theſe deities.

CONSENTIA, in *Ancient Geography, Coſenza,* a town of Italy and capital of the country of the Brutii by whom it was built. It was ſituated on the ſmall river Crathis. Alexander, king of Epirus, ſurpriſed it in his expedition into Italy. See COSENZA.

CONSEQUENCE, in *Logic,* the concluſion of a reaſoning, or argument.

The two premiſes of a ſyllogiſm being granted, the conſequence muſt alſo be granted.

In a more reſtrained ſignification, conſequence is uſed for the relation or connexion between two propoſitions, whereof one follows, or is inferred, from the other.—Thus: *It is an animal, and therefore feels.*

CONSEQUENT, the laſt propoſition of an argument; being ſomething deduced or gathered from a preceding argumentation. An enthymeme only contains two propoſitions, the *antecedent* and *conſequent:* if the *antecedent* be abſurd, the *conſequent* muſt be ſo too.

Consequent, in a more preciſe ſenſe, is uſed for the propoſition which contains the concluſion, conſidered in itſelf, and without any regard to the *antecedent:* in which ſenſe, the *conſequent* may be true, though the *conſequence* be falſe.

Consequent *of a ratio*, in *Arithmetic*, the latter of the two terms of a ratio: or that to which the antecedent is referred. See Proportion.

Thus, in $a : b$, or a to b, b is the conſequent, a the antecedent.

CONSEQUENTS, in *Rhetoric*, are alſo uſed to ſignify ſuch things, as being allowed, neceſſarily, or very probably, infer their antecedents. Thus with reſpect to a ſubſtance, it is corruptible, and therefore material.

CONSEQUENTE, in the *Italian Muſic*, is uſed to ſignify concords, or thoſe intervals which afford pleaſure, be they either perfect, as the fifth and eighth, or imperfect, as the third, ſixth, &c. See Octave.

CONSEQUENTIA, in *Aſtronomy*, is oppoſed to *antecedentia;* and a motion *in conſequentia* is a motion in the order of the ſigns of the zodiac.

CONSEQUENTIAL Damages, in *Law*. See Damage.

CONSEQUENZA, *Ital.* a term in *Muſic*, uſed by Zarlino and other old authors, inſtead of *Fuga;* but P. Martini makes it ſynonymous with *Ripoſta*, or reply to a ſubject given.

CONSERANS, or Conferans, in *Geography*, the name, before the revolution, of a country in France, in Gaſcony, and the dioceſe of a biſhop, who reſided at St. Liſier, the capital; it was bounded on the eaſt by Foix, on the ſouth by Catalonia, and on the north and weſt by Comminges.

CONSERVATION, in *Ontology*, denotes giving duration, or continuance in exiſtence to all creatures, in contradiſtinction to creation, which gives exiſtence to all created ſubſtances. Some of the ancient ſchoolmen have repreſented conſervation as a continued creation; to which it has been objected that as God, whenever he creates a ſubſtance, muſt create it with all the properties, modes, and accidents which belong to it, it will follow, that he muſt at the ſame time create or give being to, all their ſinful thoughts and inclinations, and even their moſt criminal and abominable actions; or, in the moſt complete ſenſe of the term, be the author of ſin. Watts's Philoſ. Eſſ. Eſſ. xi § 4.

CONSERVATIVE Suture. See Suture.

CONSERVATOR, an officer eſtabliſhed for the ſecurity and preſervation of the privileges granted to ſome cities and communities; or, a perſon who has a commiſſion to judge of, and decide, the differences ariſing among them. In moſt catholic univerſities, there are two *conſervators;* the *conſervator* of royal privileges, or thoſe granted by kings; and the *conſervator* of apoſtolical privileges, or thoſe granted by the pope. The firſt takes cognizance of perſonal and mixed cauſes between the regents, ſtudents, &c. and the latter of ſpiritual matters between eccleſiaſtics.

Anciently there were appointed *conſervators* of treaties of peace between princes; and theſe conſervators became judges of the infractions made on a treaty, and were charged with procuring ſatisfaction to be made. They were uſually the feudatories of the ſeveral powers. In lieu of conſervators, princes now have recourſe to other indifferent princes to guarantee their treaties. See Guarantee.

Conservator *of the peace*, in our *Ancient Cuſtoms*, was a perſon who had an eſpecial charge, by virtue of his office, to ſee the king's peace kept.

Till the erection of juſtices of the peace by king Edward III. there were ſeveral perſons who by common law were intereſted in keeping the ſame: ſome having that charge as incident to other offices; and others ſimply, or of itſelf, called *cuſtodes*, or *conſervators of the peace.* Thoſe that were ſo by virtue of their office ſtill continue; but the latter are ſuperſeded by the modern juſtices.

The chamberlain of Cheſter is ſtill a *conſervator* in that county: by virtue of his office. 4 Inſt. 212.

Sheriffs of counties at common law are conſervators of the peace; and conſtables, by the common law, were conſervators, but ſome ſay they were only ſubordinate to the conſervators of the peace, as they now are to the juſtices.

The king's majeſty is, by his office and dignity royal, the principal conſervator of the peace within all his dominions; and may give authority to any other to ſee the peace kept, and to puniſh ſuch as break it: hence it is uſually called "the king's peace." The lord chancellor, or keeper, the lord treaſurer, the lord high ſteward of England, the lord mareſchal, the lord high conſtable of England, (when any ſuch officers are in being,) and all the juſtices of the court of King's Bench (by virtue of their offices,) and the maſter of the rolls (by preſcription) are general conſervators of the peace throughout the whole kingdom, and may commit all the breakers of it, or bind them in recognizances to keep it. The other judges are only ſo in their own courts. The coroner is alſo a conſervator of the peace within his own county; as is alſo the ſheriff; and both of them may take a recognizance or ſecurity for the peace. Conſtables, tithing-men, and ſuch like, are alſo conſervators of the peace within their own juriſdiction; and may apprehend all breakers of the peace, and commit them till they find ſureties for their keeping it.

Thoſe that were, without any office, ſimply and merely conſervators of the peace, either claimed that power by preſcription, or were bound to exerciſe it by the tenure of their lands; or, laſtly, were choſen by the freeholders in full county court before the ſheriff; the writ for their election directing them to be choſen "de probioribus et potentioribus comitatus ſui in cuſtodes pacis." But when queen Iſabel, the wife of Edward II., had contrived to depoſe her huſband by a forced reſignation of the crown, and had ſet up his ſon Edward III., in his place, this being an unprecedented meaſure, cauſed an alarm; and, therefore, in order to prevent any inſurrections, and diſturbance of the peace, the new king ſent writs to all the ſheriffs of England, vindicating the manner of his obtaining the crown, and commanding each ſheriff to keep the peace throughout his bailiwick, on pain and peril of diſinheritance and loſs of life and limb. Soon after it was ordained in parliament, that for the better maintaining and keeping of the peace in every county, good men and lawful, who were no maintainers of evil, or barretors in the country, ſhould be aſſigned to keep the peace. Thus, and at this time, the election of conſervators of the peace was taken from the people, and given to the king; ſuch aſſignment being conſtrued to be by the king's commiſſion. Nevertheleſs, they were ſtill called only conſervators, wardens, or keepers of the peace, till the ſtatute 34 Edw. III. c. 1. gave them the power of trying felonies; and then they acquired the more honourable appellation of juſtices. Blackſt. Comm. vol. i. See JUSTICE.

CONSERVATOR *of the truce and ſafe conducts; conſervator induciarum & ſalvorum regis conductuum*, was an officer appointed in every ſea-port, under the king's letters patent. His charge was to enquire of all offences committed againſt the king's truce and ſafe conducts, upon the main ſea, out of the franchiſes of the cinque-ports, as the admirals were wont to do, and ſuch other things as are declared in ſtatute 2 Hen. V. ſt. 1. cap. 6.

Two men learned in the law of the land were joined to ſuch conſervators, for hearing and determining according to that law the ſame treaſons, when committed within the body of any county. The above-cited ſtatute, ſo far as it made theſe offences amount to treaſon, was ſuſpended by 14 Hen. VI. c. 8., and repealed by 20 Hen. VI. c. 11., but revived by 29 Hen. VI. c. 2., which gave the ſame powers to the lord chancellor, aſſociated with either of the chief juſtices, as belonged to the conſervators of truce and their aſſeſſors; and enacted that, notwithſtanding the party be convicted of treaſon, the injured ſtranger ſhould have reſtitution of his effects, prior to any claim of the crown. See SAFE *Conduct.*

CONSERVATORIO, *Ital.* a title given in Italy to almoſt all charity-ſchools; but chiefly to thoſe where children are taught muſic, and are otherwiſe educated with a view to that profeſſion. The *conſervatorios* of the city of Venice have been much celebrated by all travellers previous to the revolution: it had four of theſe ſchools: the *Oſpidale della Pietà*, the *Mendicanti*, the *Incurabile*, and the *Oſpidaletto a S. Giovanni e Paulo*, at each of which there was a performance every Saturday and Sunday evening, as well as on great feſtivals. At theſe, the performers, both vocal and inſtrumental, were all girls; the organ, violins, flutes, violoncellos, baſſoons, and even double-baſes, kettle-drums, and French-horns, were ſupplied by females. Each of theſe eſtabliſhments was a kind of foundling hoſpital for natural children and orphans, under the protection of ſeveral nobles, citizens, and merchants, who, though the revenue is very great, yet contribute annually to its ſupport. Theſe girls are maintained here till they are married, and all thoſe who have talents for muſic are taught by the beſt maſters of Italy.

There were three conſervatorios in the city of Naples, for the education of boys who were intended for the profeſſion of muſic, of the ſame kind with thoſe of Venice, for girls. As the ſcholars in the Venetian conſervatorios have been juſtly celebrated for their taſte and neatneſs of execution, ſo thoſe of Naples have long enjoyed the reputation of being the firſt *contra-puntiſts*, or compoſers in Europe. It is from theſe ſeminaries that Italy, and all Europe, have been delighted with the genius and talents of the two Scarlattis, Vinci, Leo, Pergoleſi, Porpora, Farinelli, Cafarelli, Gizziello, Durante, Jomelli, Perez, Piccini, Trueta, Anfoſſi, Sacchini, Paeſiello, and innumerable others of the firſt eminence among compoſers and performers both vocal and inſtrumental.

CONSERVATORY, in *Gardening*, a place conſtructed ſomewhat in the manner of the green-houſe, but more ſpacious and elevated, and finiſhed in a neater and more perfect manner; being deſigned for containing and preſerving the more rare and curious ſorts of exotic plants, as well as for affording amuſement by being provided with walks laid with ſome ſort of neat material, according to the taſte of the proprietor, in a ſerpentine or other irregular manner between the plants.

Houſes of this nature ſhould have dry and rather elevated ſituations, at a ſmall diſtance from the reſidence, and be ranged in ſuch a manner as to have the benefit of the ſun as much as poſſible during the day. They muſt likewiſe be provided with flues for the purpoſe of communicating fire heat when it may be neceſſary, and alſo valves and other contrivances for the introduction of freſh air when wanted, and to afford due ventilation.

The ſides, ends, and roofs, muſt be formed with glaſs, as in the green-houſe, in order to admit light freely, and at the ſame time protect the plants.

It has been generally conſidered as ſynonymous with green-houſe, but its principle or eſſential difference conſiſts in this, that in the latter the trees and plants are either in tubs or pots; and placed on ſtands or ſtages through the winter till they are removed into ſome ſheltered ſituation abroad for the ſummer; while in the former the ground plan is laid out in beds and borders made up of the fineſt compoſitions of ſoils or of earthy materials that can be procured, three or four feet in depth; in which the trees and plants, taken out of their tubs or pots, are regularly planted, in the ſame manner as hardy plants in the open air. And inſtead of taking out the plants in the ſummer, as in the green-houſe, the whole of the glaſs roof is taken off, and the plants expoſed to the open air; when on the approach of autumn-froſts the lights are again put on, and remain ſo till the ſtate of the ſeaſon is ſuch as that they can be removed again without danger from cold.

In caſes of neceſſity, it is evident however that theſe buildings may alſo be uſed as green-houſes by introducing ſtages inſtead of beds, in which caſe the glaſs-roof ſhould be fixed. Other conveniences may be attached to them, ſuch as retiring rooms, ſeed rooms, aviaries, &c. Some buildings of this ſort are, according to the editor of Miller's dictionary, formed ſo as to have one of the wings facing the ſouth-eaſt, and the other the ſouth-weſt, ſo that from the time of the ſun's firſt appearance upon any part of the building, until it goes off at night, it may be conſtantly reflected from one part to the other, and the cold winds be alſo kept off from the front of the centre building. In the area of the adjoining rooms or wings, many of the more tender exotic plants may be placed in the ſummer ſeaſon and in the ſpring before the plants can be ſet out. The beds and borders of this area may be full of anemonies, ranunculuſes, early tulips, &c. which will be paſt flowering, and the roots fit to take out of the ground, by the time the plants are taken out of the houſe. In the centre of this area may be a ſmall baſon of water, which will be very convenient for watering the plants, not only on account of its nearneſs, but becauſe the water will be ſoftened and warmed by the reflection from the glaſſes. And the wing facing the ſouth-eaſt ſhould always be preferred for the warmeſt, or bark-ſtove, becauſe the ſun, at its firſt appearance in the morning, ſhines directly upon the glaſſes, and warming the air of the houſe, gives new life to the plants, after the long nights of the winter ſeaſon.

It is alſo farther obſerved, that in theſe buildings, if there are not ſheds running behind them their whole length, the walls ſhould not be leſs than three bricks thick, and if they are even more it will be better, becauſe where the walls are thin and expoſed to the open air, the cold will penetrate; and when the fires are made the heat comes out through the walls, ſo that it will require a larger quantity of fuel to maintain a proper temperature of warmth in the houſes; and in general, the cloſer and better theſe houſes are built, the leſs fuel will be required to warm them, ſo that the firſt expence in building them properly will be the cheapeſt, where the after expence of fires is taken into the account.

The ground plan and elevation of an elegant and very convenient improved houſe of this ſort may be ſeen in the appropriate plate.

CONSERVATORY is ſometimes uſed for a place to preſerve ſnow and ice. See Phil. Tranſ. N° 8. p. 140. See ICE-*Houſe.*

CONSERVE, in *Pharmacy*, &c. a dry confect, or form of medicine, or food, contrived to preſerve the flowers, leaves, roots, peels, or fruits of ſeveral ſimples, as near as poſſible to what they were when freſh-gathered; and to give them an agreeable taſte.

Conſerves are compoſitions of recent vegetable matters and ſugar beaten together into an uniform maſs. Vegetables whoſe virtues are ſoon loſt by drying, may be preſerved in this manner for a conſiderable time unimpaired, the ſugar preventing the natural decompoſition and moulding which would otherwiſe take place.

The preparation of the conſerves is as ſimple as poſſible. The ſugar is firſt ground to fine powder, and then mixed by long beating (not by ſolution) with the vegetable pulp or other material. No heat or other mode of preparation is employed, ſo that the vegetable matter remains as nearly as poſſible in the ſtate in which it exiſted in the plant at the moment of gathering. The conſerves directed by the London college are thoſe of hips, roſes, ſloes, arum and ſquills. Of theſe the two laſt alone can be conſidered as active medicines; and the arum is exhibited with peculiar efficacy in this form, as its pungency to the palate is a little ſheathed, whilſt its internal ſtimulating powers remain unaltered.

The *conſerve of arum*, or cuckow-pint, is a compoſition of arum bruiſed, half a pound, and double refined ſugar, $1\frac{1}{2}$ pound, beaten together in a mortar. Thoſe who hold in veneration the integrity and experience of Sydenham, will have no doubt of the effects of this medicine in rheumatic caſes. This conſerve may be given to adults in doſes of a dram.

The *conſerve of the hip*, or "conſerva cynoſbati," is formed by mixing one pound of hips with 20 ounces, by weight, of double refined ſugar, powdered. This pulp ſhould be ſeparated with great care from the rough prickly matter incloſing the ſeeds; a ſmall quantity of which, retained in the conſerve, is apt to occaſion an uneaſineſs at the ſtomach, a pruritus about the anus, and ſometimes vomiting.

The *conſerve of the ſloe*, "conſerva pruni ſylveſtris," is prepared by putting the ſloes in water upon the fire, that they may ſoften, taking care that they do not burſt; then taking them out of the water, preſſing out the pulp, and mixing it with three times its weight of double refined ſugar.

The *conſerve of ſquills*, "conſerva ſcillæ," is made by beating together in a mortar one ounce by weight of freſh ſquill with five ounces by weight of double refined ſugar. This conſerve is directed to be prepared in a ſmall quantity, in order to guard againſt its variation in ſtrength. It may be given to adults, from half a dram to two ſcruples, or more; eſpecially when freſh.

For the *conſerve of ſea-worm-wood*, the outer rind of the *Seville orange*, *wood-ſorrel*, and of the *red roſe;* pluck the leaves from the foot-ſtalks, and the unblown petals from the calyx, cutting off the heels: take off the outer rind of the oranges with a grater: when you have thus prepared them, bruiſe them with a wooden peſtle in a marble mortar; and then beat them up with three times their weight of double-refined ſugar, until they are mixed. The ſugar ſhould be powdered by itſelf, and paſſed through a ſieve, before it is mixed with the vegetable maſs; otherwiſe it cannot be properly incorporated. Roſe buds, and ſome other vegetables, are uſually prepared for mixing with ſugar by a ſmall wooden mill, contrived for that purpoſe. All the conſerves are to be kept in cloſe veſſels, eſpecially thoſe of arum and ſquill.

With regard to fruits, as currants, &c. they ſet them on the fire to make them yield their juice, then drain and ſtrain them, and thicken what comes from them over the fire, and add to it the ſugar. This laſt ſort of conſerve is particularly called a *jelly;* which ſee.

CONSERVES, Fr. in *Military Language.* See COUNTER-GUARD, or *contre-garde*, the names by which this work is uſually and beſt known.

CONSET'S BAY, in *Geography*, a bay on the N.E. coaſt of the iſland of Barbadoes, N. of Conſet's point, which is a cape, 10 miles N.E. of Bridge-town.

CONSETTI, ANTONIO, in *Biography*, an hiſtorical painter, native of Modena, where he enjoyed conſiderable reputation, in the laſt century. He was born in the year 1686, and is ſaid to have been ſucceſſively the diſciple of his countrymen Franceſco Stringa, and Donato Creti of Bologna, from whoſe precepts and example he acquired a correct ſtyle of drawing, and facility of compoſing. Unfortunately, however, his colouring is deſtitute of thoſe charms of union and ſoftneſs, which captivate the eye at firſt ſight. The principal part of the life of this artiſt was ſpent in the ſtate of Modena, where his pictures are by no means uncommon, and where he died in 1766. Lanzi. Storia Pittorica.

CONSIDERATIO CURIÆ, in *Law*, terms often occurring in law proceedings, and where matters are determined by the court. "Ideo conſideratum eſt per curiam," *i. e.* therefore it is conſidered and adjudged by the court. *Conſideratio curiæ*, &c. denotes the judgment of the court.

CONSIDERATION, the material cauſe, or *quid pro quo*, of any contract, and without which no contract is obligatory or binding.

This conſideration is either *expreſſed*; as if a man bargain to give ten guineas for a horſe, or to ſell his land for a certain ſum, or to grant it in exchange for other lands, &c.; or when a perſon agrees for a ſtipulated ſum to do a thing: or *implied*, when the law itſelf enforces a conſideration; as if a man coming into an inn, take meat, drink, and lodging for himſelf and horſe, the law preſumes he intends to pay for them, though there be no expreſs contract between him and his hoſt: and if he diſcharge not the houſe, the hoſt may ſtop his horſe.

Conſiderations may be regarded either as pertaining to *contracts* generally, or to *deeds* in particular. As to *contracts*, conſideration may be defined to be the reaſon which moves the contracting party to enter into the contract. The civilians hold, that in all contracts, either expreſs or implied, there muſt be ſomething given in exchange, or ſomething that is mutual or reciprocal. This thing, which is the price or motive of the contract, is called the conſideration; and it muſt be a thing lawful in itſelf, or elſe the contract is void. A *good* conſideration is that of blood or natural affection between near relations; the ſatisfaction accruing from which the law eſteems an equivalent for whatever benefit may move from one relation to another. (3 Rep. 83. 1 Inſt. 271. 1 Rep. 176.) This conſideration may ſometimes, however, be ſet aſide, and the contract become void, when it tends in its conſequences to defraud creditors or other third perſons of their juſt rights. But a contract for any *valuable* conſideration, as for marriage, for money for work done, or for other reciprocal conſiderations, can never be impeached at law; and, if it be of a ſufficient adequate value, is never ſet aſide in equity: for the perſon contracted with has then given an equivalent in recompence, and is therefore as much an owner, or a creditor, as any other perſon. Theſe valuable conſiderations are divided by the civilians into four ſpecies. 1. *Do, ut des;* as when I give money or goods on a contract to receive in return money or goods: of this kind are all loans of money upon bond, or promiſe of repayment, and all ſales of goods, in which there is an expreſs contract to pay ſo much for them, or elſe the law implies a contract to pay as much as they are worth. 2. *Facio, ut facias;* as when I agree with a man to do his work for him, provided that he will do mine for me; or if two perſons agree to intermarry; or to do any other poſitive acts on both ſides: or, to forbear on one ſide on conſideration of ſomething done on the other, as that in conſideration A, the tenant, will repair his houſe, B, the landlord, will not ſue him for waſte: or, for mutual forbearance on both ſides. 3. *Facio, ut des;* as, when a man agrees to perform any thing for a price, either ſpecifically mentioned, or left to the determination of the law to ſet a value on it. Thus, when a ſervant hires himſelf to his maſter for agreed wages, he contracts to ſerve his maſter for that ſpecific ſum: or, otherwiſe, if he be hired generally, he is under an implied contract to perform this ſervice for its reaſonable worth. 4. *Do, ut facias;* as, when I agree with a ſervant to give him ſuch wages upon his performing ſuch work, which is the laſt ſpecies inverted; for *ſervus facit, ut herus det,* and *herus dat, ut ſervus faciet.*

A conſideration of ſome ſort or other is ſo abſolutely neceſſary to the forming of a contract, that a *nudum pactum*, or agreement to do or pay any thing on one ſide, without any compenſation on the other, is totally void in law; and a man cannot be compelled to perform it. (Dr. and Stud. l. 2. c. 24.) Thus, if one man promiſes to give another 100 *l.*, nothing is contracted for or given on the one ſide, and therefore nothing is binding on the other. And, however a man may or may not be bound to perform it, in honour or conſcience, which the municipal laws do not decide; thoſe laws will certainly not compel the execution of what he had no viſible inducement to engage for; and, therefore, our law has adopted the maxim of the civil law, that "ex nudo pacto non oritur actio." But any degree of reciprocity will prevent the pact from being nude; nay, if even the thing be founded on a prior moral obligation (as a promiſe to pay a juſt debt, though barred by the ſtatute of limitations), it is no longer *nudum pactum*. And as this rule was principally eſtabliſhed to avoid the inconvenience that would ariſe from ſetting up mere verbal promiſes, for which no good reaſon could be aſſigned, it therefore does not hold in ſome caſes, where ſuch promiſe is authentically proved by written documents. For if a man enters into a voluntary bond, or gives a promiſſory note, he ſhall not be allowed to aver the want of a conſideration in order to evade the payment; for every bond from the ſolemnity of the inſtrument, and every note from the ſubſcription of the drawer, carries with it an internal evidence of a good conſideration. Courts of juſtice will therefore ſupport them both, as againſt the contractor himſelf; but not to the prejudice of creditors or ſtrangers to the contract. Plowd. 308, 309. Hard. 4. 1 Ch. Rep. 157. Ld. Raym. 760. Fonblanque, Treat. Eq. 334. *n.*). See CONTRACT.

With regard to *deeds*, it may be obſerved, that they muſt be founded upon good and ſufficient conſideration; not upon an uſurious contract (ſtat. 13 Eliz. c. 8.); nor upon fraud or colluſion, either to deceive purchaſers *bona fide* (ſtat. 27 Eliz. c. 4.), or juſt and lawful creditors (ſtat. 13 Eliz. c. 5.); any of which bad conſiderations will vacate the deeds, and ſubject ſuch perſons as put the ſame in uſe, to forfeitures, and often to impriſonment. A deed alſo, or other grant made without any conſideration, is, as it were, of no effect; for it is conſtrued to enure or to be effectual, only to the uſe of the grantor himſelf. (Park. § 533.). The conſideration may be either a *good* or a *valuable* one. A good conſideration is ſuch as that of blood, or of natural love and affection, when a man grants an eſtate to a near relation; being founded on motives of generoſity, prudence, and natural duty. A valuable conſideration is ſuch as money, marriage, or the like, which the law eſteems an equivalent given for the grant (3 Rep. 83.); and is therefore founded in motives of juſtice. Deeds made upon good conſideration only, are conſidered as merely voluntary, and are frequently ſet aſide in favour of creditors, and *bona fide* purchaſers. See DEED.

A mere voluntary curteſy will not be a good conſideration of a promiſe; but the value and proportion of the conſideration is not material for maintaining an action, whether it be a penny or 100 *l.*; but a jury will give damages proportionable to the loſs. (Hob. 5. 10 Rep. 76.) A conſideration that is void in part, is void in the whole; and if two conſiderations be alleged, and one of them is found falſe by the jury, the action fails. (Hob. 126. Cro. Eliz. 848.) But if there be a double conſideration for the grounding of a promiſe, for the breach of which an action is brought; though one of the conſiderations be not good, yet if the other be good, and the promiſe broken, the action will lie upon that breach; for one conſideration is ſufficient to ſupport the promiſe. (1 Lill. 297.) A conſideration muſt be lawful, to ground an *aſſumpſit.* (2 Lev. 161.) Where conſiderations are valuable, and conſiſt of two or more parts, there the performance of every part ought to be ſhewn. (Cro. Eliz. 579.) In caſe a deed of feoffment be made of lands, or a fine and recovery be paſſed, and no conſideration is expreſſed in the deed, &c. for the doing thereof, it ſhall be intended by the law, that it was made in truſt for the uſe of the feoffer or conuſor; for it ſhall be preſumed he would not part with his land without a conſideration; and yet the deed ſhall be conſtrued to operate ſomething, and that which is moſt reaſonable. (4 Lill. Abr. 299.) Blackſt. Com. vol. ii. Jacob's Law Dict. by Tomlins.

CONSIGLIONE, in *Geography*, a town of the iſland of Sicily, in the valley of Mazar; 19 miles S. of Palermo.

CONSIGNE, Fr. parole or counter-ſign. When uſed in the maſculine gender, it alſo means a perſon formerly paid by the French government for reſiding conſtantly in a garriſoned town in order to take cognizance of all perſons that entered by the gates or went out of them. He had a place allotted to him, and regularly delivered a report to the governor or commandant of the place.

CONSIGNÉ. A perſon who could not paſs the poſt, or quit the houſe, to which the order of his ſuperior had conſigned him.

CONSIGNMENT, or **CONSIGNATION**, the depoſiting any ſum of money, bills, papers or commodities, in ſure hands; either by order of a court of juſtice, in order to their being delivered to the perſons to whom they are adjudged; or voluntarily, in order to their being remitted to the perſons they belong to, or ſent to the places they are deſtined for.

CONSIGNMENT *of goods*, is the delivering or making them over to another. Thus goods are ſaid to be conſigned to a factor, when they are ſent to him to be ſold, &c. or when a factor ſends back goods to his principal, they are ſaid to be conſigned to him.

CONSILINUM, in *Ancient Geography*, a town of Italy, in a gulf between Brutium and Zephyrium, according to P. Mela. Frontinus ſays, that it was a Roman colony, and places it in Lucania.

CONSILIUM, *dies conſilii*, in *Law*, was a time allowed for the accuſed to make his defence, and to anſwer the charge of the accuſer. It is now uſed for a ſpeedy day appointed to argue a demurrer; which the court grants after a demurrer joined, on reading the record of the cauſe. See IMPARLANCE.

CONSIMILI CASU. See CASU.

CONSISTENCE, a ſtate of reſt, wherein things capable of growth or decreaſe, continue for ſome time at a ſtand, without either.

This term is particularly uſed with regard to trees, for the time, or age, beyond which they do not grow, and yet at which they do not decline.

Thus we diſtinguiſh three ſtates or ſtages of a tree; its growth, conſiſtence, and return: and theſe are common to all trees, even fruit trees.

The conſiſtence of an oak is from fifty to a hundred and ſixty years: ſome, however, hold, that their conſiſtence only commences from a hundred years; aſſerting that they grow till that time, and that they continue in that ſtate of perfection to two hundred years of age.

CONSISTENCE, in *Phyſics*, is that ſtate of a body wherein its component particles are ſo connected, or entangled among themſelves, as not to ſeparate or recede from each other.

Conſiſtence only differs from continuity in this, that conſiſtence implies a regard to motion or reſt, which continuity does not; it being ſufficient to denominate a thing continuous, that its parts are contiguous to each other.

When uſed relative to a diſeaſe, it imports the criſis or acme thereof: when applied to the humours, excrements, or excretions, it imports their ſtate as to thickneſs or thinneſs.

CONSISTENCE is particularly uſed with regard to bodies conſidered as they are more ſoft, or more hard, more liquid, or more dry.

Forms of medicines, as electuaries, lambatives, boluſes, ſyrups, unguents, &c. differ chiefly in conſiſtence.

Not only the gratefulneſs, but alſo the operation, of medicines, depend in ſome meaſure on their conſiſtence; for medicines of a thick conſiſtence are taken into the ſtomach, and penetrate into the body with greater difficulty than ſuch as are thin and liquid; and it requires more trouble to ſwallow a thick than a thin medicine: for this reaſon thick medicines are generally nauſeous and ungrateful; and this is the reaſon why cathartic boluſes are often diſſolved in ſome agreeable liquor, ſince in this form they are more grateful than in any other: for this reaſon alſo apozems are generally clarified by whites of eggs, or a ſtrainer.

On the contrary, a thick conſiſtence is on ſome occaſions more to be deſired; in ulcers of the aſpera arteria, and œſophagus, for inſtance, where we muſt give medicines made up with gum tragacanth, or other ſubſtances of a like nature, which by their viſcidity fix the medicines, as it were, longer to the part affected.

CONSISTENT *Bodies*, is a term uſed by Mr. Boyle, for ſuch as we ordinarily call *firm*, or *fixt bodies*; in oppoſition to *fluid* ones.

That author has a particular eſſay on the *atmoſphere of conſiſtent bodies*; wherein he ſhews, that all, even ſolid, hard, ponderous and fixed bodies, do exhale or emit effluvia to a certain ſpace all around them.

CONSISTENTES, in *Church Hiſtory*, a kind of penitents who were allowed to aſſiſt at prayers, but could not be admitted to receive the ſacrament.

CONSISTORIAL *Advocate*. See ADVOCATE.

CONSISTORY, or *Roman* CONSISTORY, denotes the college of cardinals: or the pope's ſenate, and council, before whom judiciary cauſes are pleaded.

Du-Cange derives the word from *conſiſtorium*; i. e. *locus ubi conſiſtitur*; uſed chiefly for a veſtible, gallery, or antechamber, where the courtiers wait for admiſſion; and called *a conſiſtente multitudine*.

The conſiſtory is the firſt court, or tribunal of Rome: it never meets but when the pope pleaſes to convoke it: the pope preſides in it in perſon, mounted on a magnificent throne, and habited in his *pontificalia*; on the right are the cardinal biſhops and prieſts, and on the left the cardinal deacons.

The place where it is held, is a large hall in the apoſtolical palace, where princes and ambaſſadors of kings are received. The other prelates, prothonotaries, auditors of the rota, and other officers, are ſeated on the ſteps of the throne: the courtiers ſit on the ground; ambaſſadors on the right, and conſiſtorial and fiſcal advocates behind the cardinals.

Beſides the public conſiſtory, there is alſo a private one, held in a retired chamber, called the chamber of *papegay*; the pope's throne here being only raiſed two ſteps high.

Nobody is here admitted but the cardinals, whoſe opinions are collected, and called *ſentences*. Here are firſt propoſed and paſſed all bulls for biſhoprics, abbeys, &c. Hence biſhoprics, and abbeys, are ſaid to be conſiſtorial benefices; in regard, they muſt be propoſed in the conſiſtory, the annates be paid to the pope, and his bulls taken.

Anciently they were elective; but by the concordat, which aboliſhes elections, they are appointed to be collated by the pope alone, on the nomination of the prince.

CONSISTORY was alſo the name of a court under Conſtantine, where he ſat in perſon, and heard cauſes: the members of this court were called *comites*.

CONSISTORY is alſo uſed among the reformed, for a council or aſſembly of miniſters and elders, to regulate their affairs, diſcipline, &c.

CONSISTORY, or *Court Chriſtian*, in the *Engliſh Laws*, is a council of eccleſiaſtical perſons, or the place of juſtice in an eccleſiaſtical or ſpiritual court.

Every archbiſhop and biſhop has a conſiſtory-court, held, before his chancellor or commiſſary, who is the judge, and ſuppoſed to be ſkilled in the civil and canon law, either in his cathedral, or in ſome other convenient place of his dioceſe, for eccleſiaſtical cauſes, ariſing within their reſpective dioceſes. In places of the dioceſe, far diſtant from the biſhop's conſiſtory, the biſhop appoints a commiſſary, *commiſſarius foraneus*, to judge in all cauſes within a certain diſtrict, and regiſter to enter his decrees, &c. (2 Rol. Abr. 286. Seld. Hiſt. Tithes, 413, 414.) The ſpiritual court was anciently, in the time of the Saxons, joined with the county or hundred court; and the original of the conſiſtory court, as divided from thoſe courts, is found in a law of the Conqueror, quoted by lord Coke.

From this court there lies an appeal to the archbiſhop of each province reſpectively, by virtue of ſtat. 24 Hen. VIII. c. 12.

CONSOLATION, one of the places in *Rhetoric*, wherein the orator endeavours to abate and moderate the grief or concern of another.

In conſolation, a principal regard is to be had to the circumſtances and relations of the parties. Scaliger conſiders this exceeding well, De Arte Poetica. "The conſolator, ſays he, is either a ſuperior, an inferior, or an equal; with regard, either to preferment, honour, wealth, wiſdom, or age. Livia is therefore to comfort Ovid, in a manner very different from that wherein Ovid comforts Livia. Thus, as to authority, a father and ſon, Cicero and Pompey, are to conduct their conſolations very differently: ſo in wealth; as if a client ſhould undertake to comfort Craſſus: in wiſdom; as when Seneca comforts Polybius and his mother: as to age, there need no examples."

"A ſuperior may interpoſe his authority, and may even chide; a wiſe man may even diſpute; ſentences will become him. An inferior is to ſhew reſpect and affection, and own he had this from ſome wiſe or learned perſon: an equal to appeal to their common friendſhip."

CONSOLE, in *Architecture*, a bracket or projecting body commonly in the ſhape of the letter S, which is uſed to ſupport a cornice, vaſe, buſt, ſtatue, or even a column, as in the barbarous architecture of the Diocletian palace at Spalatro. Corbel is eſſentially the ſame thing as conſole, but is generally confined to the deſcription of Gothic building.

CONSOLIDA, in *Botany*, Major; Bauh. Pin. See Symphytum *officinale*.

Consolida *media*; Bauh. Pin. See Ajuga.

Consolida *paluſtris*; Taber. See Senecio *paluſtris*.

Consolida *regalis*; Bauh. Pin. Taber. Mons. See Delphinium.

CONSOLIDATION, in *Law*, the combining and uniting of two benefices into one; ſtat. 37 Hen. VIII. cap. 21. which union is to be by the aſſent of the ordinary, patron, incumbent, &c. and to be of ſmall churches lying near together.

The term is borrowed from the civil law; where it properly ſignifies an union of the poſſeſſion, or occupation, with the property. Thus, if a man hath by legacy *uſufructum fundi*, and afterwards buys the property, or fee-ſimple, of the heir; this is called a conſolidation.

Consolidation, in *Surgery*, is the proceſs of nature, by which a ſolution of continuity is united, either in a ſoft or hard part of the body; and, as this proceſs was formerly ſuppoſed to be within the controul of ſurgeons, the remedial applications employed for that purpoſe were denominated *conſolidating medicines*, or *ſarcotics*. Of this kind were the different balſamic and reſinous unguents, with all the ſtimulating compoſitions containing turpentine. The ſurgeon may certainly vary the ingredients of his dreſſings in ſuch a manner as to change the ſurface of a ſore, and, in many caſes, ſo as to occaſion a healing proceſs; but, after all, he acts only as the hand-maid of nature, and is unable to advance one ſtep towards the conſolidation of a wound, unleſs there be a previous tendency in the part to heal.

Warm ſtimulating applications will indeed cauſe a flow of blood to the part whereon they are applied; and by exciting the healthy action of blood-veſſels, as well as by increaſing the ſenſibility of the ſkin or adjacent ulcerated ſurface, they may promote ſuppuration, and even contribute to effect a cure, where it ſeemed unlikely before. In this ſenſe of the term, therefore, we may admit the exiſtence of conſolidating remedies.

CONSONANCE, in *Grammar*, denotes a like cadence, or cloſe of words, periods, &c.

Conſonances are ordinarily faults in diſcourſe, eſpecially in Engliſh proſe: though the ancients make a figure of them, which they call ὁμοιοτέλευτον. Too great a conſonancy in the rhymes has always an ill-effect.

Consonance, in *Muſic*, ſignifies the union or agreement of two ſounds produced at the ſame time, and in this ſenſe, it includes all ſorts of muſical intervals, which naturally divide themſelves into three kinds, *viz.* 1ſt. Concords, or ſuch as produce an agreeable and pleaſing effect upon the ear; ſee that article. 2d. Imperfect or tempered concords, which are intervals nearly related to concords in reſpect to their poſition in the ſcale, as explained when we were treating of perfect concords, and alſo in partaking ſomewhat of the pleaſing effect of the concords to which they belong, when not too much tempered; theſe are alſo further diſtinguiſhed by the phenomena of Beats, ſee that article; and Imperfect *Concords*: and 3d. Diſcords, which are intervals that have a grating or diſagreeable jarring effect upon the ear, or ſometime a fluttering roughneſs when nearly equal to an imperfect concord, or to certain intervals in the ſcale, as the tones major and minor, the tritone, ſemidiapente, and others, as mentioned in relating Dr. Robiſon's experiments upon the concords. See Discord and Flutter. Conſonance, conſidered as ſignifying a ſound ariſing from ſeveral others ſounding together, whether agreeable or diſagreeable to the ear, may be divided into *concord* and *diſcord*. On this principle, Dr. Holder defines *conſonancy*, "A paſſage of ſeveral tunable ſounds through the medium, frequently mixing and uniting in their undulated motions, cauſed by the well-proportioned commenſurate vibrations of the ſonorous bodies, and conſequently arriving ſmooth and ſweet, and pleaſant to the ear; as, on the contrary, *diſſonancy*, he maintains to ariſe from diſproportionate motions of ſounds, not mixing, but jarring and claſhing as they paſs, and arriving in the ear grating and offenſive."

This notion of a conſonance exactly quadrates with that we have already laid down for a *concord*. Accordingly, moſt authors confound the two together; though ſome of the more accurate diſtinguiſh them; making conſonance to be what the word implies, a mere *ſounding of two or more notes together*, or *in the ſame time*; in contradiſtinction to the motion of thoſe ſounds *in ſucceſſion*, or one after the other.

In effect, the two notions coincide; for two notes, thus played in conſonance, conſtitute a concord; and two notes that pleaſe the ear in conſonance, will likewiſe pleaſe it in ſucceſſion. Notes in conſonance conſtitute harmony, as notes in ſucceſſion conſtitute *melody*.

In the popular ſenſe, conſonances are either *ſimple* or *compound*, &c. The moſt perfect conſonance is uniſon; though many, both among the ancients and moderns, diſcard it from the number of conſonances; as conceiving conſonance an agreeable mixture of different ſounds, grave and acute; not a repetition of the ſame ſound.

The ſecond conſonance is the octave; then the fifth, the fourth, the thirds, and the ſixths: the reſt are multiples, or repetitions of theſe.

Conſonance is ſometimes uſed by writers in the ſame ſenſe with concord, and thus, ſuch are ſaid to be variable, and the term imperfect is prefixed when applied to intervals which have a major and a minor of *the ſame name*, as thirds and ſixth, and perfect when applied to concords which never change their name, as the fifth, fourth, and octave; the abſurdity of this uſe of the words perfect and imperfect is ſo apparent, that we wiſh to ſee them diſuſed, and diſcountenanced in elementary books on muſic, in order that theſe terms may excluſively apply to intervals correctly tuned or perfect in reſpect of their accordance, or the reverſe: there was an impropriety in originally aſſigning one name to the thirds and to the ſixth, which naturally have no nearer relation to each other, than the fourth and fifth, or octave and uniſon, or even ſo much; but theſe being eſtabliſhed in uſe, may ſafely remain, without our continuing to confound and reverſe all ideas of perfection and imperfection, in conſequence only of this defect in the muſical nomenclature.

Conſonances are ſaid, by Dr. Smith, (Harmonics, p. 19.) to be *pure,* where none of the equal times between the pulſes of the acuter ſound are ſubdivided by any intermediate pulſe of the graver; and *interrupted* when any of thoſe equal times are interrupted by one or more pulſes of the graver ſound. See Cycle.

CONSONANT, in *Grammar*, a letter which cannot be perfectly ſounded by itſelf; but joined with a vowel, forms an articulate ſound, by a particular motion or contact of the parts of the mouth: and hence the name *con-ſonant,* q. d. *quæ ſonant cum alia.*

A conſonant, conſidering it philoſophically, is nothing elſe but the modification of a ſound, produced by means of the organs of the voice, not a production of ſound itſelf: thus, v. gr. the ſounds ſignified by the characters, *a, e, i, o, u,* &c. are differently modified when we ſay *ab*, than when we ſay *ac* or *ca, ad* or *da*; and thoſe modifications are called *conſonants.*

Accordingly, Dr. Wilkins (Eſſay towards a real Character, p. 366.) defines conſonants to be thoſe letters, in the pronouncing of which the breath is intercepted, by ſome colliſion or cloſure, among the inſtruments of ſpeech: and for this reaſon, he ſays, they are ſtyled "*clauſæ literæ,*" in contradiſtinction to vowels, which are "*apertæ.*" See Vowel.

Conſonants are divided into *ſingle,* as *b, m, q,* &c. and *double,* as *x* in *axillary,* correſponding to the *ξ* of the Greeks.

Conſonants have been alſo divided into *mutes* and *ſemi-vowels.* The mutes are ſuch as cannot be ſounded *at all* without a vowel, and all of which begin their ſound with a conſonant; as *b, d, g, k, p, q, t,* and *c* hard, being expreſſed *be, de, te,* &c. The ſemi-vowels have of themſelves an imperfect ſound, and all begin with a vowel; as *l, m, n, r, f, s,* &c, being ſounded *ef, el, em,* &c. Four of theſe, viz. *l, m, n, r,* are diſtinguiſhed by the name of *liquids,* from their readily uniting with other conſonants, and flowing, as it were, into their ſounds. The mutes, as ſome writers have deſcribed them, are thoſe conſonants whoſe ſounds cannot be protracted; and the ſemi-vowels are thoſe whoſe ſounds can be continued at pleaſure, partaking of the nature of vowels, from which they derive their name. The mutes may again be ſubdivided into *pure,* being thoſe whoſe ſounds cannot be at all prolonged, as *k, p, t*; and *impure,* whoſe ſounds may be continued for a ſhort time, as *b, d, g.* The ſemi-vowels may be ſubdivided into *vocal* and *aſpirated:* the former being formed by the voice, and the latter by the breath. The vocal, which are eleven, are *l, m, n, r, v, w, y, z, th* flat, *zh, ng*; and the aſpirated, five in number, are *f, h, ſ, th* ſharp, *ſh.* The vocal ſemi-vowels may be ſubdivided into *pure,* which are formed entirely by the voice, and *impure,* which are ſuch as have a mixture of breath with the voice. Of the pure there are ſeven, viz. *l, m, n, r, w, y, ng*; and four of the impure, viz. *v, z, th* flat, *zh.* The popular writer, whoſe "Grammar" we are now citing, has given the following liſt, exhibiting the ſounds of the conſonants, which are twenty-two in number.

b	*as heard in*	bay, tub.
d	——	day, ſad.
f	——	off, for.
v	——	van, love.
g	——	egg, go.
h	——	hot.
k	——	kill, oak.
l	——	lap, all.
m	——	my, mum.
n	——	no, on.
p	——	pit, map.
r	——	rat, far.
ſ	——	ſo, leſs.
z	——	zed, buzz.
t	——	to, mat.
w	——	wo.
y	——	ye.
ng	——	ing.
ſh	——	ſhy, aſh.
th	——	thin.
th	——	then.
zh	——	viſion.

Mr. Murray adds, that ſeveral letters marked in the Engliſh alphabet, as conſonants, are either ſuperfluous, or repreſent, not ſimple, but complex ſounds. C, *e. g.* is ſuperfluous in both its ſounds; the one being expreſſed by *k,* and the other by *ſ.* G, in the ſoft pronunciation, is not a ſimple but a complex ſound; as *age* is pronounced *adge.* *J* is unneceſſary, becauſe its ſound, and that of the ſoft *g,* are in our language the ſame. Q, with its attendant *u,* is either complex, and reſolvable into *kw,* as in *quality*; or unneceſſary, becauſe its ſound is the ſame with *k,* as in *opaque.* X is compounded of *gs,* as in *example,* or of *ks,* as in *expect.* See Murray's Engliſh Grammar, p. 4, &c. ed. 8.

Dr. Wilkins (ubi ſupra) diſapproves of the common diviſion of conſonants into *ſemi-vowels* and *mutes*; and prefers the diſtribution of them into three kinds, *viz.* ſpiritous or breathed, ſemi-ſpiritous or half-breathed, and non-ſpiritous or breathleſs. By the former he means ſuch conſonants as require to the framing of them a more ſtrong emiſſion of the breath, either through the noſe or mouth; and he diſtinguiſhes thoſe that are formed by expiration through the noſe into ſonorous, as *m, n, ng,* and mute, as *hm, hn,* and *hng:* the ſonorous being ſuch as require ſome vocal ſound for framing them, and the mutes being other letters of the ſame configuration, pronounced by a ſtrong emiſſion of the breath, without any vocal ſound. The ſpiritous conſonants that are formed by breathing through the mouth are alſo of two kinds, *viz.* ſonorous, as *v, dh, l, r, z, zh*; and mute, as *f, th, hl, hr, ſ,* and *ſh.*

Semi-ſpiritous or half-breathed conſonants are ſuch as are accompanied with ſome kind of vocal murmur, as *b, d, g*; whereas thoſe are denominated non-ſpiritous or breathleſs which are wholly mute, as *p, t, c.* Thus, *b* and *p* are framed when the breath is intercepted by the cloſure of the lips; the firſt of them being more ſoft, with ſome kind of murmur; the other more hard, and wholly mute. Again, *d* and *t* are commonly framed by an appulſe or colliſion of the top of the tongue againſt the teeth or upper gums; the firſt being more ſoft and gentle, with ſome kind of murmur; the other wholly mute. Moreover, *g* and *c* are framed more inwardly, by an interception of the breath towards the throat by the middle or root of the tongue, with ſuch a kind of difference between them as ſubſiſts in the two former caſes. The conſonants already enumerated belong to the claſs of thoſe that are ſimple; but thoſe that are called compound are uſually diſtinguiſhed into ſuch as are aſpirated, and ſuch as are double: the former ſeem to be blended with *h*, and are uſually ſo written; and the latter are compounded of ſome of the other letters, but for the ſake of diſpatch and brevity in writing, they are in ſeveral languages expreſſed by ſingle characters, and reckoned in the alphabet as if they were diſtinct ſpecies of ſimple letters: ſuch in the Latin alphabet are *q* and *x*, and the double letter *z*, whoſe power is the ſame as *ds* or *ts*. The conſonant *q* is allowed to be a compound of *c* and *u*; but what is the true original of *j* conſonant, and that power attributed to *ch* in the words *charity*, *cheeſe*, &c. have not been ſo well aſcertained. It is plain that neither of them is a ſingle letter, becauſe in the prolation of them we do not end with the ſame ſound with which we began: it ſeems, however, to be plain that *j* conſonant is a compound of *d* and *zh*, and *ch* of *t* and *ſh*. As for the other three conſonants that are reckoned in the common alphabet, *k*, *w*, *y*, Dr. Wilkins thinks them unneceſſary. If *c*, he ſays, be uſed always according to its proper power, *k* muſt be ſuperfluous; and therefore the Welſh, who uſe *c* for only one kind of ſound, have no *k*. And as for the letters *w* and *y*, their power is the ſame with that of the vowels ȣ and ι, as will evidently appear when they are rapidly pronounced before any other vowel by way of diphthong, ſo as to make but one ſyllable, ȣar or war, ſȣim or ſwim, ιes or yes, ιoke or yoke. Upon the whole, Dr. Wilkins enumerates 34 ſimple letters, 8 of which are vowels, and 26 conſonants, beſides 24 diphthongs. See LETTER.

According to ſome writers, the moſt natural diviſion of conſonants is that of the Hebrew grammarians; who have been imitated in this reſpect by the grammarians of other oriental languages: theſe divide the conſonants into five claſſes, with regard to the five principal orders of the voice; which all contribute, it is true, but one more notably than the reſt, to certain modifications, which make five general kinds of conſonants. Each kind, or claſs, comprehends ſeveral conſonants, which reſult from the different degrees of the ſame modification, or from the different motions of the ſame organs.

Theſe organs are the *throat*, *palate*, *tongue*, *teeth*, and *lips*; whence the five claſſes of conſonants are denominated *guttural*, *palatal*, *lingual*, *dental*, and *labial*.

We account ſixteen conſonants in the Engliſh alphabet, viz. *b*, *c*, *d*, *f*, *g*, *k*, *l*, *m*, *n*, *p*, *q*, *r*, *ſ*, *t*, *x*, *z*; to which there are three others to be added, viz. the *h*, and *j* conſonants, and *v* conſonant, which make the whole number of conſonants nineteen: one whereof is guttural, viz. the aſpirate *h*; five palatal, viz. *c*, as when pronounced before *a*, *o*, and *u*, as in *cavern*, *corn*, *curioſity*; *g*, as in *Geneva*; *j* conſonant in *julep*; *k* in *kernel*; and *q* in *query*. To theſe ſome have added *w* and *y*, which are really conſonants when they begin a word or ſyllable; although in every other ſituation they are called vowels. That they are conſonants when uſed as initials ſeems to be evident, from their not admitting the article *an* before them, and from their following a vowel without any hiatus or difficulty of utterance; that in other ſituations they are vowels appears from their regularly taking the ſound of other vowels.

The four *lingual* conſonants are *d*, *l*, *n*, *t*; the four *dental* are *r*, *s*, *x*, *z*, the three laſt whereof are *hiſſers*; and five *labial*, *b*, *f*, *m*, *p*, and *v* conſonant.

With regard to which diviſion it may be obſerved, that though the *g* be modified in three different manners, as it comes before an *a*, an *o*, or an *u*; yet it is ſtill a conſonant of the palate; that the *j* conſonant differs in nothing but its figure from the *g* before *e* or *i*; that *k* has the ſame pronunciation with the *c*; that *x* comprehends the ſound of two letters in its ſound, viz. *c* or *k*, and *ſ* or another *c*, as in *Alexander*, and *Alexis*, which we pronounce as if wrote *Alecſander* and *Aleccis*, or *Alecſis*; and that the *c* before an *e* or *i*, is no conſonant of the palate, becauſe in that caſe it loſes its proper ſound, and aſſumes the hiſſing ſound of the *ſ*.

The abbot Dangeau thinks the nature of the diviſion of the Hebrew grammarians to be very reaſonable; but he does not acquieſce in the diſtribution they have made of them: to find a natural and juſt diviſion of the conſonants, he obſerves, no regard muſt be had to the characters that repreſent them; nor any thing be conſidered but their ſound, or the modification they give the ſound.

On this principle, the ſame author finds in the French five *labial* conſonants, *b*, *p*, *v*, *f*, and *m*; five *palatal* ones, *d*. *f*, *g*, *k*, *n*; four *hiſſers*, *ſ*, *z*, *j*, *ch*; two *liquids*, *l* and *r*; two that run into and mix with each other, as *ll*, and *gn*; which laſt, however, is peculiar to the French language; and the *h* aſpirate.

He adds, 1. That *m* and *n* are properly two naſal conſonants; the *m*, a *b* paſſed through the noſe, and the *n* a *d*, in like manner, pronounced through the noſe; and, in effect; people with a cold pronounce *barket* for *market*, *deed* for *need*, &c.

2. That among the conſonants, ſome are weak, others ſtrong; their difference conſiſting in this, that the former are preceded with a ſmall emiſſion of the voice, which ſoftens them, which the latter have not. The weak are *b*, *c*, *d*, *g*, *z*, *j*; the ſtrong, *p*, *f*, *t*, *k*, *ſ*, *ch*.

It may be here obſerved, that when we ſpeak of a perſon's talking *through the noſe*, it muſt be underſtood in a ſenſe quite different from what the words ſeems naturally to import: ſince the noſe in this caſe concurs leſs to the pronunciation than when we do not ſpeak through the noſe; in regard the air, not being able to make its way through the noſe, is returned into the mouth, where it forms a dull obtuſe ſound, called *naſal*.

From the whole we may conclude, that the exceſs of conſonants in one language above another only conſiſts in this, that there are more modifications of ſound received and eſtabliſhed in the one than in the other: for all men, having the ſame organs, may form the ſame modifications; ſo that it is entirely owing to cuſtom, nothing to nature, that the Engliſh have not the ϑ of the Greeks, the *ain* and *heth* of the Hebrews, the *ch* of the Germans, the *gn* of the French, the *gl* of the Italians, the *ll* of the Welſh, &c.

Alſo, that the Chineſe have no *r*, the Iroquois no labial conſonants, the Hurons have abundance of aſpirates, and the Arabs and Georgians abundance of double conſonants: which laſt is owing to this, that they make ſeveral organs concur ſtrongly and equally to the modification of a ſound; whereas, in the reſt, only one organ is moved very ſtrongly and ſenſibly, and the reſt weakly.

It is hence alſo viſible, that in all languages the aſpirates, or guttural letters, are real conſonants; ſince the throat modifies the ſound as much as the palate, tongue, or lips.

Laſtly, to find all the conſonants that may be formed in any language, there needs nothing but to obſerve all the modifications that the ſounds of ſpeech will admit of, by which we ſhall have all the conſonants practicable.

Dr. Hunter (Edinb. Tranſ. vol. ii.) in his inveſtigation of the manner in which conſonants are formed, diſtinguiſhes them in two different reſpects, viz. by the operation of the breath which is employed to make them audible. There are *five* poſitions, he ſays, by which the vocal ſound is to be articulated: the *firſt* is formed by the cloſe junction of the lips, ſo that no breath is ſuffered to tranſpire, and the juſt modification of this poſition is that called *oral*, when the paſſage of the breath or ſound by the noſe is ſtopped, and thus are formed the letters *p* and *b*; and the ſecond modification, termed the *naſal*, is formed by opening the communication, or exit, by the noſe, and ſuffering the ſound or breath to paſs that way; in which caſe the letter *m* is ſounded. The *ſecond* poſition is formed by the application of the under lip to the fore-teeth of the upper jaw, which do not form an abſolute interruption to the breath, but ſuffer it to paſs in an audible manner, by means of the reſtraint with which it is made to paſs: and then are produced the letters *f* and *v*. The *third* poſition is formed by a ſimilar application of the tongue to the fore-teeth, and a ſimilar expreſſion of the breath; theſe producing the two conſonants θ and *th*. The *fourth* poſition is formed by the application of the point or fore part of the tongue to the root of the ſame teeth, or fore part of the palate, which poſition may be variouſly modified; as by applying the tongue cloſely to the palate, ſo as to form an abſolute interruption of the breath, in a manner ſimilar to that of the firſt poſition, which may be called the *mute* modification, and which ſeems to form the conſonants *t* and *d*. 2. The tongue is not kept cloſely fixed to the palate, but ſuffers the breath to be expreſſed in an audible manner, ſimilar to thoſe of the ſecond and third poſitions: this may be termed the *ſibilating* modification, and is that by which are expreſſed *ſ* and *z*. 3. The paſſage of the breath between the point of the tongue and the palate is opened alternately in a quick and tremulous vibration: this may be denominated the *vibratory* modification, and ſerves to form the letter *r*. 4. The paſſage of the breath or ſound is not interrupted in any degree, but it is made to paſs in a very peculiar manner through the mouth; for this purpoſe the tongue is cloſely applied to the fore part of the palate, but it is retracted on each ſide ſo as to leave an open ſpace, and then a paſſage is preſerved for the breath, which goes under the tongue and out of the mouth: this may be termed the *liquid* modification, and ſerves to form the ſonorous letter *l*. 5. The lateral paſſages opened for the breath in the laſt modification are ſhut, and the ſound at the ſame time is ſuffered to eſcape by the naſal paſſage, as in the ſecond modification of the *firſt* poſition: this may be denominated the *naſal* modification, and produces the letter *n*. The *fifth* poſition is formed in all reſpects like the *fourth*, but only by a different part of the tongue and palate, and has the ſame number of modifications, which correſpond in their nature, and may be denominated in the ſame manner. Thus, the letters *k* and *g* are formed in the *mute* modification; *ſh* and *j* in the *ſibilating;* the guttural or Northumbrian *r* in the *vibratory;* the Spaniſh *ll*, or the French *l mouillée*, in the *liquid;* and the guttural *n* or the Engliſh *ng* in the *naſal* modification. Having thus explained the ſeveral poſitions of the organ, with their different modifications, Dr. Hutton proceeds to illuſtrate the formation of the conſonants, and articulations of voice, by the action of the breath and ſound. In all the poſitions of the articulating organ, he ſays, there is either employed the ſimple aſpiration of the breath, or a ſound produced in the wind-pipe, and modified in the articulating organ. Thus, in all the poſitions, and in ſeveral of their modifications, there are produced two diſtinct articulators, according either as ſound is emitted along with the articulation, or only the breath employed without any other ſound. Hence proceeds the diſtinction of mutes and conſonants among the articulators of voice.

But in each of theſe diſtinctions of mutes and conſonants, it is neceſſary to make a ſub-diſtinction, according as the articulator is either perfect or imperfect, whether as a mute or as a conſonant. Each of theſe, the author explains in the following manner: The perfect mute can only take place in thoſe poſitions in which the breath is abſolutely interrupted by the cloſe or impervious organ; which does not happen in the ſecond and third poſitions, and only in ſome of the modifications of the fourth and fifth. This mute articulator is formed, either by interrupting the vocal ſound with the cloſe poſition, in which caſe it is a final articulator; or by beginning to expreſs the vocal ſound in this cloſe poſition, when it forms, upon opening the paſſage, an initial articulator. Of this kind there are juſt three articulators, correſponding to the three poſitions in which the organ may be abſolutely cloſed, in relation to the exit of the breath: theſe are *p* in the *firſt* poſition, *t* in the *fourth*, and *k* in the *fifth* poſition. The imperfect mute is formed by emitting a guttural ſound, or that of the wind-pipe, in theſe three poſitions of the mute articulator. The ſound here is extremely limited; for it is neceſſarily reſtricted to that quantity of breath which may be expelled through the ſounding wind-pipe in compreſſing the air, or diſtending the cavity of the cloſe organ. Theſe ſhort ſounded articulators may therefore be termed imperfect mutes. The *b*, *d*, and *g*, are the three imperfect mutes, correſponding to the three abſolute mutes, *p*, *t*, and *k*, of the *firſt*, *fourth* and *fifth* poſitions. In the ſibilating articulators of the *ſecond* and *third* poſitions, and of the ſecond modification of the *fourth* and *fifth* poſitions, the breath may be continually emitted, either with the ſimple expiration, or attended with the guttural ſound. This, then, forms two caſes of articulation, differing from each other, and alſo from the other two caſes of mute articulation; ſeeing that in the preſent caſe, whether the conſonant be formed with a guttural ſound, or only an audible aſpiration, it is a continued thing, and is not neceſſarily terminated, as in the mutes, by the cloſe poſition of the organ. Now, as in the caſe of mutes, we have the diſtinction of perfect and imperfect, with regard to that ſpecies of letter, ſo, in the caſe of conſonants, we have a ſpecies which is perfect, and one which is imperfect. The imperfect ſpecies of conſonant-articulators is formed in the four ſibilating poſitions and modifications juſt now mentioned, *viz.* the *f* in the *ſecond* poſition, the θ in the *third* poſition, the *ſ* in the ſibilating modification of the *fourth*, and the *ſh* in that of the *fifth* poſition. To perfect thoſe four conſonants, we have merely to add the guttural ſound to the continued expiration, and we then produce of the *f* the *v*, of the θ the *th*, of the *ſ* the *z*, and of the *ſh* the *j*. We have now only remaining the *naſal* modification of the *firſt* poſition, which gives the conſonant *m;* the *vibratory* modification of the *fourth* and *fifth* poſitions, which give two ſpecies of the letter *r;* the *liquid* modifications, which give two ſpecies of the letter *l;* and the *naſal* modifications of thoſe two laſt poſitions, which give two ſpecies of the letter *n*. In none of all theſe is formed a diſtinct articulator, by means of the ſimple aſpiration; conſequently all theſe are perfect conſonants. Our author obſerves, that the letter *h* is a general articulator, which is formed in many different poſitions of the vocal organ. Diphthongs and conſonant-vowels, or rather articulating vowels, are formed in the following manner: the diphthong, by ſounding both vowels equally in the time of one; the conſonant-vowel again, by an unequal diviſion of this time, or by ſliding quickly from the poſition of the two extreme vowels *i* and *u*, to the vocal ſound which is to be thus articulated. See Vowel.

Consonant, is a term in *Muſic*, which Dr. Callcott in his Muſical Grammar applies to the concords, octave, fifth, fourth, thirds major and minor, and ſixths major and minor. The conſonant triads, or common chords, according to the ſame author are,

in the major mode , and in the minor mode . See Triad.

CONSORT, *Queen*. See Queen.

CONSOUND, in *Botany*. See Symphytum and Solidago.

CONSOW, in *Geography*, a town of Poland, in the palatinate of Sandomirz; 28 miles S.E. of Radom.

CONSPIRACY, in *Law*, is taken for a combination or confederacy to do ſomething evil, or illegal: though in the original ſenſe of the word, and in its uſe in other languages, it ſignifies merely an agreement, whether for good, bad, or matters indifferent.

In our ſtatutes and law books, *conſpiracy*, in a general ſenſe, is frequently confounded with *maintenance*. and *champarty*.

Conspiracy, in its ſpecial ſignification, is uſed for a confederacy of two, at leaſt, falſely to indict one, or procure him to be indicted of felony; who, after acquittal, ſhall have writ of conſpiracy. See 33 Edw. I. ſtat. 2. 7 Hen. V. 18 Hen. VI. c. 12. The term is now commonly uſed for the unlawful combination of journeymen to raiſe their wages, or to refuſe working, except on certain ſtipulated conditions; an offence particularly provided for by ſtat. 2 & 3 Ed. VI. c. 15. reviſed, continued, and confirmed by ſtat. 22 & 23 Car. II. c. 19 (now expired); which enacts, among other things, that "if any artificers do conſpire, that they ſhall not do their work but at a certain price, or ſhall not take upon them to finiſh what another hath begun, or ſhall do but a certain work in a day, or ſhall not work but at certain times, every perſon ſo conſpiring ſhall forfeit for the firſt offence, 10*l.* or be impriſoned 20 days; for the ſecond, 20*l.* or be pilloried; and for the third, 40*l.* or be pilloried, loſe an ear, and become infamous." This ſtatute appears to be yet in force, though it be not frequently reſorted to for remedy in this caſe; the proceeding being uſually by indictment for conſpiracy.

By the common law all conſpirators wrongfully to prejudice a third perſon are highly criminal. 1 Hawk. P. C. c. 72. § 2. ſtat. 5 Eliz. c. 4. Journeymen confederating and refuſing to work unleſs for certain wages, may be indicted for a conſpiracy, although the ſtatutes which regulate their work and wages do not direct this mode of proſecution; for the offence conſiſts in the conſpiring, and not in the refuſal: and all conſpiracies are illegal, though the ſubject-matter of them may be lawful. Thus alſo, a bare conſpiracy to do a lawful act to an unlawful end is a crime, though no act be done in conſequence of it. 8 Mod. 321. The fact of conſpiring need not be proved on the trial, but may be collected by the jury from collateral circumſtances. 1 Black. Rep. 392. Stra. 144. And if the parties concur in doing the act, although they were not previouſly acquainted with each other, it is conſpiracy. 1 Hawk. P. C. c. 72. § 2. Writ of conſpiracy lies for him that is indicted of a treſpaſs, and acquitted, though it was not felony; alſo upon an indictment for a riot. 2 Mod. 306. 5 Mod. 405. Writ of conſpiracy lies where a man is falſely indicted of any crime which may prejudice his fame or reputation; and though it doth not import ſlander, if it endanger his liberty, or the indictment be injurious to his property, &c. 3 Salk. 97.

But though a conſpiracy to charge falſely be indictable, yet the party ought to ſhew himſelf to be innocent; for the writ of conſpiracy doth not lie without an acquittal. Mod. Caſ. 127. 185, 186. Not only writ of conſpiracy, which is a civil action at the ſuit of the party, but alſo action on the caſe in the nature of a writ of conſpiracy, doth lie for a falſe and malicious accuſation of any crime, whether capital or not capital, even of high treaſon; and this, though the bill of indictment be found *ignoramus*, or it does not go ſo far as an indictment. And the ſame damages may be recovered in ſuch action as in a writ of conſpiracy, where the party is lawfully acquitted by verdict. 1 Rol. Abr. 111, 112. 9 Rep. 56. Gilb. Ca. 185. 10 Mod. 148. 214. Salk. 15. An action on the caſe is preferable, as it is more in uſe, and the proceedings more eaſy and not attended with ſuch niceties as the writ of conſpiracy.

If one falſely and maliciouſly procure another to be arreſted, and brought before a juſtice of peace to be examined concerning a felony, &c. on purpoſe to vex and diſgrace him, and put him to charges and trouble, although he is not indicted for the ſame, yet he may have an "action on the caſe;" in which he need not aver that he was lawfully acquitted, as he ought to do in a writ of conſpiracy; but he muſt aver that the accuſation was *falſé et malitioſé*, which words are neceſſary in the declaration; and it muſt appear that there was no ground for it. And as an "action on the caſe" may be proſecuted againſt one perſon, where the writ of conſpiracy or indictment doth not lie but againſt two, this action is moſt commonly brought. 1 Danv. Abr. 208. 213. 2 Inſt. 562. 638.

Conſpirators may be indicted at the ſuit of the king, and at the common law, one may prefer an indictment againſt conſpirators, though nothing be executed: however, the conſpiracy ought to be declared by ſome act, or promiſe to ſtand by one another, &c. But a bare conſpiracy will not maintain a writ of conſpiracy, at the ſuit of the party, becauſe he is not damaged by it; though it is a ground for an indictment. 9 Rep. 56. 2 Roll. Abr. 77. If the defendants can ſhew any foundation or probable cauſe of ſuſpicion, they ſhall be diſcharged: and if a man hath good cauſe of ſuſpicion, that a perſon is guilty of felony, and cauſes him to be indicted, in proſecution of juſtice, action of conſpiracy will not lie; but it is otherwiſe if the proſecutor impoſes the crime of felony, where no crime of felony was committed. 1 Roll. Abr. 115. 4 Rep. 438. Conſpiracies ought to be out of court; for if a proſection be ordered in a courſe of juſtice, and witneſſes appear againſt a party, &c. there ſhall be no puniſhment; and if perſons acted only as jurors in a criminal matter, or judges in open court, there is no ground for proſecution. S. P. c. 173. 12 Rep. 24. If all the defendants but one are acquitted on indictment for conſpiracy, this one muſt be alſo acquitted; becauſe one perſon alone cannot be indicted for this crime: and huſband and wife, being but one perſon, may not be indicted alone for a conſpiracy. 2 Rol. Abr. 708. The acquittal of one perſon is the acquittal of another upon indictment of conſpiracy (3 Mod. 220.) *i. e.* where only two are indicted, and it is not laid or proved that they conſpired with others, unknown. However, where one is found guilty, according to the opinion of lord chief juſtice Hale, if the other doth not come in upon proceſs, or if he dies pending the ſuit, judgment ſhall be had againſt the other. 1 Vent. 234. It hath been reſolved, that if an "action on the caſe" be brought againſt ſeveral perſons, and all but one be acquitted, yet judgment may be given againſt that one only. 1 Hawk. 192. Judgment may be alſo given againſt one only before the trial of the others: and it has been held, that a conſpiracy may be laid without any overt act. 1 Str. 193. Perſons acting ſeparately may be alſo guilty of a conſpiracy; as particularly in the caſe where they are all of a family, *e. g.* huſband, wife, and ſervants. 1 Str. 144.

If the parties are found guilty of conſpiracy, upon an indictment of felony, at the king's ſuit, the judgment anciently was, that they ſhould loſe their "frank-law," (which diſabled them to be put upon any jury, to be ſworn as witneſſes, or to appear in perſon in any of the king's courts,) and that their lands, goods, and chattels ſhould be forfeited into the king's hands, their houſes and lands ſtripped and waſted, their trees rooted up, and their bodies impriſoned. This is commonly called "villainous" judgment, and is given by the common law, and not by any ſtatute, and in ſome books it is ſaid generally to be the proper judgment upon every conviction of conſpiracy at the ſuit of the king, without any reſtriction to ſuch as endangered the life of the party; but this point doth not ſeem to be any where ſettled. 1 Hawk. 193. 2 Inſt. 143. 222. This judgment, however, hath been but ſeldom given; there being no inſtance of it ſince the reign of Edw. III. The uſual mode of puniſhment at preſent is by pillory, fine, impriſonment, and ſurety for good behaviour. Burr. 996. 1027. Str. 196. The quarter ſeſſions have juriſdiction over this offence. Finch. 80. 8 Mod. 321. And on motion in arreſt of judgment, the defendant muſt be perſonally preſent in court. Stra. 1227. Burr. 931.

In caſes where villainous judgment is impoſed, the matter of the conſpiracy ought to touch a man's life. As fine and impriſonment are at this day the uſual puniſhment for conſpiracy, ſo on writ of conſpiracy, &c. the party ſhall be fined, and render damages. 1 Hawk. P. C. 72.

CONSPIRATION, Fr. See Conspiracy.

Conspiration, *contre le ſervice du Roi*, conſpiracy againſt the king's ſervice. Under the old government of France every conſpiracy, colluſive, or unlawful combination or underſtanding againſt the king, his governors, commanders, or other officers, was regarded as a capital military offence; and by an order of the 1ſt July 1727, it was enacted that every perſon convicted of ſuch a crime ſhould be broken on the wheel.

CONSPIRATIONE, in *Law*, a writ that lies againſt *conſpirators*. Reg. Orig. 134. F. N. B. 114.

CONSPIRATORS, according to the ſtatute, are thoſe that do confederate, or bind themſelves by oath, covenant, or other alliance, that every one of them ſhall aid, and bear the other, falſely and maliciouſly, to indict, or cauſe to indict, or falſely to move, or maintain pleas: and ſuch as retain men in the country, with liveries or fees, to maintain their malicious enterprizes: and this extendeth as well to the takers, as the givers: and ſtewards, and bailiffs, of great lords, which, by their office, or power, undertake to bear, or maintain quarrels, pleas, or debates, that concern other parties than ſuch as touch the eſtate of their lords, or themſelves. 33 Edw. I. ſtat. 2. 2 Inſt. fol. 384. 562.

Moreover, againſt conſpirators, falſe informers and embracers of inqueſt, the king hath provided a writ in the chancery; and the juſtices of either bench and juſtices of aſſize, ſhall, on every plaint, award inqueſt thereupon. Stat. 28 Ed. I. ſt. 3. c. 10. There are alſo conſpirators in treaſon, by plotting againſt the government, &c. See Treason.

CONSPIRING Powers, in *Mechanics*, are all ſuch as act in directions not oppoſite to one another. See Power, and Motion.

CONSTABLE. This appellation hath afforded ample matter of diſquiſition to learned antiquarians. Hiſtory has traced it backwards from its introduction to England, through France, Germany, and Greece, to the imperial ſeat at Conſtantinople, in the days of Conſtantine the Great; and if we aſcend farther towards the Eaſt, we ſhall find the term *cône* or *cûne* in Paleſtine, which ſignified in the times of the Old Teſtament, a ſtability, ſtrength, or ſtay. Some trace of this word has been diſcoverable in the appellation of Laocoon at Troy, and particularly in that of Conſtantine, who was himſelf of oriental extraction, having ſprung from Dardania, a country of Upper Mœſia, and ſaid by flatterers to have been deſcended from Dardanus and the Trojans. It is not improbable that this appellation of the emperor might have occaſioned the adoption of the word into the Roman language about the ſame time. For it was at that period that the word *count*, obviouſly deduced from *cone* or *cune*, firſt became a name of dignity; and from thence was tranſmitted weſtwards, with ſome variation, according to the different genius of languages throughout the provinces. Amongſt the Saxons the word was *koning* or *kyninge*, from which, without doubt, we derive our word king. Moreover, the word *ſtole*, *ſtolle*, *ſtaſle*, or *ſtable*, by an eaſy tranſmutation of the ſeveral letters frequent in almoſt all languages, which ſeems to be the other conſtituent of the appellation *conſtable*, is likewiſe common to the languages of the middle ages, and ſignifies a ſtanding place, diviſion, or department, called by the Romans *ſtatio*. According to this etymology, the word *conſtable* ſignifies the ſtability or ſtay of the place, or the ſtrong man of the diviſion. Thoſe who derive it from the Saxon, diſcover conſtable in *koningſtapel*, denoting the ſupport of the king. But others, as ſir Henry Spelman, and Dr. Cowel, conſidering that we borrow the name, as well as the office, from the French, deduce it, with greater probability, from that language; in which it is plainly derived from *comes ſtabuli*, the maſter of the ſtables, or perhaps of the horſe, an officer well known in the empire; ſo called, becauſe, like the great conſtable of France, as well as the lord high conſtable of England, he was to regulate all matters of chivalry, tilts, tournaments, and feats of arms, which were performed on horſeback. Accordingly, they ſuppoſe, that the dignity, which at firſt was civil, in time became military, and the maſter of the ſtables was made general of the army.

Constable *of England, Lord High,* is an ancient officer of the crown, now diſuſed in England, except on ſolemn occaſions, as the king's coronation, and the like. The firſt conſtable of England is ſaid to have been created by the conqueror, who appointed Ralph de Mortimer, one of the principal commanders of his army; and the office continued till the reign of Henry VIII., A. D. 1521; when it became extinct, as the powers annexed to it rendered it troubleſome to the king, by the attainder of the third duke of Buckingham, who derived it from the Bohuns, earls of Hereford, and in whom it was hereditary. Since this time there hath not been any permanent high conſtable; but the office has been kept vacant, except on particular occaſions. About a century after, *viz.* in 1627, it was alſo ſuppreſſed in France, by an edict of Louis XIII.; though the office has been exerciſed in the command of the marſhals, by the firſt officer in the army. See CONNETABLE.

What authority and juriſdiction belonged to the conſtable, we may partly learn from a ſtatute of the 13th of Richard II., in which it is ſaid "that he ought to have cognizance of contracts touching feats of arms and of war out of the realm, and alſo of ſuch things relating to arms or war within the realm, as could not be determined or diſcuſſed by the common law, with other uſages and cuſtoms appertaining to the ſame matters, which other conſtables before that time had duly and reaſonably uſed." Madox (Hiſt. Excheq. c. 11.) ſays, that he was a high officer, both in war and peace. As the duties enjoined on the conſtable and mareſchal or marſhal, as well in war as in peace, in camp and in court, were multifarious, honourable, and confidential; ſo the powers, privileges, authority, and preeminence of thoſe officers, were extenſive, judicial, executory, and reſpectable. The powers and functions of each of theſe two high officers, when acting in their military capacities, were, in ſome inſtances, concurrent; in others, ſeparate and independent. In the diſcharge of ſome official duties, they were upon an equal footing, and the marſhal acted as coadjutor to the conſtable, but in others, the former was ſubordinate and ſubſervient to the latter. The functions of the conſtable, in his civil capacity, were few, and in a great meaſure reſtricted to certain perſonal attendances on the king in his court, on high feſtivals, and on occaſions when ſuch affairs were tranſacted as required pomp and ſolemnity. In his military capacity, the conſtable examined the number and qualifications of thoſe who were ſent by the military tenants, either into the field or garriſon, and alſo of the ſtipendiaries retained by the king, and gave them either their admittance or diſcharge. When the army took the field, and was commanded by the king in perſon, the conſtable acted as his lieutenant, and was next to him in authority; but whenever the king was abſent, the conſtable had the ſupreme and ſole command of the forces. In both caſes, the marſhal was the ſubſtitute or vice-general of the conſtable. See COURT *of Chivalry*, and MARSHAL.

From thoſe mighty magiſtrates, the conſtables of England, are derived the inferior ones, ſince called the *conſtables of hundreds and franchiſes:* theſe were firſt ordained in the thirteenth year of Edward I. by the ſtatute of Wincheſter (13 Ed. I. ſtat. 2. c. 6.); which, for the conſervation of the peace, and view of armour, and for preſenting defaults of armour, and of the ſuits of towns and of highways, &c. appointed, that two conſtables ſhould be choſen in every hundred and franchiſe.

Theſe are what we now call *conſtabularii capitales*, or *high conſtables;* becauſe continuance of time, and increaſe of people, &c. have occaſioned others of like nature, but inferior authority, in every town and pariſh, called *petty conſtables*, or *ſub-conſtabularii*, firſt inſtituted (as ſome ſay) about the reign of Edward III.

Although it has been a prevalent opinion, maintained by Coke, Hale, and others, that high conſtables are not more ancient than the ſtatute of Wincheſter above cited; yet Hawkins concurs with others in maintaining, that both conſtables of hundreds, commonly called high conſtables, and alſo conſtables of tythings, now denominated petty conſtables or tything-men, exiſted by the common law, and were not firſt ordained by the ſtatute of Winton or Wincheſter; for that ſtatute doth not ſay, that ſuch officers ſhall be conſtituted, but evidently ſeems to ſuppoſe that there were ſuch before the making of it. 2 Hawk. 61. That the high conſtable was inſtituted long before the ſtatute of Winton is a fact aſcertained by a writ or mandate of Henry III., preſerved in the Adverſaria to Watts's edition of Matt. Paris, and from which chapters 4 and 6 of the ſtatute of Winton are evidently taken. By this writ it is provided, "that in every hundred there ſhall be *conſtituted* a CHIEF CONSTABLE, at whoſe mandate all thoſe of his hundred, ſworn to arms, ſhould aſſemble and be obſervant to him, for the doing of thoſe things which belong to the conſervation of the king's peace." No mention of this officer, it is believed, can be any where found prior to the date of this inſtrument; which perhaps may no more determine the queſtion as to his original creation than the ſtatute of Winton. As for the "conſtable of the vill," or petty conſtable, as he is frequently called by way of diſtinction from the chief conſtable, this officer has been repeatedly acknowledged to be one of the moſt ancient officers in the realm, for the conſervation of the peace (Poph. 13. 4 Inſt. 265.). It muſt be confeſſed, however, that no mention of him by this identical name is any where found to occur anterior to the writ or mandate of king Henry III. already mentioned; by which it is alſo provided, that in every village or townſhip there ſhould be conſtituted a conſtable or two, according to the number of the inhabitants. But it is partly certain that lord Coke's idea is well founded, and that "this officer is actually owing to the inſtitution of the frank-pledge, uſually attributed to king Alfred," and was in fact originally the ſenior or chief pledge of the tything or *decima*. Hence it appears, that the ordinance of Henry III., far from inſtituting the office, merely enlarged the number of officers, placing them in towns and villages, inſtead of franchiſes; hence it might frequently happen, that a manor of great extent had only a ſingle conſtable for ſeveral townſhips; a caſe exactly ſimilar ſometimes occurring at this day, in which a townſhip, comprehending ſeveral hamlets, equally populous perhaps with itſelf, has only one conſtable for the whole. Upon the whole, it ſeems highly probable, that, at the common law, and before the mandate of Henry III., the conſtable of the hundred and the conſtable of the manor, were officers of the ſame nature and authority, originating at the ſame time and differing only as to the extent of their ſeveral diſtricts; in ſhort, that they bore to each other the ſame analogy as ſubſiſted between the bailiff of the hundred and the bailiff of the manor. Hence it follows, that the conſtable of the hundred neither poſſeſſed nor could have exerciſed any more authority within the precinct of the latter, than the conſtable of one manor poſſeſſed or could have exerciſed in another; the manor being to all intents and purpoſes exempt from, and excluded out of the hundred.

High conſtables are choſen at the court leets of the franchiſe or hundred over which they preſide, or, in default of that, by the juſtices at their quarter ſeſſions, or by the greater number of the juſtices of the diviſion: and they are ſworn at the ſeſſions, or by warrant from the ſeſſions; which courſe hath often been allowed and commended by the juſtices of aſſize. Dalt. c. 28. Salk. 150. And by ſtat. 29 Geo. II. c. 25, §8, 9, in Weſtminſter a high conſtable is to be elected annually by the dean or high ſteward or his deputy at a court leet. But by 1 Geo. ſtat. 2. c. 13. high conſtables are required to take the oaths of allegiance, ſupremacy, and abjuration, as other perſons who qualify for offices; but they are not within the ſtatute of the 25 C. II. c. 2. as to receiving the ſacrament and ſubſcribing the declaration againſt tranſubſtantiation; and petty conſtables are exempted both from the one and from the other. The petty conſtables have two offices united in them; the one ancient, the other modern. Their ancient office is that of *Head*-BOROUGH (which ſee), tything-man, or borſholder, who are as ancient as the time of Alfred; and their more modern office is that of conſtable merely, which was appointed (as it has been ſaid) ſo lately as the reign of Edward III., in order to aſſiſt the high conſtable. And, in general, the ancient head-boroughs, tything-men, and borſholders, were made uſe of to ſerve as petty conſtables; though not ſo generally, but that in many places they ſtill continue diſtinct officers from the conſtable.

The common law requires, that every conſtable ſhould be *idoneus homo*, i. e. apt and fit to execute the ſaid office; and in law he is ſaid to be *idoneus* when he poſſeſſes three qualifications, *viz.* honeſty, knowledge, and ability, (8 Rep. 41. *b.*) And if one be elected conſtable, who is not *idoneus*, he by the law may be diſcharged of his office, and another who is *idoneus* appointed in his place. He muſt alſo be an inhabitant of the place for which he is choſen, (12 Mod. 256.) nor ſhould he be the keeper of a public-houſe, (6 Mod. 42.) which is made an expreſs diſqualification in Weſtminſter, by ſtat. 29 Geo. II. c. 25. Perſons exempt from ſerving the office of conſtable are aged perſons, and in Weſtminſter thoſe 63 years old are expreſsly exempted by ſtat. 31 Geo. II. c. 17. § 13;—aldermen of London;—the preſident, commons and fellows of the college of phyſicians in London, by 32 Hen. VIII. c. 40; but no other phyſicians, nor they elſewhere:—apothecaries, practiſing in, or within ſeven miles of London, free of the company, or in the country having ſerved ſeven years, ſtat. 6 and 7 W. III. c. 4;—ſurgeons, free of the company of ſurgeons in London, examined, approved, and exerciſing the ſcience, by ſtats. 5 Hen. VIII. c. 6: 32 Hen. VIII. c. 42: 18 Geo. II. c. 15; and by cuſtom all ſurgeons (Com. Rep. 312.), and it ſeems by the ſame ſtats. barbers free of that company in London;—attornies of the courts of K. B. and C. P.;—practiſing barriſters;—diſſenters, being teachers and preachers in a congregation, tolerated by law, taking the oaths and making the required declaration, but not others, by 1 W. c. 18. § 11;—foreigners naturalized, who may rather be ſaid to be incapacitated;—militia-men, during the time of their ſervice, by 26 Geo. III. c. 107. § 130;—ſervants to members of parliament, but doubtful;—proſecutors of felons to conviction; the original proprietors, or firſt aſſignee of a certificate (commonly called a tyburn-ticket), if a pariſh or ward office; within the pariſh or ward where the felony happened; to be only once uſed, by 10 and 11 W. c. 23. § 23; but this is no exemption from ſerving the office for a manor, nor, as it ſhould ſeem, for a vill or townſhip; nor where the office is to be executed out of the privileged diſtrict;—but maſters of arts, juſtices of peace in another county, officers of the guards, officers or watchmen at the Cuſtom-houſe, tenants in ancient demeſne, and younger brothers of the trinity-houſe, cannot plead exemption. If, however, a gentleman of quality, or a phyſician, officer, &c. be choſen conſtable, where there are ſufficient perſons beſides, and no ſpecial cuſtom exiſts; ſuch perſons, it is ſaid, may be relieved in B. R. 2 Hawk. P. C. 100. c. 10. § 41. A conſtable, whoſe office is miniſterial, and not judicial, may appoint a deputy; but the conſtable is anſwerable, and his deputy ought to be ſworn, though this is not in all caſes neceſſary; but if the deputy is allowed and ſworn, the principal is not reſponſible. Diſſenters choſen to the office of conſtable, &c. ſcrupling to take the oaths, may execute the office by deputy, who ſhall comply with the law in this behalf, ſtat. 1 W. & M. c. 18. § 7. And by 31 Geo. III. c. 32. the like privileges are given to Roman Catholics on their taking and ſubſcribing the oath and declaration therein ſpecified. Conſtables may appoint a deputy to execute a warrant, when by reaſon of ſickneſs, &c. they cannot do it themſelves. A woman made conſtable, by virtue of a cuſtom, that the inhabitants of a town ſhall ſerve by turns, on account of their eſtates or houſes, may procure another to ſerve for her, and the cuſtom is good.

Conſtables are choſen by the common law at the leet, or, where there is no leet, at the tourn; ſometimes by the ſuitors, and ſometimes by the ſteward; and now, in many towns and pariſhes, by the pariſhioners: all according to ancient and particular uſage. But by whomſoever they ſhall be choſen and appointed, they are to be ſworn and placed in their office by the lord, or his ſteward, or by the ſheriff reſpectively, as being judge of the court. 2 Hawk. 62. If the conſtable be preſent when choſen, he is to take the oath in court; if abſent, he may be ſworn before a (ſingle) juſtice of the peace: but in the latter caſe, he ought to have ſpecial notice of his election, and a time and place ſhould be appointed for his taking the oath (well and truly to ſerve the office). Every petty conſtable being a principal peace officer, and it being neceſſary for the preſervation of the peace, that every vill ſhould be furniſhed with one, the juſtices of the peace have, ever ſince the inſtitution of their office, taken upon them, as conſervators of the peace, not only to ſwear the petty conſtables, who have been choſen at a tourn or leet, but alſo to nominate and ſwear thoſe who have not been choſen at any ſuch court, on the neglect of the ſheriffs or lords to hold their courts, or to take care that ſuch officers are appointed in them. And this power of juſtices of the peace, having been confirmed by the uninterrupted uſage of many ages, ſhall not now be diſputed, but ſhall be preſumed to have been grounded on ſufficient authority. Some have carried this point ſo far, as to allow the juſtices, at their ſeſſions, to ſwear one who was choſen at the leet, and unduly rejected by the ſteward, who had ſworn another in his place. 2 Hawk. 65. A conſtable has been ſworn by a ſingle juſtice of the peace; and upon motion for an information as not being duly ſworn, the court held this to be a good ſwearing. 2 Strad. 1149. It is certain that juſtices of the peace had power to nominate and ſwear conſtables, on the default of the tourn or leet, before the ſtatute of 13 & 14 C. II. c. 12.; and therefore that they have ſuch authority in ſome caſes not mentioned in that ſtatute, which enacts, that if a conſtable ſhall die, or go out of the pariſh, any two juſtices may make and ſwear a new one, until the lord ſhall hold a leet, or till the next quarter ſeſſions, who ſhall approve of the officer ſo made and ſworn, or appoint another; and if any officer ſhall continue above a year in his office, the juſtices in their quarter ſeſſions may diſcharge him, and put in another, till the lord ſhall hold a court as aforeſaid. 2 Hawk. 65. 13 & 14 C. II. c. 12. § 15. It ſeems to be clear at this day, that the King's Bench hath power by mandamus to compel the court or judge to ſwear a conſtable duly choſen. 2 Hawk. 65. And conſtables lawfully choſen, if they ſhall refuſe to be ſworn, may be bound over by a juſtice of the peace to the aſſizes or ſeſſions, there to be indicted. Dalt. c. 28. 2 Str. 920. But it ſeems that a juſtice hath no power to commit any perſon for ſuch refuſal and no more, the proper mode being to indict him upon his refuſal; and if found againſt him, to aſſeſs a good fine upon him. Cro. Car. 567.

Conſtables of London, which city is divided into 26 wards, and every ward into precincts, in each of which is a conſtable, are nominated by the inhabitants of each precinct on St. Thomas's day, and confirmed, or otherwiſe, at the court of wardmote; and after they are confirmed, they are ſworn into their office, at a court of aldermen, on the next Monday after Twelfth-day. The oath of theſe conſtables is long and particular, and comprehends a variety of duties, now ſeldom performed, but regulated by articles of the Wardmote inqueſt, which directs the conduct of the conſtable; who is a kind of ſuperintendant of the morals of the inhabitants, and who ought to notice all new-comers, that thoſe whoſe character is bad may be required to give ſecurity for their good behaviour, or be impriſoned. Carth. 129. 138. Every conſtable may execute warrants through the whole city. Such as are choſen into the office are obliged to place the king's arms, and the arms of the city, over their doors; and if they reſide in alleys, at the ends of ſuch alleys, towards the ſtreets, to ſignify that a conſtable lives there, and that they may be more eaſily found when wanted.

The general duty of all conſtables, both high and petty, is to keep the king's peace in their ſeveral diſtricts; and for this purpoſe they are armed with very large powers, of arreſting, and impriſoning, and of breaking open houſes, and the like. One of their principal duties, ariſing from the ſtatute of Wincheſter, which appoints them, is to keep watch and ward in their reſpective juriſdictions. See WARD and WATCH.

If any one ſhall make an affray or aſſault upon another, in the preſence of the conſtable, or ſhall threaten to kill, beat, or hurt another, or in a fury be ready to break the peace; the conſtable may commit him to the ſtocks, or other ſafe cuſtody, and afterwards take him before a juſtice, or to a gaol, until he ſhall find ſurety for the peace; and if the party will not find ſurety to the conſtable, he may impriſon the party till he ſhall do it, provided the offence be in his own view. Dalt. c. 1. Cro. Eliz. 375, 376. The duties of conſtables are ſo numerous and minute, in conſequence of a variety of ſtatutes, that the mere recital of them would extend this article beyond its due bounds. They will be found under ſeveral different heads or titles, that occur in this work.

If a conſtable neglect any duty incumbent on him either by common law or by ſtatute, he may be indicted and fined by the juſtices of peace, to whom he is ſubordinate. If he will not return his warrant, or certify what he has done under it, he may be fined. If he wilfully lets a felon eſcape out of the ſtocks, and go at large, it is felony; and it ſeems generally agreed, that all voluntary eſcapes in the officer amount to the ſame crime as the offender was guilty of, whether treaſon or felony. 2 Hawk. P. C. c. 19. § 22, &c. It is a miſdemeanour in him to diſcharge an offender, brought to the watch-houſe by a watchman in the night. In ſhort, he is liable to various pecuniary, and ſometimes perſonal, puniſhments, on neglecting the duty impoſed on him by various ſtatutes. As by his office he is ſubordinate to a juſtice of the peace, he is bound to execute his warrants; and therefore it hath been reſolved, that where a ſtatute authoriſes a juſtice of the peace to convict a man of a crime, and to levy the penalty by warrant of diſtreſs, without ſaying to whom ſuch warrant ſhall be directed, or by whom it ſhall be executed, the conſtable is the proper officer to ſerve ſuch warrant, and indictable for diſobeying it. 2 Hawk. 262. By 33 Geo. III. c. 55. two juſtices, at any ſpecial or petty ſeſſions, upon complaint upon oath, of any neglect of duty, or diſobedience of any lawful warrant or order of any juſtice, by any conſtable, or other peace or pariſh officer, (ſuch perſon being duly ſummoned to appear and anſwer to ſuch charge,) may impoſe, upon conviction, any reaſonable fine, not exceeding 40*s*., upon ſuch conſtable, &c.; and if not paid, levy the ſame by diſtreſs and ſale of the goods of ſuch offender, to be applied to the poor of the pariſh or place where he reſides; or for want of ſuch diſtreſs, the offender ſhall be committed to the houſe of correction for any time not exceeding ten days. The officer executing ſuch warrant, if required, ſhall ſhew the ſame to the perſon, whoſe goods and chattels are diſtrained, and ſuffer a copy of it to be taken. 27 Geo. III. c. 26.

On the other hand, the conſtable is protected by law, in the execution of his duty. By ſtat. 7 Jac. I. c. 5. 21 Jac. II. c. 12. if any action is brought againſt a conſtable for any thing done by virtue of his office, he, and all who aid him, may plead the *general iſſue,* give the ſpecial matter in evidence, and if he recovers, ſhall have double coſts; but this muſt be certified on the record by the judge: and ſtat. 19 Geo. II. c. 21. againſt profane ſwearing, gives treble coſts. By ſtat. 24 Geo. II. c. 44. no action ſhall be brought againſt any conſtable or others aſſiſting him for any thing done in obedience to any warrant of a juſtice of peace, until demand of the peruſal and copy of ſuch warrant, and the ſame hath been refuſed or neglected for the ſpace of ſix days, &c. &c. No action ſhall be brought againſt any conſtable but within ſix months after the act committed. For the charges of conveying malefactors to gaol, ſee COMMITMENT. By 27 Geo. II. c. 20. the conſtable executing a juſtice's warrant, for levying a penalty or other ſum of money directed by an act of parliament by diſtreſs, may deduct his own reaſonable charges; and if any perſon ſhall be appointed to execute any warrant for felony, two juſtices may order by warrant under their hands a reaſonable allowance to ſuch ſpecial conſtable for his expences and loſs of time, to be paid by the treaſurer out of the county rate. 41 Geo. III. c. 78. Two juſtices may in like manner order an allowance to be made to any high conſtable for exttaordinary expences incurred in the execution of his office, to be defrayed in the ſame manner. And by 18 Geo. III. c. 19. every conſtable, headborough, and tything-man, ſhall every three months, and within fourteen days after he goes out of office, deliver to the overſeers of the poor a written account, entered into a book kept for that purpoſe, and ſigned by him, of all ſums expended in conſequence of his office, which the overſeers within the next fourteen days ſhall lay before the inhabitants, and if approved, the money ſhall be paid out of the poor rate: but if diſallowed, they are to return the book to the conſtable, who may produce it before a juſtice of peace, giving reaſonable notice to the overſeers; and the juſtice ſhall examine the account, ſettle the ſum due, ſign the account, and order payment out of the poor rate; the overſeers, however, may appeal to the quarter ſeſſions.

If a onſtable commits a perſon in charge, he is not liable to an action for falſe impriſonment, though the charge be ill-founded; and if the conſtable is aſſaulted in the execution of his office, and the conſtable kill the aſſailant in a conteſt, it is no felony; but if the conſtable is killed, it ſhall be conſtrued premeditated murder. A juſtice of peace's warrant is a ſufficient juſtification of a conſtable in a matter within the juriſdiction of ſuch juſtice.

High conſtables ſhall account, if required, at the general or quarter ſeſſions, for the general county-rate by them received, on pain of being committed to gaol until they account; and they ſhall pay the money in their hands, according to the order of the court, under the like penalty. 12 Geo. II. c. 29.

Conſtables may be removed in the ſame manner and by the ſame authority by which they were choſen. The ſheriff, or ſteward of the leet, having power to place a conſtable in his office, has alſo a power of removing him. Juſtices of the peace have alſo diplaced ſuch conſtables as have been choſen and ſworn by them. Dalt. c. 28. 2 Hawk. 63, 65. And by 13 & 14 Geo. II. c. 12. if a conſtable ſhall continue above a year in his office, the ſeſſions may diſcharge him, and put another in his place, till the court ſhall hold a leet. And if the court, or other judge, ſhall refuſe to diſcharge a conſtable, the King's Bench may compel them by mandamus. 2 Hawk. 65. If a conſtable be diſcharged without juſt cauſe, the court of King's Bench will by rule of court order him to be reſtored to his place. Bulſt. 174.

Constables *of the Caſtles*, in *Antiquity*, were keepers or governors of the caſtles of the king, or of great barons, who were frequently hereditary, or by feudal tenure; ſuch were the conſtable of the Tower, the conſtable of London, or Baynard's caſtle, the conſtables of the caſtles of Dover, Windſor, Cheſter, Caernarvon, and other caſtles in Wales; ſome of which offices, though not now hereditary, are remaining to this day. Their office ſeems to have been the ſame with that of the *caſtellani*, or governors of caſtles. Theſe conſtables are thoſe to whom Magna Charta (c. 17. 20.) refers; and who in the ſtat. of Weſtm. 1. (3 Ed. I.) c. 15. are called conſtables of fees, and there conſidered as keepers of priſons; a conſtituent part indeed of all ancient caſtles. 2 Inſt. 31. The ſtatute of 5 Hen. IV. c. 10. reciting the oppreſſions of theſe conſtables, and enacting that none be impriſoned but in the common gaol, ſeems to have put an end to a race of tyrants, who, by their miſconduct, had rendered themſelves odious to the people.

Constable *of France*. See Connetable.

Constable, *Provoſt of the*. See Provost.

Constable, in *Biography*, general of the Dominican order about the end of the ſixteenth century, was born at Ferrara, to which city he was conſtituted inquiſitor, and afterwards nominated maſter of the holy palace by pope Gregory XIII. In literary hiſtory he is known by a work entitled, "De cauſis in ſancto officio cognoſcendis," which related to the hiſtory of the dreadful tribunal invented by the founder of his order. His own zeal in the duties of the office to which he had been choſen was exemplary; and to exceſſive fatigue and over exertions occaſioned in viſiting on foot the monaſteries under his government, is to be aſcribed an illneſs that terminated in his death, at Venice on 17th of Sept. 1582. Moreri.

CONSTADT, or Kunstadt, in *Geography*, a ſmall town of Pruſſia, ſituated in Lower Sileſia, in the principality of Oels.

CONSTANCE, Costantz, or Costnitz, a conſiderable town of Wirtemberg, in the circle of Swabia, formerly a free imperial city, under the protection of Auſtria, delightfully ſituated at the north-weſtern extremity of the lake of Conſtance, where the Rhine iſſues out of it again; or between the two lakes; 45 miles N.E. from Zurich. N. lat. 47° 40′. E. long. 9° 12′. The fort of Peterhauſen defends it on the left ſide of the Rhine. "I was much afflicted," ſays Mr. Coxe, who viſited this place in 1776 (ſee Travels in Switzerland, vol. i. p. 16.) "with the ſolitary appearance of a town once ſo flouriſhing in commerce, and ſo celebrated in the annals of hiſtory. A dead ſtillneſs reigns throughout; graſs grows in the principal ſtreets; in a word, it wears the melancholy aſpect of being almoſt totally deſerted, and ſcarcely contains 3000 inhabitants. This city has endured a ſad reverſe of fortune; it was formerly in alliance with Zuric and Baſle; and, ſupported by their aſſiſtance, expelled the biſhop, and embraced the reformation. But the Proteſtant cantons being worſted in 1351; and the league of Smalcalde, of which Conſtance was a member, being defeated by Charles V., the town was obliged to ſubmit to the emperor," (having been placed under the ban of the empire in the year 1548, for deſerting the Roman Catholic religion), "and readmit the Catholic religion. From this period it loſt its independence." In 1549 it was placed under the power of the houſe of Auſtria by Ferdinand I.; and though the eſtates of Swabia refuſed their aſſent, the ſubjection was ratified by the diet at Augſburg. Being neglected by the houſe of Auſtria, the town fell to decay. Conſtance ſomewhat revived, and afforded the proſpect of becoming a commercial town, through the permiſſion granted by the emperor Joſeph, to the emigrants from Geneva, of ſettling and carrying on their trade and manufactures, with very conſiderable privileges; the principal of which were the following: *viz.* the right of purchaſing or building houſes; the free exerciſe of religion, entirely independent of the Catholic clergy; the power of erecting a tribunal for the purpoſe of deciding all affairs relative to their manufactures and commerce; exemption from ſerving in the militia and quartering ſoldiers, from all contributions during the ſpace of 20 years, from duties on their tools and utenſils; and the invariable eſtabliſhment of the ſtandard of the gold and ſilver employed in their manufactures. "Theſe favourable terms (ſays Mr. Coxe) ſigned on the 30th of June 1785, attracted ſo many ſettlers to Conſtance, that in my ſecond viſit to this place, on the 25th of October 1787, the new colony of Genevans conſiſted of 70 families, compriſing 350 perſons: among theſe were 54 watch-makers, who had introduced the different branches of manufacture which belong to their trade. Four hundred watches were already finiſhed, and above 1400 more were preparing. The emperor alſo has granted to Mr. Macaire the convent of Dominicans lately ſecularized, towards eſtabliſhing a manufacture of printed linens and cottons. The refectory is appropriated for the chapel of the new colony." "This convent, which was once the aſylum of monkiſh ſuperſtition, is now the ſeat of trade and induſtry; and it muſt ſuggeſt a pleaſing reflection to a philoſophic mind, that a ſucceſſor of Sigiſmond, who violated his word," (as in the caſe of Huſs) "ſhould have conſigned to a reformed eſtabliſhment that very convent in which the Bohemian divine was impriſoned, and from which he was led to the ſtake; and that the moſt enlarged principles of toleration ſhould be manifeſted in the ſame ſpot where perſecution was inculcated by precept and examples. It is the triumph of reaſon and religion over bigotry and intolerance." Since the period to which we have now referred, France has extended its revolutionary ſpirit and operations to the ſtates of Switzerland; and time muſt develope their effects on the liberty and commerce, and conſequent proſperity of the country. See Helvetic Confederacy and Switzerland. At preſent the manufactures and commerce of Conſtance are inconſiderable. Its celebrity is chiefly owing to a council held here from 1414 to 1418, which depoſed three popes, *viz.* John XXIII., Gregory XII., and Benedict XIII., who had ſet up againſt each other; appointed Martin V. in their room, condemned the doctrine of Wickliff, and committed his works to the flames, in 1415; and cauſed John Huſs and Jerome of Prague to be burnt, the former July 6, 1415, and the latter May 30, in 1416. At this council the aſſembled fathers on the 14th of June in 1415, paſſed the famous decree which took the cup from the laity in the celebration of the euchariſt, ordered that the Lord's ſupper ſhould be received by them only in one kind, *i. e.* the bread, and rigorouſly prohibited the communion in both kinds. The hiſtory of this council by L'Enfant is compoſed with great accuracy and elegance. A ſecond edition of this work appeared at Amſterdam in the year 1728, in 2 vols. 4to.: the firſt was publiſhed in 1714. For an account of the treaty at Conſtance, A. D. 1183; ſee the article City.

CONSTANCE, *Lake of*, ſeparates Switzerland from that part of Germany hitherto called the circle of Swabia.

It is divided into three parts: the upper part, which is the broadeſt, is called *Boden-See*, the middle part *Bodmer-See*, and the lower part *Zeller-See*.

The ſuperior lake is about 15 leagues in length, and 6 in its greateſt breadth. The borders conſiſt of gently riſing hills; on the left hand Swabia, and on the right Thurgau, with a variety of ſcattered towns, villages, and monaſteries, and delightful villas, which afford ſeveral views to thoſe who navigate the lake, that are truly enchanting. The form of the lake inclines to an oval, and the water is of a greeniſh hue. This lake, like all the other lakes of Switzerland, is conſiderably deeper in ſummer than in winter; a circumſtance which is owing to the firſt melting of the ſnow from the neighbouring mountains. It abounds with all ſorts of fiſh, and more particularly with the ſpecies of trout, called in its vicinity "Illankin," and by Linnæus SALMO *lacuſtris*. A little above Stein, which is an independent town, under the protection of Zurio; the Rhine widens conſiderably, and forms the inferior lake of Conſtance, or the *Zeller-ſee*, which is divided into two branches; from Stein to Conſtance is about 16 miles, and from the latter to Zell, its greateſt breadth, about 10.

Near Merſbourg the lake of Conſtance is ſaid to be 350 fathoms deep. This great depth is extremely advantageous to commerce, the lake being navigated by veſſels of 100 tons and upwards. There are two iſlands in its middle, on one of which is the town of Lindau, formerly a free imperial city, but belonging now to the king of Bavaria, who, by the treaty of the confederation of the Rhine, has engaged to have it fortified and provided with artillery eſtabliſhments. On the other iſland, about a mile in circumference, is the town of Meinau, which belonged to the knights of the Teutonic order, and whoſe ſituation is delightful.

The Rhine enters the lake of Conſtance at its ſouth-eaſtern extremity, and iſſues out of it again at the north-weſt, not far from Stein. There is an ancient, and generally accredited tradition, that the Rhine, in croſſing the lake in all its length, does not mix with its water. The ſame is ſaid of the Rhone, which runs through the lake of Geneva. Pliny the Elder, and Ammianus Marcellinus, are the authors of theſe fables. It is true that the two rivers are diſtinctly ſeen ſome time after their entrance into the lakes, but the difference of colour vaniſhes as ſoon as they have depoſited the ſand which they carry. Mr. Coxe, ſeated on board a veſſel on the lake, in vain attempted to diſtinguiſh the waters of the Rhine from thoſe of the lake. The river, in its courſe from the ſuperior lake, being exactly of the ſame beautiful greeniſh colour as the inferior lake into which it flows; it is evident that the one can never be diſtinguiſhed from the other. Probably, upon its firſt entrance into the ſuperior lake it is troubled, and, conſequently, for ſome diſtance, its current may be eaſily traced; but it purifies itſelf by degrees, and becomes an indiſtinct part of the great body of water.

Of no better foundation is the report that the lake of Conſtance never freezes. Wagner aſſures that it was frozen in 1572 and 1596, when two inhabitants of Conſtance walked over the lake on the ice, meaſured it, and found it to be 7265 fathoms long, from Romizhorn to Bouchorn, which is not its whole length.

CONSTANCY, in a general ſenſe, denotes immutability; but in ethics, or the philoſophy of the human mind, the term implies reſolution or ſteadineſs, particularly under adverſe trials and ſuffering. It was the ſaying of a heathen philoſopher, that there cannot be imagined upon earth a ſpectacle more worthy of the regard of the creator, intent on his works, than a brave man ſuperior to his ſufferings. Nothing, indeed, can be more noble or honourable, than to poſſeſs courage ſufficient for executing the injunctions of reaſon and conſcience; for maintaining the dignity of our nature, and the ſtation aſſigned us; and for being ſo much unafflicted by poverty, pain, and even death itſelf, as not to do any thing that is reproachful or ſinful in order to avoid them. To poſſeſs this temper, is to be great above title and fortune; and manifeſts a mind of heavenly extraction, and worthy of the offspring of the deity. Of this kind, many illuſtrious inſtances occur in hiſtory, and particularly in the hiſtory of the Chriſtian church, and of the laſt moments of confeſſors and martyrs.

CONSTANS I., FLAVIUS JULIUS, in *Biography*, third ſon of Conſtantine the Great, by Fauſta, was born A. D. 320, and was created Cæſar at ſix years of age. Upon the death of his father in 337, Conſtans ſucceeded to the ſovereignty of Italy, Africa, and the weſtern Illyricum, as his ſhare of the empire. He had enjoyed his power but three years, when he was attacked by his brother Conſtantine, whom he defeated and ſlew.

Conſtans, by this victory, became poſſeſſor of Gaul, Spain, and Britain; and in his turn, attacked the Franks, whom he humbled, and the Scots, which probably did not end much to his credit, as no notice is taken of the fact by his early biographers. Neverthleſs, the prince was elated by the ſucceſs of his arms, and aſſumed a degree of pride on the occaſion, which would have ill become any man, and in him was rendered quite contemptible, owing to his want of talents and application. He was, moreover, a ſlave to his paſſions, and allowed himſelf in acts of voluptuouſneſs, that drew down upon him the indignation of the people. Magnentius, an ambitious ſoldier, encouraged by popular diſcontents, was reſolved to aſſert the honour of the Roman name. A conſpiracy was formed, and Marcellinus, count of the ſacred largeſſes, who had already ſupplied, with a liberal hand, the means of ſeduction, under pretence of celebrating his ſon's birth-day, gave a ſplendid entertainment: the intemperance of the feaſt was artfully protracted till a late hour, and the unſuſpecting gueſts were tempted to indulge themſelves in a dangerous freedom of converſation. On a ſudden, the doors were thrown open, and Magnentius, who had retired for a few moments, returned into the apartment inveſted with the diadem and purple. The conſpirators inſtantly hailed him with the titles of Auguſtus and emperor. The guards immediately took the oath of fidelity, and ere the dawning of the day, Magnentius became maſter of the troops and treaſure of the palace and city of Autun. Conſtans, who was purſuing his pleaſure in an adjacent foreſt, being informed of the fact, threw off the imperial robes, and fled towards Spain; but before he could reach the ſea-port, where he intended to embark, he was overtaken by a party of cavalry near Helena, at the foot of the Pyrenées, and put to death. Gibbon. Univer. Hiſt.

CONSTANS II. grandſon of Heraclius, emperor of the Eaſt, was raiſed to the throne in 641, after the ſenate had depoſed the uſurper Heracleonas, and his mother Martina. He was then only in his twelfth year, yet before the Byzantine ſenate, he delivered an oration that did him great credit. Having returned thanks for the juſt puniſhment of the aſſaſſins, who had intercepted the faireſt hopes of his father's reign, he added "By the divine providence, and by your righteous decree, Martina and her inceſtuous progeny have been caſt headlong from the throne. Your majeſty and wiſdom have prevented the Roman ſtate from degenerating into lawleſs tyranny. I therefore exhort and beſeech you to ſtand forth as the counſellors and judges of the common ſafety." The ſenators were gratified by the reſpectful addreſs of their ſovereign; but Conſtans was anxious to ſecure the crown that had ſuddenly devolved on him. He obliged his elder brother Theodoſius to take holy orders, which rendered him incapable of civil government. The young emperor was not ſatisfied with this act, which was regarded as a profanation of the ſacraments, but he cauſed Theodoſius to be put to death. The act was ſcarcely perpetrated before the execrations of his ſubjects, joined to the agonies of remorſe, rendered life a burden. He could no longer bear to reſide in the capital that had been the witneſs of a baſe and infamous fratricide. He became a voluntary and perpetual exile; and embarking for Greece, diſplayed the hatred which he felt, and was conſcious that he inſpired, by ſpitting againſt the walls of Conſtantinople as he left them. After paſſing the winter at Athens, he viſited various parts of Italy, and concluded a pilgrimage of diſgrace, by fixing his reſidence at Syracuſe. Conſtans eaſily fled from the imprecations of an injured people, but he could not forget what he had done. The remorſe of his conſcience created a phantom that purſued him wherever he went: the image of his murdered brother was ever before his eyes, preſenting to his lips a cup of blood, and ſaying, or ſeeming to ſay, "Drink, brother, drink,"—"a ſure emblem," ſays the hiſtorian, "of the aggravation of his guilt, ſince he had received from the hands of the deacon, the myſtic cup of the blood of Chriſt." Conſtans, however, did not reſign the cares of government. He took part in ſome wars carried on in Italy, and having been ſucceſsful, entered the capital with great pomp, and was met by the pope and clergy at a diſtance from the city. In return for this mark of reſpect, he plundered Rome, and ſent its wealth and ornaments to Conſtantinople. He then departed for Syracuſe, where he reſided five years, oppreſſing the people, and hated by thoſe about him. Domeſtic treaſon put an end to his life; he was aſſaſſinated while he was in the bath, in in the year 668, after a miſerable reign of 27 years. Gibbon. Univer. Hiſt.

CONSTANT, David, was born at Lauſanne, in Switzerland, in the year 1638, and became diſtinguiſhed as a proteſtant divine, and profeſſor of theology. He was indebted to his own country for the rudiments of uſeful knowledge, and was afterwards a ſtudent at Herborn in Germany, from which place he went to Groningen, Leyden, and Paris, for farther improvement. At Paris, he became acquainted with many very celebrated members of the reformed church, and having laid the foundation of ſolid learning, and formed a connection with ſeveral worthy characters, he returned to Switzerland in the year 1658, was ordained miniſter according to the calviniſtic form, and undertook the charge of a church at Copet. Here he cultivated a literary intimacy with Turretin, Tronchin, and other profeſſors in the univerſity of Geneva, and with Bayle, the celebrated hiſtorian, but who at that time was tutor in the family of count de Donha, baron of Copet, the patron of David Conſtant. On a vacancy at the college of Lauſanne, Conſtant was appointed tutor to the firſt claſs, by the magiſtrates of Berne, and was afterwards elected profeſſor of moral philoſophy and the Greek language. The important duties of theſe ſtations he diſcharged with high honour to himſelf, and to the advantage of thoſe placed under his inſtructions; his vacant hours were employed in editing ſome of the claſſics, or on original works. By his contemporaries he was much reſpected; they regarded him as a man of conſiderable literary acquirements, poſſeſſed of a ſolid judgment and a correct taſte. In the year 1700, he was choſen profeſſor of theology, a ſituation which he retained until he was eighty-nine years of age, when he reſigned in favour of a ſucceſſor, reſerving to himſelf, even then, the right of giving his aſſiſtance and advice at the public meetings of the college. He died in 1733, having attained the venerable age of ninety-five. He publiſhed new editions of Florus; of Cicero's ſmaller pieces, and of various other pieces adapted to the uſe of ſchools. His original writings were reſpectable; they were diſſertations on curious theological ſubjects. We have alſo "Syſtema Ethico-theologicum," printed at Lauſanne, 1695; a work "De Juramentis;" and another "On Providence."—Moreri.

Constant *quantity*, in *Geometry*, that which remains the ſame, while others increaſe or decreaſe. Thus the ſemidiameter of a circle is a *conſtant quantity;* for while the abſciſs and ſemi-ordinates increaſe, it remains the ſame.

Constant *winds*. See Wind.

CONSTANTIA, in *Ancient Geography*, a town of Valeria, in the vicinity of the Danube.—Alſo, a town of Thrace, in the territory of mount Rhodope.—Alſo, a town of Aſia, in Meſopotamia; ſaid by Ammianus Marcellinus to have been *Amida*, which was enlarged by the emperor Conſtantine, and aſſumed his name.—Alſo, a name given to Majumas, the port of Gaza, after Conſtantine raiſed it to the rank of a town and gave it the name of his ſon.—Alſo, a name given to the town of Salamine.—Alſo, a name aſſigned by Conſtantine to the town of Arelata (Arles), according to Auſonius, cited by Scaliger.

Constantia *Caſtra*, a town of Gaul, in the ſecond Lyonnenſis; now *Coutances*.

Constantia, in *Geography*, a diſtrict of the Cape of Good Hope, a mile and a half from Alphen, cloſe under the mountains, about midway between Table bay and Falſe bay, conſiſting of two farms which produce the far-famed Cape or Conſtantia wine, ſo remarkable for its peculiar rich flavour and ſweetneſs. One of the farms where the white wine is made is called *Little Conſtantia;* the other produces red. There are only from fifty to one hundred caſks, of 154 gallons each, made annually of the genuine Conſtantia wine. The grape is the muſcadel, and the rich quality of the wine is owing partly to the ſituation and ſoil of the vineyards, and partly to the care taken in manufacturing the wine. No ſtalks, and no fruit but ſuch as is full ripe, are ſuffered to go under the preſs; precautions rarely taken by the other farmers of the Cape, who make annually about ſix hundred 154-gallon caſks of the common Cape wine, which, however, is frequently brought into the European markets, under the name of Conſtantia wine. The muſcadel grape grows at every farm: and at ſome farms in Drakenſtein, the wine preſſed from it is equally good, if not ſuperior, to the Conſtantia, though ſold, on account of the name of the latter, at one ſixth part of the price. This wine ſells at the Cape for 70 or 80 rix-dollars for the half-aum, which ought to contain 20 gallons; but the avaricious diſpoſition of the proprietors, has led them to fabricate falſe caſks, few of which that come to England being found to meaſure more than 17 or 18 gallons, and many not above 16. When they find that the wine is to be ſent abroad, they adulterate it with ſome other wine. For, according to their own returns, the quantity exported and conſumed in Cape Town, as in the caſe of Madeira wine, greatly exceeds the quantity manufactured.

The following table ſhews the quantity of Conſtantia wine exported in four ſucceſſive years.

Years.	Half Aums.	Value.
1799	157	11,752
1800	188	14,070
1801	173	13,007
1802	210	15,745
In 4 years.	728	54,574 R. D.

Barrow's Travels in S. Africa, vol. ii. p. 290.

CONSTANTINA, or CONSTANTINE, the eaſtern province of the kingdom of Algiers, which ſee. This province, which is the largeſt and richeſt of the four provinces into which Algiers is commonly divided, (the three others being Maſcara, the territory of the city of Algiers, and Titeri,) lies betwixt the meridians of the rivers Booberak and Zaine, which ſeparates it from Tunis, and is bounded on the north by the Mediterranean, on the eaſt by the kingdom of Tunis, on the ſouth by Biledulgerid, and on the weſt, in its greateſt extent, by the river Malva, or by the territory of Algiers, &c. It is nearly equal in extent to the two weſtern and ſouthern provinces, being, by Dr. Shaw's ſtatement, 230 miles in length, and more than 100 in breadth; and far ſurpaſſing them in wealth and ſtrength, as well as in the number and goodneſs of its cities. The tribute collected by the viceroy of this province, according to Dr. Shaw, is proportionably greater. For whilſt the Titeri bey brings every year into the treaſury of Algiers little more than 12,000 dollars, each dollar being 3*s.* and 4*d.* or 6*d.*, and the Tlemſan bey from 40 to 50 thouſand; the viceroy of Conſtantina never pays in leſs than 80, and ſometimes 100 thouſand. The ſea-coaſt of this province, from the Booberak to Boujeiah, and from thence almoſt entirely to Bona, is rocky and mountainous; and the whole tract which lies between the meridians of the rivers Booberak and Zhorre, from the ſea-coaſt to the parallels of Seteef and Conſtantina, is, for the moſt part, a continued chain of exceedingly high mountains; few of whoſe inhabitants, from the ruggedneſs of their ſituation, pay any tribute to the Algerines. Near the parallels of Seteef and Conſtantina it is diverſified with a beautiful interchange of hills and plains, which afterwards become leſs fit for tillage, till it terminates, upon the Sahara, in a long range of mountains, ſuppoſed by Dr. Shaw to be the *Buzara* of the ancients. The diſtrict of *Zaab* (which ſee) lies immediately under theſe mountains; and beyond Zaab, at a great diſtance in the Sahara, is Wadreag, another collection of villages. This part of the eaſtern province, including the parallel of Zaab, anſwers to the *Mauritania Sitifenſis*, or the firſt Mauritania, as it was called in the middle age. The mountains are inhabited by free Arabian and Mooriſh tribes, which from time to time have proved formidable enemies to the power of Algiers. The moſt remarkable places are *Boujeiah* or BUGIA, CULLU, BONA, LA CALLE, the iſland of TABARCA, and CONSTANTINA; which ſee reſpectively.

CONSTANTINA, *Conſtantine*, formerly *Cirta*, is one of the moſt conſiderable cities of ancient Numidia, the capital of the above-deſcribed province, and the reſidence of the bey. Next to Algiers, it is the moſt populous city in the Algerine dominions. For a particular account of it, ſee CIRTA.

CONSTANTINA, a town of Spain, in Andaluſia; 50 miles S.W. of Cordova, and 42 N.N.E. of Seville.

CONSTANTINA, in *Ancient Geography*, a town of Phœnicia.—Alſo, a town of Aſia, in Meſopotamia.

CONSTANTINE I., FLAVIUS VALERIUS CONSTANTINUS, in *Biography*, the firſt Chriſtian emperor, and ſurnamed the GREAT, was ſon of Conſtantius Chlorus by Helena. The celebrity to which this prince attained, has rendered poſterity attentive to the moſt minute circumſtances of his life and actions. The place of his birth, and the condition of his mother, have been ſubjects of warm, not to ſay violent, diſputes. According to Mr. Gibbon, Helena was the daughter of an inn-keeper, and Naiſſus in Dacia was the birth place of her ſon, the ſubject of this article, about the year 274. In his youth he diſcovered little inclination to improve his mind by the acquiſition of knowledge; but the comelineſs of his figure, the dexterity which he exhibited in all manly exerciſes, and his known courage and affability, rendered him a favourite with the army and the people. He was about eighteen years of age when his father was promoted to the rank of Cæſar: this event was attended with his mother's divorce, in order to make way for the ſecond wife of Conſtantius, who could boaſt of an alliance with the imperial race. By this act the noble-minded Conſtantine was reduced to a ſtate of diſgrace and humiliation. Indignant, probably, at the baſe conduct of his father, he remained in the ſervice of Diocleſian, and ſignalizing himſelf in the wars of Egypt and Perſia, he was raiſed to the rank of tribune of the firſt order. The popularity of this young man rendered him an object of jealouſy to Galerius, through whoſe intereſt he had already been denied the rank of Cæſar. Endangered by the power and wiles of his opponent, and being ſent for by Conſtantius, his father, whoſe health was daily declining, he ſecretly left Nicomedia, where he then was, and travelled with all expedition to Boulogne, and embarked with Conſtantius for Britain. The expedition was proſperous, and they eaſily obtained a victory over the Caledonians; but it was the laſt exploit of Conſtantius. He died at York, in the year 306, within little more than a year after he had received the title of Auguſtus. His death was immediately ſucceeded by the elevation of Conſtantine, who was proclaimed emperor by the army. The throne was the object of his ambition; and he knew too well the character of Galerius, the colleague of his late father, to heſitate as to the part he muſt take in this criſis. He was ſatisfied that if he wiſhed to live, he muſt reſolve to reign. At firſt he affected to reſiſt the choice of his people, and wrote a reſpectful letter to the emperor of the Eaſt, acquainting him with the event. The earlieſt emotions of Galerius were thoſe of ſurpriſe, diſappointment, and rage: he threatened to commit to the flames the letter, and him that brought it. Upon farther deliberation, he reſolved not to conteſt his ſucceſſion to the ſovereignty of the provinces beyond the Alps; but conferred on him the title of Cæſar, reſerving that of Auguſtus to his favourite Severus. Conſtantine, who already poſſeſſed the ſubſtance, expected without impatience an opportunity of obtaining the honours, of ſupreme power; and accordingly employed himſelf ſome years in governing and ſecuring the dominions fallen to his ſhare. In defending his own rights, he was often betrayed into acts of cruelty, unworthy of a great mind. Contending with the Franks, he took two of their kings, whom he barbarouſly expoſed to wild beaſts in the amphitheatre of Treves: in ſome inſtances where he was victorious, he ſpared neither ſex nor age; exhibiting a ferocity that ſeems ill to accord with the general tenor of his character, to which he was probably prompted by the ſuppoſition, that upon a barbarous foe all kinds of barbarity were allowable. In 307 he married Fauſta, daughter of Maximian, who had reſumed the purple; but he took no part in the fortunes of his father-in-law, who was ever engaged in warfare, till he became himſelf Conſtantine's open enemy, and endeavoured to diſpoſſeſs him of his rightful authority. Under theſe circumſtances he was delivered into the hands of his ſon-in-law, who ſhewed him no other favour than that of allowing him the choice of the manner in which he would die: Maximian ſtrangled himſelf in the year 310.

Shortly after this event, which was little creditable to the feelings of Conſtantine, or to the filial piety of Fauſta, who took no means to ſoften the reſentment of her huſband, a civil war broke out. Maxentius, who had reigned in conjunction with Conſtantine, now laid claim to the monarchy of the whole Weſt, and made preparations for an invaſion of Gaul. Conſtantine relying as well on his own talents, as on the hatred borne to his rival, reſolved to anticipate the attack, and to carry the war into the heart of Italy. The armies of Maxentius, amounted to one hundred and ſeventy thouſand foot, and eighteen thouſand horſe. The wealth of Italy ſupplied the expences of the war, and the adjacent provinces were exhauſted to form magazines of corn and other kinds of proviſions. The whole force of Conſtantine conſiſted of ninety thouſand foot, and eight thouſand horſe; a large part of which was neceſſary to the defence of his other dominions. At the head of forty thouſand ſoldiers, he marched to encounter an enemy, whoſe numbers were at leaſt four times ſuperior to his own. Conſtantine had been trained from his earlieſt youth to war, to action, and to military command, and his troops were in the higheſt ſtate of diſcipline: theſe he diſpoſed with conſummate ſkill, and for himſelf he choſe the poſt of honour and danger. Diſtinguiſhed by the ſplendor of his arms, he charged, in perſon, the cavalry of his rival, and his irreſiſtible attack determined the fortune of the day. The victory was complete, and the diſmayed followers of Maxentius ruſhed by thouſands into the Tyber. The emperor himſelf attempted to eſcape back into the city over the Milvian bridge, but the crowds which preſſed together through that narrow paſſage, forced him into the river, where he was immediately drowned by the weight of his armour. His body which had ſunk deep into the mud, was found the next day; and the ſight of his head, when it was expoſed to the eyes of the people, convinced them of their deliverance, and led them to acknowledge as their ſovereign Conſtantine, who thus atchieved by his valour and high talents the moſt ſplendid enterprize of his life. It was previous to this battle, A. D. 312., that hiſtorians aſſign the date of Conſtantine's converſion to Chriſtianity, who had never before diſcovered religious principles of any kind. A ſplendid miracle is mentioned as the immediate inſtrument of this change. Dr. Lardner, indeed, offers ſome reaſons why Conſtantine could not well have remained through life without ſome religious impreſſions; he is however willing to follow the account of Euſebius, who ſays, that about the period of the war with Maxentius, the emperor was led to conſider that he ſtood in need of more powerful aſſiſtance than military forces; he therefore ſought for a God that ſhould be his helper. The hiſtorian goes on to ſay, that in part of his march, as the day was declining, there appeared to the ſight of Conſtantine, and to that of all his army, a luminous croſs above the ſun, with the inſcription *τȣτῳ νικα*, *by this conquer*; that the monarch not comprehending the meaning of this ſign was farther inſtructed, in the following night by a viſion of Chriſt himſelf, bearing his croſs, and directing him to take a ſimilar ſtandard, under which he ſhould march to victory. In the morning Conſtantine communicated this wonderful circumſtance to his friends; and ſending for ingenious workmen, he gave them a deſcription of the ſign, and ſaw them make one like it in gold and precious ſtones; which, ſays Euſebius, "we have ſeen." Much has been ſaid reſpecting this ſurprizing phenomenon. By ſome the whole is regarded as a fiction, a ſtratagem and political device of Conſtantine, yet it is related by Euſebius a grave hiſtorian, who declares that he had it from the emperor, who confirmed the narration by an oath. By Fabricius, we are told, that the appearance in the heavens was generally looked upon as a reality, and a miracle: but for his own part, he is inclined to conſider it as the reſult of a natural phenomenon in a ſolar halo; he accordingly admits of the reality of the phenomenon, but does not ſuppoſe it to be properly miraculous. Upon a full and candid review of the evidence, Dr. Lardner, whom we have before quoted, and than whom no one was a better judge of human teſtimony, ſeems inclined to doubt the relation given by the emperor, upon whoſe ſole credit the ſtory is recorded, though it was twenty years after the event, when Euſebius wrote his account, during which period he muſt have heard it frequently from eye-witneſſes, if the emperor's relation were accurate that the appearance was viſible to his whole army as well as to himſelf. The oath of Conſtantine, on the occaſion, with Dr. Lardner, brings the fact into ſuſpicion, and another ſtriking circumſtance is that Euſebius does not mention the place where this wonderful ſight appeared. Without, however, entering, at preſent, farther into the diſcuſſion, which we ſhall refer to the article Cross; we may obſerve, that Euſebius has led us to the period, when the ſign of the croſs began to be made uſe of by Conſtantine, among his armies, and at his battles; this was probably the day before the laſt battle with Maxentius, fought on the 27th of October, 312. About this period, it is admitted, that Conſtantine became a Chriſtian, and continued ſo the remainder of his life, taking care alſo to have his children educated in the ſame principles. His converſion ſeems to have been partly owing to his own reflections on the ſtate of things, partly to converſation and diſcourſe with Chriſtians, with whom, the ſon of Conſtantius, their friend and favourer, muſt have been ſome time acquainted, but perhaps, chiefly to the ſerious impreſſions of his early years, which being once made can never be wholly obliterated. Conſtantine was however a politician as well as a Chriſtian, and he probably hit upon this method to reconcile the minds of his army, to the important change in their religious profeſſion and habits, as well as making uſe of it as a mean of ſucceſs in his deſigns againſt his enemies, for which purpoſe he rightly judged, that the ſtandard of the croſs, and the mark of it as a device on his ſoldier's ſhields, would be of no ſmall ſervice.

We muſt now return to Conſtantine in the character of a victorious general. After the battle, he entered the capital in triumph, wholly deſtroyed the family of his rival, but refuſed to include among the victims, many whom the Romans would gladly have ſacrificed to their abhorrence of the late tyranny. He diſbanded and diſperſed the pretorian guards which had ſo often made and murdered emperors: he recalled many who had been baniſhed, and reſtored to them their eſtates: he diſcouraged informers, and promoted the welfare of the city. The ſenate immediately paſſed a decree, conferring on him the firſt rank among the three Auguſti, who then were maſters of the world: Licinius and Maximin were the other two. Africa readily followed Italy in recognizing the ſovereignty of the conqueror. To Licinius, with whom he had an interview, he gave his ſiſter Conſtantia in marriage, in order to ſtrengthen his own hands. From Milan, where the two emperors iſſued an edict under their joint authority, allowing a general toleration in religious matters within their dominions, Conſtantine was called by an attempt of the Franks to croſs the Rhine. Over theſe he gained a complete victory, and made many priſoners, whom, as in former inſtances, he expoſed to wild beaſts. In the mean time a civil war aroſe between Maximin and Licinius, which terminated in the deſtruction of the former, and the extirpation of his whole family.

Conſtantine and Licinius were now maſters of the world, but they did not long continue united. A war broke out between them in the year 314, but the reſult of ſeveral battles was decidedly in favour of Conſtantine. Licinius ſued for peace, which he obtained, and which continued eight years. In 323 another war was excited between the emperors. Licinius had long been hoſtile to the Chriſtians, whoſe affections he had alienated, and who looked up to Conſtantine as their patron, and the head of their religion. Aware of this circumſtance, and relying on his own ſuperiority, as a military commander, Conſtantine began the quarrel. Under the banner of the croſs, and accompanied by biſhops and other miniſters of their holy religion, he went out with 130,000 well-diſciplined and well-accoutred ſoldiers to meet his rival, who waited his arrival in the vicinity of Adrianople. Conſtantine was again victorious: Licinius fled to Byzantium, and when he found that place no longer tenable againſt the power of his enemy, he withdrew to Chalcedon, and from thence, after hazarding another battle, in which he was alſo unſucceſsful, to Nicomedia; where, by the interceſſion of his wife, he obtained a ſolemn promiſe of having his life ſpared, on the condition of his renouncing all claims to ſovereignty. To the diſgrace of Conſtantine impriſonment and death ſoon followed the humiliation of his rival. This deed has been juſtified on the plea that the fallen emperor had engaged in a treaſonable correſpondence againſt the reigning ſovereign, but ſufficient evidence of the fact was not adduced. The ſon of Licinius was alſo ſacrificed to the jealouſy of Conſtantine, who, by theſe atrocious means, delivered himſelf from all dread of oppoſition. An arbitrary prince ſeldom finds any difficulty in freeing himſelf from his enemies, but Conſtantine with all his powers, could neither foreſee, nor prevent, thoſe domeſtic calamities to which he ſhortly became the prey. Criſpus, his ſon, by a former wife, was viewed, by his mother-in-law Fauſta, as the chief obſtacle to the future greatneſs of her own children. She inſinuated into the breaſt of Conſtantine ſuſpicions of his ſon's loyalty, and is ſaid alſo to have brought a charge againſt him of having attempted her own chaſtity. Criſpus was examined, impriſoned, and put to death in the year 326. His grandmother Helena, convinced of his innocence, reſolved to be revenged for his hard fate, and found means of convicting the empreſs of an adulterous connection with a ſlave of the palace, for which ſhe was ſuffocated in the ſteam of a hot bath. From theſe circumſtances, and from the contempt which he ſhewed for the pagan rites, the emperor became unpopular with the people and the ſenate. On his part there was no perſonal attachment to the ancient metropolis, and he was reſolved to perpetuate his name by the foundation of a new city. After much deliberation he fixed on Byzantium, which he had once beſieged, as the imperial city that ſhould, with future ages, give him celebrity and renown. See CONSTANTINOPLE.

In the year 331 Conſtantine was involved in a war with the Goths, who at firſt were ſucceſsful againſt his power, but were, at length, defeated and compelled to agree to ſuch terms as the victor thought proper to propoſe. Conſtantine, by chaſtiſing the pride of the Goths, and by accepting the homage of a ſuppliant nation, vindicated the majeſty of the Roman empire; and ambaſſadors from Ethiopia, Perſia, and the moſt remote countries of India, came to congratulate him on the peace and proſperity of his government; and he ſeems to have enjoyed as uninterrupted a ſhare of felicity, as a man ſituated as he was could reaſonably expect. He attained to the thirtieth year of his reign, a period which none of his predeceſſors, ſince Auguſtus, had been permitted to celebrate. Conſtantine ſurvived that ſolemn feſtival about ten months, and, at the age of ſixty-four, after a ſhort illneſs, he ended his memorable life at a palace in the ſuburbs of Nicomedia, whither he had retired for the benefit of the air, and with the hope of recruiting his exhauſted ſtrength by the uſe of the warm bath. The demonſtrations of grief, or at leaſt of mourning, ſurpaſſed whatever had been practiſed on any former occaſion. The body of the deceaſed emperor was tranſported to the city which was deſtined to preſerve the name and memory of its founder: there it was adorned with the ſymbols of greatneſs, and depoſited on a golden bed in one of the apartments of the palace, which was ſplendidly illuminated and furniſhed for the purpoſe. Every day, at the appointed hours, the officers of ſtate, approaching the perſon of their ſovereign, offered the ſame reſpectful homage to his dead body as they had been accuſtomed to preſent to him during his life, ſo that it has been ſaid Conſtantine alone, by the peculiar indulgence of heaven, reigned after his death.

It remains now to give a general eſtimate of the character of this great man, who was unqueſtionably the moſt ſplendid among the Roman emperors. It is no wonder that a prince who removed the ſeat of empire, and introduced ſuch important changes into the civil and religious conſtitution of his country, ſhould have fixed the attention, and divided the opinions of mankind. By certain claſſes of Chriſtians he has been regarded as the deliverer and defender of the church, and has been decorated with every attribute of a hero, and even of a ſaint: by others he has been conſidered as the real, though without any ill intentions on his part, enemy to the cauſe of true Chriſtianity, by incorporating it with the civil government of the world: by contemporary hiſtorians who did not embrace the religion of Chriſt, Conſtantine was compared to the moſt abhorred of thoſe tyrants, who, by their vices and weakneſs, diſhonoured the imperial purple.

Conſtantine was, in perſon, remarkably tall, of a comely and majeſtic preſence, and great bodily ſtrength. The general tenor of his life proves that he was a perſon of no mean capacity: the atchievements and ſucceſs of Conſtantine do not belong to men of weak and irreſolute minds. His mind indeed was equal to his fortune, great as it was: his valour was tried and approved frequently in his youth, and was conſpicuous on all proper occaſions throughout his whole life: his chaſtity, juſtice, and prudence, are commended by thoſe of his biographers, who, on account of a difference in religion, were not diſpoſed to flatter him: his many acts of bounty to the poor, and his juſt edicts are arguments of a merciful diſpoſition, and a love of juſtice. According to Euſebius the palace of Conſtantine was converted into a church; and the emperor himſelf chearfully led the way to thoſe that aſſembled there with him. Taking the ſacred books into his own hands, he attentively read and meditated upon the divine oracles; and then recited the uſual prayers with thoſe who were met together. Conſtantine beſides prayed daily in private in his cloſet. In time of war he had a chapel at a ſmall diſtance from his camp for the performance of religious duties, eſpecially before battle, ſeeking thereby the divine protection and bleſſing. He taught even his heathen ſoldiers a form of prayer, in which they worſhipped the one true God. Theſe and many other inſtances of the Chriſtian temper are aſcribed to the emperor by Euſebius. By our own hiſtorian, the early part of his life is highly panegerized: "He delighted," ſays Mr. Gibbon, "in the ſocial intercourſe of familiar converſation; and though he might ſometimes indulge his diſpoſition to raillery with leſs reſerve than was required by the ſevere dignity of his ſtation, the courteſy and liberality of his manners gained the hearts of all who approached him. The diſadvantage of an illiterate education had not prevented him from forming a juſt eſtimate of the value of learning; and the arts and ſciences derived ſome encouragement from the munificent protection of Conſtantine. In the diſpatch of buſineſs, his diligence was indefatigable; and the active powers of his mind were almoſt continually exerciſed in reading, writing, or meditating: in giving audience to ambaſſadors, and in examining the complaints of his ſubjects. Even thoſe who cenſured the propriety of his meaſures were compelled to acknowledge, that he poſſeſſed magnanimity to conceive, and patience to execute, the moſt arduous deſigns, without being checked either by the prejudices of education, or by the clamours of the multitude. In the field, he infuſed his own intrepid ſpirit into the troops, whom he conducted with the talents of a conſummate general; and to his abilities, rather than to his fortune, we may aſcribe the ſignal victories which he obtained over the foreign and domeſtic foes of the republic. He loved glory, as the reward, perhaps as the motive, of his labours. The boundleſs ambition, which, from the moment of his accepting the purple at York, appears as the ruling paſſion of his ſoul, may be juſtified by the dangers of his own ſituation, by the character of his rivals, by the conſciouſneſs of ſuperior merit, and by the proſpect that his ſucceſs would enable him to reſtore peace and order to the diſtracted empire." As he advanced in life, his character was leſs reſpectable, his actions leſs honourable. The oſtentatious grandeur of his court, and his magnificent buildings, were ſupported by taxes which bore very heavily on the people, and in his old age he was charged with prodigality and rapacity. Eutropius ſays, that Conſtantine, "in the early parts of his reign, might be compared to the beſt princes, in its concluſion to the indifferent ones." And Dr. Lardner, who took great pains to underſtand and appreciate the worth of this emperor, obſerves, with his uſual candour, that "we ſhould be willing to make allowances in favour of princes, and eſpecially of long reigns. It is next to impoſſible for human wiſdom and diſcretion, in the courſe of many years filled with action, not to be ſurpriſed into ſome injuſtice, through the bias of affection, or the ſpecious ſuggeſtions of artful and deſigning people. Though, therefore, there may have been ſome tranſactions in this reign which cannot be eaſily juſtified, and others that muſt be condemned, yet we are not to conſider Conſtantine as a cruel prince or a bad man." Gibbon. Lardner. Jortin. Univer. Hiſt.

Constantine II., the eldeſt of the three ſons of Conſtantine the Great, was born in the year 316, and, by the indulgence of his father, was admitted at a very tender age to ſhare the adminiſtration of the empire. He and his brothers may be ſaid to have ſtudied the art of reigning at the expence of the people entruſted to their care. During his father's life-time, the younger Conſtantine was appointed to hold his court in Gaul: and upon his death in 337, he ſucceeded to the government of Gaul, Spain, and Britain; to him alſo was aſſigned the city of Conſtantinople, with a certain ſuperiority of rank above his brothers. During his ſhort reign, he did little that has been deemed worthy of hiſtorical record. Diſſatisfied with the ſhare of empire allotted to him, he was deſirous of poſſeſſing the provinces of Africa, which had been given to Conſtans. His ſolicitations were in vain: determining, therefore, to wreſt by force, what he could not obtain by argument, at the head of a tumultuary band, he invaded the dominions of Conſtans, and laid waſte many parts of the country. The meaſures of his brother were directed with more prudence; and Conſtantine, by too great eagerneſs, was betrayed into an ambuſcade, which had been concealed in a wood, where he and his attendants were ſurrounded and ſlain, A. D. 340. His body was afterwards found in the obſcure ſtream of Alſa, and obtained a place in the imperial ſepulchre; but his provinces transferred their allegiance to the conqueror. Contemporary hiſtorians ſpeak of Conſtantine as a prince of great accompliſhments; but his conduct towards his brother met with a puniſhment which neither merited nor obtained the pity of ſurvivors.

Constantine III., the next emperor of this name, was the ſon of Heraclius by Eudoxia, and ſucceeded his father in 641. Of him more cannot be well ſaid than that he reigned three months, and died in his 30th year, either by diſeaſe, or by poiſon, ſuppoſed to have been adminiſtered by his mother-in-law.

Constantine IV. ſucceeded his father, Conſtans II., in the year 668. Very ſoon after he came to the throne, he went to Sicily, with a view of puniſhing his father's murderers, and to depoſe the uſurper whom they had eſtabliſhed. His enterprize was ſucceſsful: but upon his return to Conſtantinople, he was ſcarcely recognized, on account of the alteration in his beard; hence he obtained the appellation of the *bearded*. In this reign the Saracens invaded Africa, Sicily, and Cilicia, and at length laid ſiege to Conſtantinople. Their attempts were completely baffled, and their loſs in men was very conſiderable. The emperor, however, became tributary to the Bulgarians, who ſucceſsfully invaded ſome of his territories. This prince, who died in the year 685, appears to have poſſeſſed a ſmall ſhare of talent, intermixed with cunning and cruelty. On his two brothers he had beſtowed the empty title of Auguſtus, unconnected with truſt or power. At their ſecret inſtigation, the troops of the Anatolian province approached the city on the Aſiatic ſide, demanding for their royal brothers the partition or exerciſe of ſovereignty, and ſupported their claims by a theological argument. "We are Chriſtians," they ſaid, "the ſincere votaries of the holy and undivided Trinity: ſince there are three equal perſons in heaven, there ſhould be three equal perſons on earth." The emperor invited them to a friendly conference, in which they might propoſe their arguments to the ſenate: they obeyed the ſummons; but the view of their bodies, hanging on the gibbet in the ſuburb of Galatea, reconciled their companions to the unity of the reign of Conſtantine. He pardoned his brothers; but on the repetition or ſuſpicion of a ſimilar offence, the obnoxious princes were deprived of their titles and noſes, that the deformity might diſqualify them from the empire. In the cloſe of life, Conſtantine was anxious to eſtabliſh the right of primogeniture; and the eldeſt ſon was exalted to the rank of Auguſtus, and the aſſurance of the empire.

Constantine V., ſon of the emperor Leo, was born in 719, and crowned in his infancy. He was ſurnamed *Copronymus*, from having polluted the baptiſmal font. During a long reign of 34 years, he ever exhibited an abhorrence of image-worſhip, which rendered him an object of hatred to the catholics, who have uſed every means in their power to tranſmit his name to poſterity in the moſt diſguſting light. Although he did not merit all the opprobria affixed to his character by eccleſiaſtical bigots, yet he undoubtedly exerciſed much cruelty towards the party which reſiſted his attempts for reform in the church. Some were put to death, others mutilated, and not a few underwent leſs ſevere puniſhments. As a general, he exhibited much prudence and courage. Soon after his acceſſion he marched againſt the Saracens, who had made an irruption into Aſia; and his brother-in-law, taking advantage of his abſence, placed himſelf at the head of the orthodox faction, and was declared emperor. A civil war enſued, in which Conſtantine was victorious: the metropolis ſurrendered to its lawful ſovereign, and the uſurper and his ſon were deprived of their ill-gotten power, and of their eyes. When every thing at home was ſettled to his ſatisfaction, he made war again upon the Saracens, took their ſtrong places, and deſtroyed their fleet. In the midſt of his ſucceſſes, an earthquake, and a peſtilence among his own people, were calamities which excited in him the greateſt conſternation. After this he was attacked by the Bulgarians, by whom he was ſo completely defeated, that he was obliged to ſeek refuge in his capital: but in another attack, victory determined for Conſtantine, who cut off the invaders, with ſcarcely any loſs. As he was proceeding on a new expedition againſt the ſame people, he was ſeized with a fever, which terminated his life in 775. To the praiſe of this prince, his enemies admit that he reſtored the ancient aqueduct, a work of great importance to the inhabitants of Conſtantinople. He redeemed nearly three thouſand captives: and under his reign, plenty was the characteriſtic of the times. Moreri. Gibbon. Univer. Hiſt.

CONSTANTINE VI., grandſon of the preceding, was born in 770; and when only five years of age, he was aſſociated with his father, Leo IV., in the government: but neither then, nor in 780, when he ſucceeded entirely to the throne, was he capable of efficient buſineſs. His mother Irene was appointed guardian to the young emperor: ſhe, naturally ambitious, and impatient of controul, was unwilling to reſign the power out of her own hands. The conteſts between the mother and her ſon were the moſt prominent features of this reign. During the childiſh years of the emperor, nothing could be better adminiſtered than the government under Irene: but when he had attained the years of maturity, by the advice of his adherents, he would fain have rewarded his mother's ſervices by perpetual baniſhment to the iſle of Sicily. Irene was too politic to be thus ſerved: ſhe retaliated upon her enemies, and obtained for herſelf almoſt an unlimited obedience. Her abuſe of victory proved detrimental to her intereſts: Conſtantine aſcended the throne ſole ſovereign, and his mother was diſmiſſed to a life of ſolitude, to the enjoyment of which her mind was by no means adapted. She was recalled to court, and ſoon obtained a certain degree of authority. The emperor was attacked and defeated by the Bulgarians; and ſuſpecting an inſurrection in favour of Nicephorus, ſon of Conſtantine V. by a ſecond marriage, he had him ſeized and his eyes put out, and the tongues of his four brothers were amputated. After this cruel puniſhment, they were doomed to perpetual impriſonment. For five years they ſubmitted to their fate: an opportunity then offered, and they made their eſcape to the church of St. Sophia, diſplaying a pathetic ſpectacle to the people. "Countrymen and Chriſtians," exclaimed Nicephorus for himſelf and mute brethren, "behold the ſons of your emperor, if you can recognize our features in this miſerable ſtate. A life, an imperfect life, is all that is ſpared: this is now threatened, and we appeal to your compaſſion." Their wretchedneſs affected the people, but the miniſter of Conſtantine contrived to ſoothe their miſeries, and draw them from public view. They were ſpeedily embarked for Greece, and Athens allotted to them as a place of exile. Once more they eſcaped from the hands of their keepers, and appeared in purple at the gates of Conſtantinople. This was their laſt effort: in attempting to gain a crown, they loſt their lives. Irene ſoon found an opportunity of exciting diſcontents, with a view of depoſing her ſon. Suſpecting his danger, he attempted to eſcape to the provinces, but was ſeized on the Aſiatic ſhores, and carried priſoner to his own palace, where, in the very chamber in which he was born, the emiſſaries of his unnatural and infamous mother aſſaulted him in his ſleep, and plunged their daggers in his eyes. In this ſtate he ſurvived many years, to reflect on his own cruelty, and to learn the uſurpations of Irene.

CONSTANTINE VII. was ſon of the emperor Leo VI., and nephew to Alexander, whom he ſucceeded in 912, being but ſeven years of age. During his minority, Romanus Lecapenus, a ſucceſsful general, got poſſeſſion of the emperor's perſon, and perſuaded him to marry his daughter. He then aſſumed the royal purple himſelf, and aſſociated his own three ſons in the imperial authority, degrading the lawful emperor to the fifth rank among the titular princes. Much, however, to the honour of Romanus, he permitted him to live unmoleſted; and the time of Conſtantine was ſpent in the ſtudy and practice of the fine arts. The fall of Romanus was occaſioned by the ambition of his own children, who effected the baniſhment of their father, and, contrary to their own expectations, elevated Conſtantine to his rightful throne. To prevent their future intrigues, the emperor's firſt act was to ſeize the conſpirators, and baniſh them to the ſame iſland and monaſtery in which they had ſo lately confined their father. Romanus met them on the beach with a ſarcaſtic ſmile, and, after a juſt reproach of their folly, ingratitude, and weakneſs, preſented his imperial colleagues with an equal ſhare of his water and vegetable diet. Conſtantine was now in poſſeſſion of the eaſtern world, which he governed, or appeared to govern, fifteen years. He was, however, devoid of that energy of character which became the ſovereign of ſo mighty an empire. The ſtudies which had amuſed his life of comparative ſolitude, were not eaſily exchanged for the ſerious and important duties of a monarch. The reins of government he entruſted to his wife Helena, while he employed much of his time in the inſtruction of his ſon Romanus, and in drawing up a treatiſe for his immediate benefit, but of which he made ſo ill a uſe, that he is ſuſpected of having adminiſtered poiſon to his father, in order to ſucceed him in the empire. The death of Conſtantine was regretted by his ſubjects, who paid every demonſtration of reſpect to his deceaſed corpſe, which, according to uſual cuſtom, lay in ſtate at the palace. Before the proceſſion moved to the ſepulchre, an herald proclaimed the awful admonition: "Ariſe, O king of the world, and obey the ſummons of the King of kings."—One of the depoſed ſons of Romanus had, during his ſhort-lived authority, aſſumed the title of CONSTANTINE VIII.: of him therefore enough has been ſaid;—and we proceed to the reign of CONSTANTINE IX., who, in conjunction with his brother, Baſil II., ſucceeded to the throne, on the death of John Zimiſces, in the year 976. During the long life of Baſil, Conſtantine had only the name of emperor: all emanated from his brother. After his deceaſe, Conſtantine enjoyed, about three years, the power, or rather the pleaſures, of royalty; and his chief care was the ſettlement of the ſucceſſion. He had poſſeſſed, ſixty-ſix years, the title of Auguſtus; and the reign of the two brothers is the longeſt and moſt obſcure of the Byzantine hiſtory. He ended his inglorious life in 1028, at the age of ſeventy.

CONSTANTINE X. was ſurnamed *Monomachus*, the ſingle combatant, which was probably expreſſive of his valour and victory in ſome public or private quarrel. He was a Greek of noble extraction, and recalled from exile in Leſbos to ſucceed Michael V. He was at that time married to Zoe, the daughter of Conſtantine IX. With her, who had already been wife to two emperors, he was diſſatisfied, and took, as concubine, a widow, to whom he gave the title of Auguſta. This reign was diſturbed by various revolts, in which the emperor was uſually victorious. He was ſucceſsful alſo againſt his foreign enemies; but his indolence or avarice gave the Turks an opportunity of gaining a footing in Aſia Minor. He died in 1054. The health of this emperor had, during the greater part of his life, been broken by the tortures of the gout, and his reign was ſpent in the alternatives of ſickneſs and pleaſure.

CONSTANTINE XI. ſurnamed *Ducas*, was choſen by the emperor Iſaac Comnenus, as the fitteſt perſon to ſucceed him, when he voluntarily laid down the crown in 1059. The beginning of his reign was afflicted by a conſpiracy of his own people againſt him. Having quelled this, he began to turn his attention to government, for which he ſeems to have been very unequal. By the principles of avarice, he neglected the maintenance of his garriſons on the frontiers, and the Uxians, a people of Scythia, taking advantage of this circumſtance, paſſed the Danube, and laid waſte the country. They penetrated into Greece, and defeated the imperial generals, who had been ſent againſt them. Conſtantine would have gladly purchaſed peace, on any terms; they, however, diſdained to treat, and were finally ſtopped in their victorious career, by peſtilence, and the arms of the Bulgarians, circumſtances which deſtroyed the greater part of the number, that in the outſet amounted to nearly half a million of ſouls. During this reign an earthquake did much damage to the empire. Conſtantine died at the age of 60 years, having previouſly ſecured the ſucceſſion of his three ſons. Of theſe one aſſumed the title of CONSTANTINE XII.; but his glory was merely nominal, and loſt in that of his elder brother Michael. Of the eleventh CONSTANTINE, hiſtorians ſay he was an orthodox and juſt prince, but the ſlave of avarice. The XIIIth prince of this name was ſon of the emperor Manuel Palæologus, and ſucceeded his brother John in 1448, at a period when the whole empire ſcarcely extended beyond the limits of the capital. This ſovereign having ſquandered the ſmall remaining reſources of his dominion in imperial oſtentation, found himſelf threatened with the hoſtility of his potent neighbour, ſultan Mahomet II., who erected a fortreſs on the Boſphorus, found occaſion for a quarrel, and laid ſiege to the capital. Conſtantine determined to reſiſt to the laſt, and to ſhare the fate of his people. He ſought for ſuccour among the Chriſtian princes of the Weſt, but the aid he obtained was tardy, and inſufficient to the greatneſs of the occaſion. Conſtantinople was encompaſſed by Turkiſh arms, and the emperor, in this extremity, fulfilled the part of a hero. When the final aſſault was prepared, he took leave of his people in a moving harangue, received the ſacrament in the church of St. Sophia, and then went to the walls. The numbers of the Turks without, exceeded thoſe of the Chriſtians within, the city, more than a hundred fold. Every hope of ſucceſsful reſiſtance was vaniſhed; breaches had been made in the walls, and at length they and the towers were covered with ſwarms of the aſſailants. Amidſt theſe multitudes, the emperor, who nobly accompliſhed all the duties of a general and ſoldier, was long ſeen, and finally loſt; his mournful exclamation was heard, "Cannot there be found a Chriſtian to cut off my head?" His laſt fear was that of falling alive into the hands of the infidels. He had thrown off the purple, and falling by an unknown hand, was buried under a mountain of ſlain. The final cataſtrophe of the Greek empire, and emperor, happened May 29th, 1453, Conſtantinople having ſuſtained a ſiege of 58 days. See CONSTANTINOPLE. Moreri. Gibbon. Univer. Hiſt.

CONSTANTINE, FLAVIUS JULIUS, from a private ſoldier, in the legions of Britain, was raiſed to imperial honours, on account of his name, and in reſpect for the great Conſtantine. He had no ſooner attained the high honour, than he paſſed over to Gaul with his troops, and made himſelf maſter of that country. With the aſſiſtance of his ſon Conſtans, he reduced Spain; and upon Conſtans he conferred the title of Auguſtus. Conſtantine fixed his throne at Arles, and when the Goths under Alaric had taken poſſeſſion of Italy, he marched as far as the Po, on the pretence of effecting its deliverance, but probably with a view of ſharing in the ſpoil. After paſſing through various ſcenes, in which he experienced by turns ſucceſs and diſaſter, Conſtantine was beſieged in his capital by Conſtantius, to whom he ſurrendered, on the promiſe of ſecurity for himſelf and his ſon. The terms were granted, but the engagement was not fulfilled. The fallen prince was ſent to Italy, where he and his ſon Julian, in violation of a ſolemn promiſe, ſuffered death by the emperor's orders, Sept. the 18th, 411. Moreri. Gibbon.

CONSTANTINE: there were two popes of this name: the one a native of Syria, raiſed to the Roman ſee in 708, characterized for his charity to the poor; and for his ambition, in engaging Juſtinian to ſubjugate the independent ſee of Ravenna to the yoke of Rome; the other, from a layman, was raiſed to the higheſt office in the church by the influence of his brother; an honour, however, that he did not long retain. An inſurrection being excited againſt him, in about a year after his elevation, he was depoſed, and, under the reign of the new pope, was ſubject to the inſults and moſt cruel treatment of the people, deprived of his ſight, and condemned to perpetual impriſonment. Moreri.

CONSTANTINE is the name likewiſe of an abbot who flouriſhed at Metz in the eleventh century, and who was author of "The Life of Adalberon II." biſhop of that city: and of a monk diſtinguiſhed for his writings in the thirteenth century, againſt Veccus, patriarch of Conſtantinople. Another of the ſame name was born at Florence, and became biſhop of Orvieto. He acquired celebrity by his preaching talents, and after his elevation to the biſhopric, he was appointed legate from pope Alexander IV. to Theodore Laſcaris, the Grecian emperor, hoping, by his perſuaſion, to induce the emperor and his clergy to ſubmit to the Roman ſee. He was author of the life of St. Dominic, and other works. He died in the year 1257.

CONSTANTINE, ſurnamed the *African*, was born at Carthage, about the middle of the eleventh century. He reſided many years in Babylon, where he became celebrated for his knowledge in the Arabian, Chaldean, Perſian, and Ægyptian languages. Among the ſciences, medicine ſeems to have received the greateſt ſhare of his attention, as appears by two of his works, which were thought deſerving of being printed ſeveral centuries after his death. In the firſt, which was publiſhed at Bale, in the year 1536, in folio, "De morborum cognitione, et curatione," libri ſeptem, he treats of affections of the ſtomach, hypochondriaſis, on the diſeaſes of women, &c. In the ſecond, which was alſo publiſhed at Bale, three years after the former, he treats of fevers, of the elephantiaſis, of incantations, and of remedies taken from parts of animals. The whole are however ſuppoſed to have been principally tranſlated from Arabian writers. After a reſidence of thirty nine years at Babylon, he returned to Carthage, but ſoon fell into ſuch diſgrace with his countrymen, whom he ſuſpected of intending to deſtroy him, that he went to Salernum. Though he was there introduced to duke Robert, who wiſhed to retain him about his perſon, preferring a life of eaſe and retirement, he entered into a monaſtery of the Benedictines, St. Agatha, in Averſa, where he died in 1087. Haller Bib. Med. Eloy Dict. Hiſt.

CONSTANTINE, ROBERT, a native of Caen in Normandy, was born, as it is ſaid, about the year 1502. He was profoundly verſed in Greek, Latin, and oriental literature. This procured him the intimacy of J. Cæſar Scaliger (with whom he reſided ſeveral years), and of other great ſcholars, but did not defend him againſt the ſarcaſms of Joſeph Scaliger, who attacked him with great ferocity. He took his degree of doctor in medicine, but from the many learned works he publiſhed, does not ſeem to have dedicated much of his time to the practice of that art. His editions, with annotations, of the works of Theophraſtus, Dioſcorides, Celſus, and Quintus Serenus, gained him much credit. They were publiſhed between the years 1554 and 1566, as was alſo his "Nomenclator inſignium Scriptorum, quorum libri extant vel manuſcripti, vel impreſſi," 8vo. But the work which eſtabliſhed his name as a ſcholar, was his "Lexicon Græco-Latinum," firſt publiſhed at Geneva, in 1562, in two volumes folio; reprinted, much improved, in 1592. He is ſaid by De Thou to have lived to the great age of 103 years, preſerving his faculties entire to the laſt. Other writers ſay he died of a pleuriſy at the age of 75 years. Haller. Bib. Bot. Eloy Dict. Hiſt.

CONSTANTINE, ANTONY, an eminent phyſician at Lyons, publiſhed in 1597, in 8vo. "Brief traité de la Pharmacie Provençale, et familiere," in which he attempts to ſhew his countrymen, that they may find in their fields remedies for their diſeaſes, without having recourſe to drugs imported from foreign countries. Alſo "Opus Medicæ prognoſeos, in quo omnium ſymtomatum, cauſæ et eventus exponuntur." 8vo. 1613. He died, far advanced in years, in 1616. Eloy Dict. Hiſt.

CONSTANTINE, *Order of*, in *Heraldry*, otherwiſe the order of the Golden Angel and St. George. Conſtantine the Great is by ſome conſidered as the founder of this order, after his memorable victory over the tyrant Maxentius, A. C. 312. This is at preſent the ſecond order of the kingdom of Naples. Others affirm that the emperor Iſaac Angelus Comnenus was the founder of it. The badge of the order is a red croſs, ſomewhat in the form of four fleurs-de-lis joined at the extremities, ſurrounded with a border of gold, thereon embroidered the four letters I. H. S. V.; meaning, "In hoc ſigno vinces," being the words diſplayed on the celeſtial meteor, or luminous croſs, which is ſaid to have appeared to Conſtantine, and encouraged him to attack Maxentius. In the centre of the badge is a monogram, or cypher of our Saviour's name, expreſſed by the letters X and P, and on each ſide are placed one of the letters A and Ω (alpha and omega, or the firſt and the laſt letters of the Greek alphabet.)

The great collar of this order, worn over the mantle, conſiſts of fifteen enamelled golden ſhields of an oval form, and on each the letters X and P appear in the form of a cypher. The middle ſhield is ſomewhat larger than the others, and is ſurrounded with oak and laurel leaves entwined; and from the lower part of it is ſuſpended the effigy of St. George, in compleat armour, on horſeback, and in the act of ſtriking the dragon.

The council of this order is compoſed of 50 ſenators, who are grand croſſes. When the grand maſter aſſiſts in ſtate therein, his dreſs is as follows: the veſt and ſmall cloaths are of imperial ſcarlet, as alſo the ſtockings and ſhoes; above the veſt is worn a caſſock of ſilver, richly embroidered, with wide ſleeves, and reaching to the knees, faſtened round the waiſt with a girdle of ſcarlet velvet, embroidered with ſilver, and about the neck with two rich cords of gold and ſcarlet ſilk mixed, with taſſels reaching to the ground. On the left ſide of the mantle, the croſs of the order is richly embroidered in gold. The cap is of crimſon velvet, and is one ſpan high, lined with white ſatin, and adorned with a black oſtrich feather. The four ſides are turned up, and on each the cypher of our Saviour, as above deſcribed.

The grand croſſes (in number 50) wear a blue veſt and ſmall cloaths, and over the ſame a white veſt, which reaches to the knees; their ſtockings and ſhoes are white; their girdle red, and their mantle of blue damaſk is lined with white: they wear the great collar of the order, and their cap, which is of blue ſatin, is turned up at the four ſides, and on each the cypher as before: the cap is alſo adorned with a white oſtrich feather.

The popes had conferred the grand maſterſhip on the houſe of Comnenus for ever; but in 1699 Angelus Flavius Comnenus, the laſt of this houſe, reſigned it to Francis Farneſe, the then duke of Parma, to him and his ſucceſſors for ever; which was confirmed by a brief of pope Innocent XII. dated 29th October, 1699. In 1735 the ducal houſe of Farneſe becoming extinct in the male line by the death of Anthony the laſt duke, Don Carlos, the eldeſt ſon of Philip V. king of Spain, and of Elizabeth Farneſe, the ſole heireſs of the family, ſucceeded to the duchies of Parma and Placentia, and to the grand maſterſhip of this order. This prince was ſucceſſively grand duke of Tuſcany, and king of Naples: upon his ſucceſſion to the latter he declared this order royal, and annexed it to the crown of Naples.

CONSTANTINOPLE, in *Geography*, the metropolis of the Turkiſh empire, was built on the ſcite and ruins of the ancient *Byzantium* in Thrace, by the Roman emperor Conſtantine the Great, who, in the year of our Lord 330, removed the ſeat of the empire from Rome to this new capital. The reaſons which induced Conſtantine to fix his reſidence here, are not exactly known. The imperial court had in fact been removed from Rome about thirty years before. Of the aſſociate emperors Diocletian and Maximian, the former reſided at Nicomedia, and the latter moſtly at Milan. Galerius had his court at Nicomedia; Conſtantius Chlorus at York. It is ſuppoſed that Diocletian and Maximian, having concerted a plan of adminiſtration more ſyſtematically deſpotic than that of any of the preceding emperors, and being deſirous of ſetting entirely aſide the nominal authority which the ſenate ſtill poſſeſſed, had fixed their reſidence at a diſtance from the ancient metropolis of the empire, in order to avoid the republican remonſtrances of that auguſt body. Conſtantine was probably actuated by the ſame motive, for his adminiſtration was ſtill more deſpotic; and after he had removed the ſeat of empire to Conſtantinople, the ſenate could ſcarcely be reckoned a conſtituted order in the ſtate. Others attribute Conſtantine's choice of a new capital to a diſlike which he had conceived againſt Rome, on account of the enthuſiaſtic attachment of that city to paganiſm. But whatever may have been Conſtantine's motive, it cannot be denied that the ſituation of Conſtantinople actually was preferable to that of Rome, both as a check to the Perſians, and as a barrier againſt the Goths, thoſe terrible enemies of Rome, who, having once taſted the rich plunder of Greece and Aſia Minor, ſeized every opportunity of making predatory incurſions into all parts of the empire. Beſides, the beautiful and pictureſque arrangement of the land and water in the environs of Conſtantinople decidedly entitled it to be preferred to Rome. It is ſituated on an elevated ground, conſiſting of gently ſwelling eminences, riſing like terraces, one above another, without any of thoſe deep vallies which ſeparate the ſeven hills on which Rome is ſeated, and which, together with the marſhes adjoining the Tyber, render the air unwholeſome. It fills a triangle formed by the harbour, the BOSPHORUS and the PROPONTIS, or ſea of MARMORA. Situated in the 41ſt degree of latitude, the imperial city commanded, from her ſeven hills, the oppoſite ſhores of Europe and Aſia; the climate was healthy and temperate, and the ſoil fertile, and the approach on the ſide of the continent was ſmall in extent, and eaſy of defence. The harbour on the north ſide is ſecure and capacious; it is five hundred yards wide at its entrance from the Boſphorus, and runs ſeven miles into the land. The Boſphorus and the Helleſpont may be conſidered as the two gates of Conſtantinople; and the prince who poſſeſſed thoſe important paſſages could always ſhut them againſt a naval enemy, and open them to the fleets of commerce when thoſe gates were ſhut. The capital ſtill enjoyed within their ſpacious encloſure every production which could ſupply the wants, or gratify the luxury, of its numerous inhabitants. In ſailing up the Propontis towards Conſtantinople the moſt enchanting proſpects charm the eye of the navigator; from every part of that ſea he may diſcover the high lands of either Thrace or Bithynia, and never loſes ſight of mount Olympus, till at laſt the city itſelf, riſing from the Strand, attracts his view, and exhibits the moſt magnificent appearance. Conſtantinople alſo commands the commerce of the vaſt regions of the north, by means of the Euxine ſea, and of the rivers Don and Dnieper, which diſcharge themſelves into it. By the ſtrait of the Helleſpont, which forms the communication between the Propontis and the Mediterranean ſea, it is equally well ſituated for the trade of the ſouth and weſt; and when Egypt is under its dominion its poſition is extremely advantageous with reſpect to the trade to India, and the eaſtern coaſts of Africa.

Whatever rude commodities were collected in the foreſts of Germany and Scythia, as far as the ſources of the Tanais and Boryſthenes; whatſoever was manufactured by the ſkill of Europe or Aſia; the corn of Egypt, and the gems and ſpices of the fartheſt India, were brought by the varying winds into the ports of Conſtantinople, which for many ages attracted the commerce of the ancient world.

The proſpect of beauty, of ſafety, and of wealth, united in a ſingle ſpot, was ſufficient to juſtify the choice of Conſtantine. However, as prodigy and fable have, in every age, been ſuppoſed to reflect a becoming majeſty on the origin of great cities, the emperor thought proper to avail himſelf of this circumſtance; and in one of his laws he has taken care to inform poſterity, that in obedience to the commands of God, he laid the everlaſting foundation of Conſtantinople. The ingenuity of ſucceeding writers has led them to deſcribe the nocturnal viſion which appeared to the fancy of Conſtantine as he ſlept within the walls of Byzantium. The tutelar genius of the city, a venerable matron, ſinking under the weight of years and infirmities, was ſuddenly tranſformed into a blooming maid, whom his own hands adorned with all the ſymbols of imperial greatneſs. The monarch awoke, interpreted the auſpicious omen, and, without heſitation, obeyed the will of heaven. In order deeply to impreſs the minds of the ſpectators, the emperor himſelf, on foot, with a lance in his hand, led a ſolemn proceſſion, and directed the line, which was traced as the boundary of the deſtined capital, till the growing circumference was obſerved with aſtoniſhment by the aſſiſtants, who, at length, ventured to obſerve that he had already exceeded the moſt ample meaſure of a great city. "I ſhall ſtill advance," replied Conſtantine, "till HE, the inviſible guide who marches before me, thinks proper to ſtop." In ſurveying the actual ſtate of the city, the palace and gardens of the ſeraglio occupy the eaſtern promontory, the firſt of the ſeven hills, and cover about 150 acres of our meaſure. The new walls of Conſtantine ſtretched from the port to the Propontis acroſs the enlarged breadth of the triangle, at the diſtance of fifteen ſtadia from the ancient fortification; and with the city of Byzantium they encloſed five of the ſeven hills, which, to the eyes of thoſe who approach Conſtantinople, appear to riſe above each other in beautiful order. About a century after the death of the founder, the new buildings, extending on one ſide up the harbour, and on the other along the Propontis, already covered the narrow ridge of the ſixth, and the broad ſummit of the ſeventh hill. The inceſſant inroads of the Barbarians rendered it neceſſary for Theodoſius the younger to ſurround his capital with an adequate and permanent encloſure of walls. The new wall of Theodoſius was conſtructed in the year 413; and after having been thrown down by an earthquake in 447, it was rebuilt in three months by the diligence of the prefect Cyrus. The ſuburb of the Blachernæ was firſt taken into the city in the reign of Heraclius. From the eaſtern promontory to the golden gate, the extreme length of Conſtantinople was about three Roman miles; the circumference meaſured between ten and eleven; and the ſurface might be computed as equal to about 2000 Engliſh acres. The ſuburbs of Pera and Galata, though ſituate beyond the harbour, may deſerve to be conſidered as a part of the city; and this addition may perhaps authorize the meaſure of a Byzantine hiſtorian, who aſſigns ſixteen Greek (about fourteen Roman) miles for the circumference of his native city. After all, Conſtantinople muſt yield to Babylon and Thebes, which filled the great but not incredible circumference of about 25 or 30 miles, to ancient Rome, to London, and even to Paris.

As to the expence incurred by the progreſs of the work, ſome eſtimate may be formed of it by the allowance of about two millions five hundred thouſand pounds for the conſtruction of the walls, the porticoes, and the aqueducts. The foreſts that overſhadowed the ſhores of the Euxine, and the celebrated quarries of white marble, in the little iſland of Proconneſus, ſupplied an inexhauſtible ſtock of materials ready to be conveyed, by the convenience of a ſhort water-carriage, to the harbour of Byzantium. A multitude of labourers and artificers urged the termination of the work with inceſſant toil; but the impatience of Conſtantine ſoon diſcovered that, in the decline of the arts, the ſkill, as well as the number of his architects, bore a very unequal proportion to the greatneſs of his deſign. However, the buildings of the new city were decorated by the hands of the moſt celebrated maſters of the age of Pericles and Alexander. By the commands of the emperor, the cities of Greece and Aſia were deſpoiled of their moſt valuable ornaments. The trophies of memorable wars, the objects of religious veneration, the moſt finiſhed ſtatues of the gods and heroes, of the ſages and poets of ancient times, contributed to the ſplendid triumph of Conſtantinople; whence the hiſtorian Cedrenus took occaſion to obſerve, that nothing ſeemed wanting except the ſouls of the illuſtrious men, whom thoſe admirable monuments were intended to repreſent. For an account of the principal buildings with which this imperial city was decorated, we muſt refer to the articles Forum, Hippodrome, &c. and the ſequel of this article.

The baths of this city, which ſtill retained the name of Zeuxippus, were enriched by the munificence of Conſtantine with lofty columns, various marbles, and above threeſcore ſtatues of bronze. In ſhort, whatever could adorn the dignity of a great capital, or contribute to the benefit or pleaſure of its numerous inhabitants, was contained within the walls of Conſtantinople. A particular deſcription, compoſed about a century after its foundation, enumerates a capitol or ſchool of learning, a circus, two theatres, eight public, and 153 private baths, 52 porticoes, five granaries, eight aqueducts or reſervoirs of water, four ſpacious halls for the meetings of the ſenate or courts of juſtice, 14 churches, 14 palaces, and 4388 houſes, which, for their ſize and beauty, deſerved to be diſtinguiſhed from the multitude of Plebeian habitations. In order to furniſh this favoured city with a population, correſponding to its extent and magnificence, Conſtantine invited many opulent ſenators of Rome, and of the eaſtern provinces, to fix upon his choſen reſidence for their own habitation; and he beſtowed on his favourites the palaces which he had built in ſeveral quarters of the city, aſſigned them lands and penſions for the ſupport of their dignity, and alienated the demeſnes of Pontus and Aſia, for the purpoſe of granting hereditary eſtates by the eaſy tenure of maintaining a houſe in the capital. By degrees, however, a variety of concurring circumſtances contributed to fill the city with inhabitants. In leſs than a century, Conſtantinople diſputed with Rome itſelf the pre-eminence of riches and numbers; and it became neceſſary to enlarge its extent by additional edifices, the foundations of which, on either ſide, were advanced into the ſea, and which, of themſelves, might have compoſed a very conſiderable city. The emperor alſo conferred, by way of additional allurement or encouragement to his plan of population, ſeveral privileges on the ſettlers at Conſtantinople. He divided the city into fourteen regions or quarters, dignified the public council with the appellation of ſenate, communicated to the citizens the privileges of Italy, and beſtowed on the riſing city the title of colony, the firſt and moſt favoured daughter of ancient Rome. The walls, porticoes, and principal edifices of this city, were completed, as ſome ſay, in a few years, or, according to others, in a few months; and the founder ſoon prepared to celebrate the dedication of his city, a ceremony which was attended with pompous games, and munificent largeſſes. As often as the birth day of the city returned, the ſtatue of Conſtantine, framed by his order, of gilt wood, and bearing in its right hand a ſmall image of the genius of the place, was enriched on a triumphal car. The guards, carrying white tapers, and clothed in their richeſt apparel, accompanied the ſolemn proceſſion as it moved through the Hippodrome. When it was oppoſite to the throne of the reigning emperor, he roſe from his ſeat, and with grateful reverence adored the memory of his predeceſſor. At the feſtival of dedication, an edict, engraved on a column of marble, beſtowed the title of Second, or New Rome, on the city of Conſtantine. But the name of Conſtantinople has prevailed over that honourable epithet, and, after the revolution of fourteen centuries, ſtill perpetuates the fame of its author.

It has been conjectured, that the removal of the imperial reſidence from Rome, contributed to haſten the downfal of the empire: but it is certain, that the fixing of it at Conſtantinople, put a final period to the paſſage of the Barbarians, through the Boſphorus. They could never after force that inſurmountable barrier, and Greece, as well as Aſia Minor, felt ſecure from their ravages, until Valens unadviſedly ſuffered the Goths to paſs the Danube, and received their armed bands into the heart of the empire.

Conſtantine the Great did not long enjoy his new reſidence. He died the 22d May, 337, and by his will divided his vaſt empire among his three ſons, Conſtantius, Conſtans, and Conſtantine. Within three years after their father's death, Conſtans invaded the dominions of his brother Conſtantine, who, being drawn into an ambuſcade and ſlain, left Conſtans in poſſeſſion of two-thirds of the Roman empire. But Magnentius revolting ſoon after againſt Conſtans, ſurpriſed him hunting, and purſuing him in his flight, put him to death. Magnentius being in the next place defeated by Conſtantius, terminated his life by ſuicide; and thus, by the diſaſtrous fate of his brothers, Conſtantius became ſole emperor in 353; three and twenty years after the ſeat of the empire had been removed to Conſtantinople.

At the death of Conſtantius, which happened in the year 361, Julian, commonly called the Apoſtate, ſon of Julius Conſtantius, and nephew to Conſtantine the Great, aſſumed the imperial purple. He marched ſoon after againſt the Perſians, and was ſo infatuated by his expectations of conqueſt, as to deſtroy the fleet of boats which he had upon the Tigris. Allured by ſpies who pretended to be deſerters, he advanced far into an unknown country. His army found itſelf at laſt in the midſt of ſandy deſerts, and felt the dreadful effects of famine. The guides ſuddenly diſappeared, and the Perſian monarch approaching, with the whole military force of his kingdom, want of proviſions rendered a retreat neceſſary, in which the troops were continually haraſſed by the Perſians, who carefully avoided any cloſe engagement. In ſpite of the inceſſant attacks of the Perſian cavalry, the Romans ſucceeded in gaining the banks of the Tigris, but for want of their boats they could not paſs the river. Exhauſted with fatigue, and periſhing with hunger, they ſtill repulſed the attack which the Perſian king made on their camp. In the confuſion of the battle, Julian received a mortal wound, of which he died in a few hours, on the 26th of June, 363.

This emperor had conceived the project of extirpating the Chriſtian religion; and if he had appointed, or if the army had elected an emperor equally averſe to Chriſtianity, his death would not have diſpelled the ſtorm that was gathering over Chriſtendom. Fortunately, Jovian, a Chriſtian officer, was choſen emperor. Forced to conclude a diſadvantageous peace with Perſia, he purchaſed a ſafe retreat by the ceſſion of Meſopotamia, and the ſtrong cities of Niſibis and Singara.

Jovian dying in 364, ſoon after the concluſion of the peace with Perſia, Valentinian, another Chriſtian commander, was decorated with the imperial purple. He named his brother Valens his colleague in the empire, aſſigning him the eaſtern part, whilſt he himſelf ruled the weſt. It was in this reign that the firſt ſtep towards the ſubverſion of the weſtern empire took place. The Huns, a Tartar nation, being driven out of their own country, ruſhed like a torrent upon the Goths, on the north ſide of the Danube, who, ſeeing their poſſeſſions invaded, preſented themſelves in immenſe crowds on the banks of the river, and requeſted an aſylum in the Roman dominions. They delivered up their children, at leaſt thoſe of rank, as hoſtages; but were unfortunately ſuffered to retain their arms. The number of Goths who paſſed the Danube on the occaſion, was computed at about 200,000 armed men, with their wives and children along with them. A ſecond army of Goths, coming to the banks of the Danube with the ſame requeſt, was refuſed: but they paſſed without leave, and being ill ſupplied with proviſions, they joined their countrymen, and commenced a war againſt the empire. After various ſkirmiſhes, Valens, without waiting for his nephew Gratian, who was on his march to join him, gave battle to the Goths, in the plains of Adrianople, A. D. 378, and was totally defeated. The loſs on the ſide of the Romans was ſo great, that this defeat was conſidered as the moſt ſevere ſince the battle of Cannæ. Valens was never more ſeen. It is ſuppoſed that he was conſumed in the flames of a cottage where he had taken refuge.

By the death of Valens, the empire fell into the hands of his nephew Gratian, who had ſome time before ſucceeded to Valentinian in the weſt. But at the end of the year 378, he declared Theodoſius his partner in the empire, and committed the Eaſt to his care.

Theodoſius was a native of Spain. In four years and a half he terminated the Gothic war. The Goths had lands aſſigned to them in the Roman provinces, and ſubmitted to the Roman ſceptre on condition of being governed by their own laws.

Theodoſius was in every reſpect a ſecond Conſtantine the Great. Like him he rendered the empire triumphant over all its enemies, extinguiſhed inteſtine commotions, eſtabliſhed Chriſtianity upon a ſolid baſis, and divided the empire between his two ſons Arcadius and Honorius, aſſigning to the former the eaſtern, and to the latter the weſtern part. From that period, the two monarchies, forming two ſeparate and independent ſtates, gradually became ſtrangers to each other, and even regarded each other's proſperity with a jealous eye. Rome fell a prey to the Goths, whilſt Conſtantinople appeared totally unconcerned at the event. Theodoſius died at Milan, the 17th of January 395, in the ſixteenth year of his reign, and the fiftieth of his age.

After the death of Theodoſius, the hiſtory of Conſtantinople affords nothing remarkable, until the total deſtruction of the Roman empire in the weſt by the Goths. Towards that time Baſiliſcus uſurped the Eaſtern empire. Aſſiſted in his conſpiracy by the empreſs Verina, his ſiſter, he drove out Zeno, the lawful emperor, who fled into Iſauria, whither he was purſued by Ilus and Trecondes, two of the uſurper's generals, and forced to ſhut himſelf up in a caſtle. But Baſiliſcus having loſt his popularity by his cruelty, his generals joined Zeno and reſtored him to the throne. Baſiliſcus periſhed in a dungeon in the year 467. He had reigned about twenty months. During his uſurpation, a dreadful fire happened at Conſtantinople; together with a conſiderable part of the city, it conſumed the imperial library which is ſuppoſed to have contained 120,000 volumes.

Zeno had the good fortune to eſcape other conſpiracies that were formed againſt him: but he was unſucceſsful in the wars which he waged againſt the Oſtrogoths, and purchaſed a ſhort peace at the expence of the provinces of Lower Dacia and Mœſia. Theodoric, king of the Oſtrogoths, ſoon renewed his irruptions into Thrace, and advanced within fifteen miles of Conſtantinople, which he was expected to beſiege, when he ſuddenly turned his arms againſt Odoacer, king of Italy, whom he ſubdued. Theodoric himſelf was proclaimed king of Italy in his room, two years after the death of Zeno, which happened in 491.

The adminiſtration of Athanaſius, Zeno's ſucceſſor, was equally weak. Theodoric, however, reigned in Italy under the ſanction of the imperial court of Conſtantinople, and ſtill acknowledged himſelf a vaſſal of the eaſtern emperor. But on his death the kingdom of Italy devolved upon his beautiful and accompliſhed daughter, Amalaſontha; and at her demiſe, which happened in the year 535, the Goths of Italy refuſed to acknowledge the paramount authority of the imperial court, and renounced all dependence on the empire. Juſtinian was then reigning at Conſtantinople. His uncle Juſtin, who aſcended the throne in 518, after Athanaſius, had named him his colleague in the year 527, and dying ſoon after, had left him ſole maſter of the empire. He firſt turned his whole force againſt Choſroes, king of Perſia, diſpatched his general Beliſarius againſt him, and after a ſevere defeat, forced him to ſue for peace.

About this time, a great tumult happened at Conſtantinople. It began among the different factions in the circus. Hypatius, nephew to Athanaſius, was proclaimed emperor. To cruſh this ſedition, Juſtinian ſacrificed two of his miniſters who were moſt obnoxious to the people; but the multitude grew the more outrageous, and ſeveral ſenators having joined the rebels, the emperor felt ſo much alarmed that he thought of abandoning the city, and making his eſcape by ſea. Encouraged, however, by his empreſs Theodora, he reſolved to defend himſelf to the laſt with the few ſenators who had not yet abandoned him. In the mean time, Hypatius was carried in triumph to the circus, where he was beholding the ſports from the imperial throne, among the acclamations of the populace, when Beliſarius on his return from Perſia entered the city with a conſiderable body of troops. He immediately marched to the circus, fell ſword in hand upon the diſarmed multitude, and took Hypatius the uſurper, and Pompey, another of the nephews of Athanaſius, priſoners. They were both beheaded, and their eſtates, as well as thoſe of the ſenators who had joined them, confiſcated.

Juſtinian now turned his arms againſt the Vandals in Africa, and the Goths in Italy. Beliſarius entered Rome A. D. 536, where he was beſieged by the Goths. His gallant defence, with only five thouſand veterans, againſt a numerous army of Goths, commanded by Vitiges their king, during the ſpace of a whole year, is deemed one of the moſt ſignal military exploits recorded in hiſtory. He made many ſucceſsful ſallies. In one ſingle aſſault the Goths are reported to have loſt 30,000 men. They were obliged to raiſe the ſiege on the arrival of freſh troops from Conſtantinople. At length the Gothic kingdom of Italy was completely ſubdued. Vitiges the king was ſent to Conſtantinople. Juſtinian aſſigned him for maintenance a rich eſtate in Aſia Minor, and on his conforming to the Athanaſian creed, conferred upon him the rank of Patrician and Senator, which ſtill continued as an honorary title in the empire. Gelimer, king of the Vandals, over whom Juſtinian alſo triumphed, had likewiſe an ample eſtate aſſigned to him, but could not enjoy any honorary title on account of his profeſſing Arianiſm.

In the year 546, the Goths again revolted under the command of Totila, whom they had elected king. Beliſarius a ſecond time entered Italy, and retook Rome in 547, but at his recal it was again captured by the Goths. The command of the army of Italy was then conferred on Narſes, an eunuch of great military ſkill and the moſt daring courage. This general defeated and ſlew Totila the Gothic king, and made himſelf maſter of Rome in 552. He likewiſe defeated and ſlew Teias, who had ſucceeded Totila as king of the Goths, and made a prodigious ſlaughter of the Franks and Allemanni, who invaded Italy ſoon after. Italy was then made a province of the eaſtern or Byzantine empire, and a government eſtabliſhed under the denomination of the Exarchate, of which Narſes was the firſt exarch.

By the conqueſt of Italy and Africa, Juſtinian gave to the eaſtern empire an aggrandizement which it had never before poſſeſſed. He diſplayed conſummate political abilities, during a reign of thirty-eight years, and exhibited, during a life of eighty-three, a ſingular inſtance of long continued perſonal proſperity. He has left a noble monument of his legiſlative talents in his code of laws, and a no leſs noble one of his ſkill in architecture, in the magnificent cathedral of St. Sophia at Conſtantinople, now a Mahometan moſque. His reign is alſo the important æra of the tranſplantation of the ſilk-worm from China to Conſtantinople. The brilliancy of Juſtinian's reign was however in ſome degree clouded by great calamities of a phyſical nature. Tremendous earthquakes happened almoſt every year throughout the whole extent of the empire. A dreadful peſtilence ſpread from Peluſium in Egypt, over the greateſt part of Aſia, Africa, and Europe. During the ſpace of three months, from five to ten thouſand individuals died daily in Conſtantinople. Many cities in the Eaſt were almoſt depopulated, and in ſome parts of Italy, the harveſt rotted on the ground. This contagion, which began in the fifteenth year of Juſtinian's reign, was not extinguiſhed in leſs than fifty-two years.

Juſtinian died in the year 565. Soon after his death the Eaſtern empire began to decline. After the ſucceſſive reigns of Juſtin II. and of Tiberius, which filled up the interval, from the death of Juſtinian to the acceſſion of Maurice in 582, a ſpirit of revolt manifeſted itſelf in Conſtantinople, and terminated in the aſſaſſination of Maurice, and election of Phocas the centurion in 602. Phocas was in his turn depoſed and put to death by Heraclius, A. D. 610, whoſe reign is remarkable for a moſt obſtinate conteſt with Perſia, to which country it proved finally fatal.

During a period of twelve years, from 610 to 622, the Eaſtern empire exhibited a ſcene of almoſt unexampled diſtreſs. From the Adriatic to the ſuburbs of Conſtantinople, the provinces were ravaged by the Chan of the Avars, who had ſubdued the Huns and reſided in the royal village of Attila, in the great plain of Hungary; and a Perſian army was encamped at Chalcedon, now Scutari, on the brink of the Boſphorus, directly oppoſite to Conſtantinople. The general conſternation was ſo great that the emperor was about to leave the city, and tranſport himſelf with the treaſures of the imperial palace to Carthage, when the patriarch of Conſtantinople led him to the altar of the church of St. Sophia, and made him take a ſolemn oath that he would live and die with his people. Heraclius having thus ſolemnly bound himſelf to the defence of his country, carried devaſtation to the very centre of the Perſian dominions. He every where defeated the numerous forces of Choſroes, whoſe continual diſaſters excited a general revolt of the Perſians. Choſroes was depoſed A. D. 628, and Siroes his ſon proclaimed king. The latter put to death his father and eighteen brothers, and then concluded with Heraclius a treaty of peace, in conſequence of which, the former boundaries of the Byzantine and Perſian empires were reſtored.

The northern nations, which had overthrown the Roman empire in the Weſt, were yet in an unſettled ſtate, and Europe exhibited the moſt diſguſting ſcene of barbariſm and anarchy, whilſt Conſtantinople was triumphing in the ſucceſsful termination of a war, which had threatened the extinction of its empire. It was, however, ſoon to witneſs horrors ſimilar to thoſe with which the Weſt had been familiarized for the ſpace of two centuries.

About the year 609, Mahomet, an Arabian, aſſumed the character of a prophet, and aſſembling together a determined and daring band, in whom he excited military enthuſiaſm by means of religious tenets, calculated to flatter their paſſions, he ſubdued one after another, all the Arabian tribes, and attacked the Eaſtern empire three years before his death. His ſucceſſor, Abubeker, preferred, however, turning his arms towards Perſia, which had not yet recovered from the confuſion into which it had been thrown, by the dreadful conteſt between Heraclius and Choſroes. But after the death of Abubeker, which happened in 634, Omar, who ſucceeded him, aſſailed the Byzantine empire, with renovated ardour. In the courſe of a very few years, both Syria and Egypt acknowledged the ſway of the conqueror. The loſs of Egypt was ſeverely felt by the people of Conſtantinople; that country having always been eſteemed the granary of the city, and Syria, being in poſſeſſion of an enemy, laid all the Aſiatic provinces open to invaſion.

In the year 644, this new Saracen empire devolved to the Caliph Othman, who completed the conqueſt of Perſia, and ſubdued all that part of Africa, which had ſucceſſively been under the dominion of the weſtern and eaſtern empire, and which extended from Egypt to the Atlantic, and from the Mediterranean to the Great Deſert.

But during the whole period of the exiſtence of the Saracen empire, Conſtantinople ſtill reſiſted all the attacks of theſe Arabian conquerors. They twice laid ſiege to the city. In their firſt attempt their fleet blockaded Conſtantinople, on the ſide of the Propontis, from 668 to 675. Their ſecond ſiege in 716, was rendered memorable by the invention of the Greek fire, which totally deſtroyed the Saracen fleet, whilſt the army which attacked the city on the land ſide, was compelled to raiſe the ſiege with prodigious loſs.

If the progreſs of Mahometaniſm was hurtful to the intereſts of Chriſtianity, and to the ſplendour of the Byzantine empire, the conteſt between the advocates of the uſe of images in Chriſtian temples and their opponents, which violently agitated the church, proved equally fatal in its conſequences. It occaſioned the firſt ſchiſm between the Greek and Latin churches, and was the origin of thoſe differences which in the end produced their total ſeparation, and haſtened the fall of Conſtantinople.

This diſpute broke out about the year 720, in the reign of Leo, the Iſaurian, who is diſtinguiſhed in hiſtory as the firſt of the Iconoclaſt emperors. A council was held at Conſtantinople in 754, by 338 prelates of the eaſtern empire, who condemned all viſible repreſentations of Chriſt and his apoſtles, as heretical. This deciſion immediately cauſed the ſeceſſion of Italy. A new Roman republic was eſtabliſhed; but not being able to maintain its independence againſt the Lombards, it was delivered from their oppreſſion by Pepin, king of France, whoſe ſon and ſucceſſor Charlemagne received from the pope Adrian IV. the title of emperor of the Romans, and founded the Holy Roman or German empire.

The decree of the council of Conſtantinople did not, however, maintain its authority for more than thirty years. Irene, an Athenian female, who for her beauty had been advanced to the imperial bed and throne, began to reign in conjunction with her ſon Conſtantine VI. in the year 780. Her ambition inſtigated her to cauſe the eyes of her ſon to be put out that ſhe might reign ſole empreſs of the Eaſt. She ſtrongly exerted herſelf in favour of the reſtoration of images, which the ſecond council of Nice, condemning that of Conſtantinople, effected in 787. Still the two churches of the Eaſt and Weſt, were never more cordially united.

During the four centuries which elapſed between the death of Theodoſius the Great and the reign of Charlemagne, Europe was in a ſtate of anarchy and barbariſm: the eaſtern empire alone exhibited marks of civilized ſociety, and for a while flouriſhed in power, till it was curtailed of half of its poſſeſſions by the conqueſts of the Mahometan caliphs. Under Charlemagne the whole world was divided into the Eaſtern, Saracen, and new Weſtern empire. Of theſe the Saracen empire, under the caliphs, ſtood the higheſt in literary attainments; Conſtantinople, though much declined, ſtill held the ſecond rank; and the reſt of Europe was making ſome advances towards the reſtoration of learning, when Charlemagne, by dividing his new empire among his ſons, replunged it into barbariſm.

In the ninth century, the Bulgarians, who had commenced their attacks towards the latter end of the ſeventh, and renewed their inroads at different periods, continued to be formidable enemies. They were completely ſubdued by Baſilius II. towards the end of the tenth century. It was about the ſame time that the empire of the Saracens, being, like that of Charlemagne, ſplit into a number of independent ſtates, by the revolt of factious and ambitious chiefs, fell a prey to the Seljukian Turks and other barbarous nations of Aſia. This ſubverſion of the caliphate was attended with the complete wreck of Arabian learning; and the Byzantine empire remained the ſole depoſitory of all that was worthy of notice in literature, commerce, and the arts and embelliſhments of civilized ſociety. Thus the tenth century, which, in the weſtern countries, was one of the darkeſt periods of Gothic ignorance, conſtituted the moſt flouriſhing æra of the Byzantine learning, under the reigns of Leo the philoſopher and his ſon Conſtantine Porphyrogenitus.

About the year 1063 the emperor Conſtantine XI. Ducas left, at his death, the empire to his three ſons, Michael, Andronicus, and Conſtantine XII., and appointed the empreſs Eudocia regent during their minority, on condition that ſhe ſhould not marry again. But having been releaſed from her engagement, through a ſtratagem practiſed upon the patriarch, who abſolved her of the oath ſhe had taken, Eudocia married an officer of great military merit, named Romanus Diogenes, who was proclaimed emperor. After various ſucceſſes againſt the Turks, who were continually encroaching upon all ſides of the empire, Romanus was wounded in a deſperate engagement, and taken a priſoner. Before his return to Conſtantinople, Eudocia was driven from the throne by John, the brother of Conſtantine Ducas, and her eldeſt ſon, Michael Ducas, proclaimed emperor. Romanus was beſieged in a ſtrong caſtle, whither he had retired, and killed in the year 1067, after a reign of three years and eight months.

Immediately after the death of Romanus, the empire was again invaded by the Turks. In leſs than ten years they made themſelves maſters of all Media, Lycaonia, Cappadocia, and Bithynia. At laſt Alexius Comnenus, having wreſted the empire from Nicephorus Botoniates, who had depoſed Michael Ducas, prepared for war with ſo much vigour, that Solyman the Turkiſh ſultan made propoſals of peace, to which Alexius acceded, in order to defend himſelf in the weſt againſt the Italians, under Robert Guiſchard, duke of Puglia and Calabria, whom he defeated, with the aſſiſtance of the Venetian fleet. He alſo forced the Scythians, who had laid waſte great part of Thrace, to ſubmit on his own terms.

The war with the Turks was renewed in 1083, and carried on with various ſucceſs. But about the year 1095, a romantic ſcene of religious enthuſiaſm and military enterpriſe began to diſplay itſelf; and though it threatened the utter ruin of the Turkiſh nation, proved finally fatal to Conſtantinople.

Under the poliſhed empire of the caliphs, the frequent pilgrimages of Chriſtians to the holy ſepulchre at Jeruſalem had been encouraged; but the barbarians who had overturned the caliphate oppreſſed the pilgrims with unreaſonable impoſitions, and often added inſult to injuſtice. Incenſed at theſe outrages, Peter, a hermit, who had viſited the holy ſepulchre, preached a cruſade for the recovery of the holy land from the infidels. The pope approved the project, and the princes and nobles of Europe readily entered into the meaſure.

This religious war was carried on, with ſome intervals, during the ſpace of almoſt two hundred years, from the ſetting out of the firſt cruſade in 1095, to the loſs of Acre and all Paleſtine in 1291. Innumerable armed hordes were collected out of England, France, Germany, the Netherlands, and Italy. Yet theſe tremendous efforts were not attended with effects of ſuch permanency as might have been expected. But one of the moſt remarkable events which occurred in the courſe of the cruſades, was the capture of the city of Conſtantinople by the Latins.

The emperor, Iſaac Angelus, having been depoſed and deprived of ſight by his inhuman brother, his ſon, Alexius, who was only a youth, made his eſcape into Italy, and met with a number of the barons of France and Flanders, who were come to Venice to contract with the republic for the ſhips neceſſary to facilitate one of thoſe cruſading enterpriſes. He concluded with them a treaty, whereby they engaged to reſtore his father to the imperial throne of the Eaſt, and he promiſed to unite the Greek to the Latin church. The French and Venetians, changing the deſtination of their armament, ſailed up the Helleſpont to Conſtantinople, broke the chain of the harbour, and aſſaulted the city. When they were almoſt ready to enter the town, the uſurper made his eſcape. Iſaac Angelus and his ſon, the young Alexius, were proclaimed joint emperors. A ceſſation of arms took place: but as ſoon as the clergy underſtood the terms of the treaty concluded by young Alexius, they reprobated the idea of an union with the ſee of Rome, and excited the people to fly to arms. The inſurrection was alſo fomented by Alexius Mourzouſle, of the family of Ducas, who aſſumed the purple, impriſoned the blind emperor Iſaac, and put young Alexius to death. The legal ſucceſſion of the Greek empire being thus overturned, the French and Venetians recommenced the war. After a ſiege of more than three months, they aſſaulted the city from the harbour, and carried it by ſtorm, eight hundred and eighty years after its foundation by Conſtantine. The city being given up to pillage, the plunder was valued at 400,000 marks, nearly equivalent to 800,000*l.* ſterling, the greateſt ſum ever found in any captured city previous to that period; and notwithſtanding the penalties of excommunication, and even of death, denounced againſt any one who ſhould ſecrete any part of the ſpoil, the ſecret plunder is ſuppoſed to have exceeded what was produced in public. Baldwin, earl of Flanders, was elected emperor, with one-fourth part of the empire for his ſhare: the reſt was divided among the barons and knights, into fiefs, held under the emperor.

The Greeks, after this diſaſter, eſtabliſhed independent ſtates at Nice, Trebiſond, and Epirus. The Latins were not proſperous in their newly-acquired empire. The diſſentions which prevailed among the barons, laid their dominions open to the attacks of the Greeks. They continually gained ground. The Bulgarians alſo revolted, and the emperor, Baldwin of Flanders, being defeated and taken priſoner by them, died in captivity. He was ſucceeded by his brother Henry, who ſhewed himſelf of equal capacity for peace and war.

Henry checked the proceedings of the popiſh legate, in the perſecution of the Greek ſchiſmatics. But after his death, which happened in 1216, the Latin empire of Conſtantinople rapidly declined: and ſo preſſing were the exigencies of the ſtate, that Baldwin II., the laſt emperor of the Latin dynaſty, pledged to the Venetians the crown of thorns pretended to have been worn by Chriſt.

At laſt Michael Paleologus, having uſurped the Greek empire of Nice, his general, Alexius Strategopulus, with an inconſiderable force, ſurpriſed and recovered Conſtantinople in 1261: and thus, after a period of 57 years, that metropolis returned under the dominion of the Greeks. But a conſiderable part of the city had been deſtroyed in the three dreadful conflagrations which happened at the time of the ſiege and capture by the Latins: Conſtantinople never more regained that ſplendour which it had all along maintained. The imperial palace, which, during eleven centuries, had been the admiration of all who viſited the Eaſt, was in ruins. It ſtood between the Hippodrome and the magnificent church of St. Sophia. Its ſuperb gardens deſcended, by ſeveral rows of terraces, to the ſhore of the Propontis. The primitive edifice, erected by Conſtantine, rivalled the palace of the Cæſars on the Palatine Mount. The improvements made by his ſucceſſors ſtill added to its magnificence; and the emperors of the Comnenian dynaſty had taken particular delight in embelliſhing this imperial reſidence.

The inveterate enmity of the clergy and people of Conſtantinople againſt the Latin church ſtill ſubſiſted. To avert a cruſade, which the Latins were meditating againſt Conſtantinople, Michael Paleologus negociated with the pope, and concluded a concordat between the Greek and Latin churches; but at his death, in the year 1282, the union was diſſolved. His ſon Andronicus, who ſucceeded him, reſtored the ancient Greek ceremonies, and by this imprudent ſtep threw the empire into a new ferment.

In the mean time Conſtantine his brother ſucceſsfully oppoſed the Turks, who continued their encroachments: but his valour rendered him ſuſpected by the emperor. Conſtantine was thrown into priſon. On his removal from the army, the Turks under the famous Othoman made themſelves maſters of ſeveral places. Philantropenus and Libadarius, two officers of great merit, were ſent to oppoſe them. The former gained ſome advantages over the enemy: but elated with his ſucceſs he cauſed himſelf to be proclaimed emperor. This rebellion however was ſoon ſuppreſſed. Philantropenus was betrayed by his own men: but the Turks taking advantage of theſe inteſtine commotions extended their dominions in Aſia, conquered moſt of the iſlands in the Mediterranean, and infeſted the coaſts of the empire. Andronicus, not truſting his ſubjects, hired the Maſſagetes to aſſiſt him: but they being defeated, turned their arms againſt him. He next applied to the Catalans who behaved in the ſame manner, and, in 1292, aſſailed the empire in conjunction with the Turks. This was their firſt appearance in Europe. Their enterpriſe this time proved unſucceſsful.

New commotions having taken place in the empire, the Turks returned to the charge in 1327. The next year, however, Othoman, who may be ſtyled the founder of the Turkiſh monarchy, being dead, the emperor recovered Nice and ſome other places, which were again loſt the year following; and, in 1330, a peace was concluded, which left the Turks in poſſeſſion of their conqueſts.

This peace the Turks broke in 1357. Having reduced all Aſia, they paſſed the Helleſpont, and took a ſtrong caſtle on the European ſide. Soon after ſultan Amurath, advancing ſtill farther, made Adrianople the ſeat of his empire. He was ſlain by treachery, and ſucceeded by his ſon Bajazet, who levied a yearly tribute on the emperor of Conſtantinople, and commanded him to ſend him his ſon Manuel to attend him in his military expeditions. This demand was complied with. But the emperor dying in 1392, Manuel haſtened to Conſtantinople without taking leave of the ſultan. This incenſed Bajazet ſo highly, that he paſſed with great expedition into Thrace, ravaged the country adjoining Conſtantinople, and at laſt inveſted the city both by ſea and land. In this extremity, Manuel had recourſe to the weſtern princes, who ſent him an army of 130,000 men, under the command of Sigiſmund, king of Hungary, and John count of Nevers. After a few ſucceſſes they were defeated with great ſlaughter by Bajazet, who reſumed the ſiege of the city, and would infallibly have accompliſhed the conqueſt of Conſtantinople had he not been obliged to turn his forces againſt Tamerlane the victorious Tartar, by whom he was overcome in battle, and confined in an iron cage againſt the bars of which he beat out his brains in the year 1399.

But as this relief could not be expected to be of long duration, Manuel Paleologus ſet ſail for Venice, and from thence viſited London and Paris in the year 1400, in the reign of Henry IV. of England and Charles VI. of France, with the view of procuring ſome aſſiſtance, which the circumſtances of thoſe countries did not permit them to grant. He alſo endeavoured to negociate an union with the Latin church; but the negociation broke off. His ſon John Paleologus, who ſucceeded him, was more fortunate. He concluded a treaty at Florence with pope Eugenius IV.; but it was univerſally reprobated by the whole body of the clergy of Conſtantinople, and the emperor was obliged to renounce it. He did not long ſurvive theſe unhappy diſturbances, and, in 1448, left the empire now confined almoſt within the walls of Conſtantinople to the laſt Conſtantine.

Upon the near proſpect of being beſieged in his capital by the Tartar Turks, Conſtantine Paleloogus renewed the concordat with the Latin church. A cardinal legate from Rome was admitted at Conſtantinople; but after he had officiated in the cathedral of St. Sophia, the Greek clergy abandoned it as a polluted temple, and the whole city of Conſtantinople diſplayed every extreme of fanaticiſm and averſion againſt the Latin church. Though reduced to a narrow corner between the Propontis and the Euxine, the Byzantine empire continued the theatre of crimes and political as well as fanatical factions, until the 29th of May, 1453, when, after a ſiege of 53 days, Conſtantinople was taken by the Turks under Mahomet II. Whatever may have been the ſtrength of the army which the Turks brought againſt that celebrated metropolis, the force, which the miniſter was able to enrol by the emperor's command for its defence, was inconſiderable. There were only 4970 volunteers, and including the Italian auxiliaries, the emperor's troops did not exceed 8000 men.

Conſtantine Paleologus made a vigorous defence, and raſhly refuſed advantageous terms of capitulation. When the city was at laſt carried by aſſault, he nobly fell in the breach by which the enemy entered Conſtantinople. A ſhocking ſcene now followed. The perſons and property of the citizens were given up to the diſpoſal of the conquering army. The terrified people fled to the cathedral of St. Sophia and other aſylums, from whence they were dragged forth, and without any diſtinction of ſex or rank, chained together, driven through the ſtreets like beaſts, and more than ſixty thouſand of them ſold into ſlavery. Mahomet, at the expiration of the three days allotted for pillage, made his triumphal entry into Conſtantinople, which he named the capital of the Ottoman empire, and which has ever ſince held that ſtation. See TURKS.

Such was the dreadful cataſtrophe of Conſtantinople, once the metropolis and long the ſole exiſting remnant of the Roman empire. It fell a prey to the Turks 1043 years after Rome was taken by Alaric, and 977 years after the entire ſubverſion of the weſtern empire. Gibbon's Hiſt. of the Decline and Fall of the Roman Empire, *paſſim.* Le Beau, Hiſtoire du Bas Empire. Bigland's Letters on Ancient and Modern Hiſtory.

Conſtantinople is called by the Turks *Stampol*, *Iſtampol*, or (according to Thornton's preſent State of Turkey, p. 79.) *Iſtambol, abounding in faith.* It is ſituated at the eaſtern extremity of the province named Romania, or Romelia, on the European ſide of the Boſphorus, or ſtraits of Conſtantinople, which ſeparates Europe from Aſia; in N. lat. 41° 10'. 830 miles S. E. of Vienna and 900 E. of Rome. It riſes gradually from the ſhore in the form of an amphitheatre; but the ſtreets are narrow, and the houſes, in general, mean; the moſt ſpacious not exceeding two ſtories in height. The ſtreet called Adrianople is the longeſt and broadeſt in the city. The public buildings, ſuch as the palaces, the moſques, bagnios, bazars, and caravanſerais or khans, for the entertainment of ſtrangers, are many of them very magnificent. On one point of the triangle, on which the city is built, is the ſeraglio from whence there is a charming proſpect of the delightful coaſt of Aſia Minor. This incloſure of the Ottoman palace is ſeparated from Conſtantinople by a wall thirty feet high with battlements, embraſures, and towers, in the ſtyle of ancient fortifications. Its circumference is above ſix miles. There are in it nine gates, but only two of them remarkable for their ſize and beauty. It is from one of theſe the *Baba Hoomajun*, or *Sublime Porte*, that the Ottoman court is ſuppoſed to have taken the name of the *Porte*, or *Sublime Porte*, in all public tranſactions and records. But Mr. Thornton, in his preſent State of Turkey, page 117, contends that the palace of the grand vizir, by a metaphor familiar to moſt of the Eaſtern languages, is called the Porte or King's gate, in Perſian *Der*, being, as it were, the door of communication between the ſultan and his ſubjects, and correſponding with the European appellation of a court which follows the perſon of the ſovereign.

The ſeraglio is ſo extenſive, that it is ſuppoſed to occupy the whole of the ground on which the ancient city of Byzantium ſtood, and to contain 10,000 inhabitants. That wing of the ſeraglio which is excluſively appropriated to the ladies of the Grand Signor, is called the *Harem.* Among the ancient monuments preſerved in the ſeraglio, is the tomb of Conſtantine the Great. Of the moſques, or Turkiſh churches, the moſt celebrated is that of St. Sophia, which fronts the great gate of the ſeraglio, and is thought, in ſome reſpects, to exceed in grandeur and architecture St. Peter's at Rome. Round it are ſeveral chapels, which ſerve as burial-places for the imperial family. The other moſques of ſultan Achmet, ſultan Mahomet, ſultan Selim, ſultan Solyman, and ſultan Bajazet, are alſo very fine. Theſe imperial moſques are founded chiefly by ſultans, who have obtained victories, and devote the ſpoils of war, gained from the enemies of their religion, to the ſervice of public worſhip, the inſtruction of youth, and the relief of the poor. Foundations of this kind are annexed to every moſque. There are in Conſtantinople 518 ſeminaries of learning, and 1250 primary ſchools. The Greeks, beſides their patriarchal church, dedicated to St. George, have 22 others. The palace of their patriarch is on a hill, about two hundred paces from the harbour. The Armenians have an archbiſhop and three churches; the Roman Catholics have ſix convents, and the Jews ſeveral ſynagogues. There is alſo a Swediſh Lutheran church.

The bazars, or beſeſtins, anſwer to our markets. They are ſquares encloſed within gates, where merchants meet for traffic, having generally two rows of ſhops built under piazzas. The market of female ſlaves, *Avrat Bazar*, is a quadrangle, ſurrounded by a covered gallery, and ranges of ſmall and ſeparate apartments; but Mahometans only are admitted.

The bagnios, or public baths, are elegant and noble ſtructures, built with hewn ſtones; the inner chambers are capacious, and paved with ſlabs of the rareſt and moſt beautiful marble.

At the ſouth end of the city, is the formidable ſtate priſon of the ſeven towers, built of fine free-ſtone, and ſurrounded by a wall, with ſeveral ſmaller towers.

There are no theatres at Conſtantinople; the *Ombres Chinoiſes*, which are ſometimes exhibited in the ſtreets, ſupply the want of dramatic exhibitions. Of other public amuſements, the principal are wreſtling, and throwing the javelin, on horſeback, in the ancient Hippodrome, an oblong ſquare, called by the Turks *Almeidan.*

Conſtantinople counts 35 public libraries, ſome of which contain 15,000 volumes. That which was founded under Muſtafa III. by the vizir Racub Pacha, is the moſt modern. A renegado, of the name of Ibrahim, encouraged by the grand vizir, Ibrabim Paſha, and the Mufti Abd'ullah Effendi, introduced the firſt printing-preſs at Conſtantinople, in the year 1727. It was afterwards deſtroyed by ſome fanatics, but Abdul Hamid reſtored it. Only the Koran, and books treating of the law and the doctrines of the prophet, are forbidden to be printed. Theſe circulate in manuſcripts, and afford a comfortable ſubſiſtence to 20,000 individuals who live by copying them.

The trade of Conſtantinople is chiefly in the hands of the Jews, Armenians, and Greeks; and its commerce is carried on by foreigners of all nations, who are confounded under the general name of Franks. No reſtrictions are laid on commerce, except in the articles neceſſary for the ſupport of human life; the exportation of which is ſometimes prohibited, eſpecially from Conſtantinople, where alone the prohibition is rigorouſly enforced. Beſides ſilk, cotton, wool, flax, drugs, coffee, ſugar, wax, honey, fruits, hides, and tobacco, Conſtantinople exports its own printed muſlins, the ſatins, ſilk ſtuffs, and velvets, of Bruſa and Aleppo, the ſerges and camelots of Angora, the crapes and gauzes of Salonica, the ſword-blades of Damaſcus, and the carpets of Smyrna. The harbour is ſpacious, and ſuppoſed capable of holding 1200 ſhips. Near it is *Galata*, a ſuburb chiefly inhabited by Greeks, Armenians, Jews, and Franks, who have their warehouſes here. Beyond this is *Pera*, which may be conſidered as the ſuburb of Galata, where the foreign ambaſſadors reſide. The air is uncommonly healthy, and the proſpect delightful. Near Pera is the quarter called *Tophana*, from its canon foundery.

According to Mr. Dallaway, the population of Conſtantinople, including its ſuburbs, does not exceed 400,000 ſouls, of whom 200,000 are Turks, 100,000 Greeks, and the remainder Jews, Armenians, and Franks, or ſtrangers from all the European nations. Mr. W. Eton (in his Survey of the Turkiſh Empire, ſecond edition, page 287.) brings it down to leſs than 300,000. But this computation is evidently too low. At the time of its capture by the Latins, Conſtantinople is ſuppoſed by Villehardouin to have contained 400,000 effective men; this, however, muſt be regarded as an exaggeration. Mr. Le Beau, in his Hiſtoire du Bas Empire, ſuppoſes that it contained then about one million of inhabitants, and that its preſent population amounts to 400,000, which, by all accounts, is the moſt probable computation.

Conſtantinople is frequently viſited by the plague, which, however, excites but little alarm, and Turkiſh indifference counteracts all efforts to ſubdue this dreadful epidemical diſorder. From the year 1783 to 1785, it ſwept away 100,000 children and young people. The city has alſo often been expoſed to great conflagrations. In 1782 a fire conſumed from 7 to 8000 houſes, among which were ſome belonging to the firſt officers of the ſtate. On the 5th of Auguſt, 1784, more than 10,000 buildings were laid in aſhes, and towards the end of the ſame year, 1600 houſes and moſques were burnt down. In 1788 there was ſo extenſive a conflagration as to threaten the entire deſtruction of the city. They generally originate in the diſcontents of the Janizaries, or other military bodies. In the laſt revolution, which they effected on the 28th of May, 1807, when they forced Selim III. to abdicate the throne, and proclaimed Muſtapha IV. emperor: they contented themſelves with cutting off the heads of a few miniſters and military chiefs. But between the firſt and ſixth day of Auguſt following, three great fires reduced ſeveral hundred houſes to aſhes, and are ſuppoſed to have proceeded from the ſtrong diſſatisfaction that prevailed in the mutinous army againſt the new grand ſignor, for having iſſued an order to pay the troops only in the camp. In time of peace the Janizaries watch over and ſecure the public tranquillity, and exerciſe all the functions of police officers. A foreigner, who would be inſulted if ſeen alone in the ſtreets of Conſtantinople, may walk any where without the leaſt moleſtation if accompanied by a Janizary. See JANIZARIES. (D'Ohſſon Tableau General de l'Empire Ottoman. Eton's Survey of the Turkiſh Empire. Thornton's preſent State of Turkey.)

CONSTANTINOPLE, *Patriarch of.* See *Greek* CHURCH.

CONSTANTIUS, FLAVIUS VALERIUS, in *Biography*, ſurnamed *Chlorus* from the paleneſs of his complexion, was ſon of Eutropius, a Dardanian noble, but his education did not correſpond with the ſtyle of his birth. Under the emperors Aurelian and Probus, he had learned the military art, and by the emperor Carus, he was appointed governor of Dalmatia in the year 282. Ten years afterwards, in conjunction with Galerius, he was made Cæſar, and aſſociated with the emperors Diocletian and Maximian. To Conſtantius were aſſigned the provinces of Gaul, Britain, and Spain. At this time Carauſius, an ambitious general, had excited a revolt in Britain, and carried matters ſo far as to aſſume the imperial authority; he was alſo in poſſeſſion of the port and fleet of Boulogne. To oppoſe the uſurper, Conſtantius firſt attacked Boulogne, which ſurrendered to his arms, together with a great part of the naval ſtrength of the place. After this, Conſtantius employed three years in preparing a fleet for the conqueſt of Britain; he ſcoured the coaſt of Gaul, invaded the country of the Franks, and deprived the uſurper of the aſſiſtance of thoſe allies. Before the preparations were finiſhed, Carauſius was depoſed and murdered by his own ſervants. Allectus, his prime miniſter, ſucceeded to his power and to his danger. But he did not poſſeſs equal abilities, either to exerciſe the one or to repel the other. Conſtantius, under favour of a thick fog, eſcaped the Britiſh fleet, and landed in ſafety on the weſtern coaſt, where an engagement took place, in which Allectus was ſlain; a ſingle battle decided the fate of this great iſland, and when Conſtantius landed afterwards on the ſhores of Kent, he found them covered with obedient ſubjects. He now had occaſion only to exert his talents in eſtabliſhing a regular government; to which he appears to have been fully competent; he reigned with mildneſs, and was anxious not to oppreſs his ſubjects by heavy taxes; his court was diſtinguiſhed by ſimplicity and great frugality, and he himſelf was a decided enemy to the perſecutions which diſgraced the reigns of Diocletian and Maximian; but in which, as their ſuperior, he was obliged occaſionally to join. When, however, he roſe to the ſupreme power of Auguſtus, he baniſhed perſecution entirely from the provinces over which he governed. That event occurred in 305. Finding his health decline, he ſent, as we have ſeen, (ſee CONSTANTINE *the Great*,) for his ſon Conſtantine to join him at Boulogne, thence they failed to Britain, where the Picts had made an incurſion into the northern part of the Roman province. This expedition, and an eaſy victory over the barbarians of Caledonia, were the laſt exploits of the reign of Conſtantius. He cloſed his days in the imperial palace of York, fifteen months after he had received the title of Auguſtus, and near fifteen years after he had been promoted to the rank of Cæſar. His death was immediately ſucceeded by the elevation of Conſtantine the Great; beſides whom, he left three ſons and as many daughters, by a ſecond wife. Moreri. Gibbon.

CONSTANTIUS II., FLAVIUS JULIUS, was the ſecond ſon of the great Conſtantine, by Fauſta, and born in 317. At a very early period of his life he was declared Cæſar: when even a ſtripling, the care of the Eaſt was committed to him. On the death of his father, being then in his twentieth year, he repaired to Conſtantinople where he took a ſolemn oath that his kinſmen, who were already in diſcredit with the ſoldiery, ſhould be permitted to remain in ſafety. He is however accuſed of an utter diſregard to the ſanction of the oath, and of having excited the maſſacre in which his two uncles, and ſeven of his couſins, were put to death. In a new diviſion of the empire, in the year 338, Aſia, Syria, Egypt, and Thrace were allotted to Conſtantius. From this period he was involved in wars with various nations; of which the moſt important was that with Magnentius, in Lower Pannonia. In the firſt campaign Conſtantius was ſo far unſucceſsful, that he offered terms of accommodation, and a partition of his dominions, which his opponent haughtily refuſed, propoſing as the only ground of ſolid peace the abdication of Conſtantius. A very bloody and deciſive battle ended in a ſignal defeat of Magnentius, who with difficulty eſcaped to Italy. Conſtantius ſpent the winter in Sirmium, the place of his birth, and in the ſpring of the following year 352, he paſſed the Alps, and proceeded to the conqueſt of Italy, a taſk of no great difficulty on account of the enmity which the cruelties of Magnentius had excited againſt him and his cauſe. He now attempted to treat, but his overtures were not liſtened to: from Italy he paſſed to Gaul, and made a ſtand at Lyons. Africa, Sicily, and Spain, declared for his rival. Another victory over Magnentius, rendered Conſtantius, in 353, the ſole maſter of the Roman empire; but Magnentius, and his brother Decentius, choſe death by their own hands, rather than run the chance of falling into thoſe of their conquerors.

The conduct of Conſtantins upon this important change, has been variouſly repreſented; but there is no doubt that meaſures of the ſevereſt kind were carried on againſt thoſe who had engaged againſt him, or had rendered themſelves liable to ſuſpicion. Notwithſtanding his talents and ſucceſs as a general, he was by no means equal to the duties attaching to the high office of emperor, and he dreaded too much a rival, to place the government under the auſpices of a vigorous mind. His chief adviſers were eunuchs, with whom his court was crowded, and to whom he committed the fortunes and lives of his numerous ſubjects. Conſtantius had already declared his nephew Gallus, Cæſar, and to him was given the care of the Eaſt, where he diſplayed the moſt atrocious acts of tyranny, and exhibited an intention of aſſuming an independent ſovereignty. By the advice of Euſebius, the chamberlain of the eunuchs, Gallus was recalled, impriſoned, and executed. Thoſe who write favourably of Conſtantius, aſſert, that he had no ſooner ſigned the warrant, than he relented, and endeavoured to recal the bloody mandate; but that the ſecond meſſenger entruſted with the reprieve, was detained by the eunuchs, who dreaded the unforgiving temper of Gallus, and were likewiſe deſirous of re-uniting to their empire the wealthy provinces of the Eaſt. Some time after this event, Sylvanus, a Frank, who had been in the confidence of the emperor, and who had been of the utmoſt importance to him in his conteſts with Magnentius, was, by falſe accuſations, driven into rebellion. He aſſembled an army at Cologne, but was aſſaſſinated before it could be properly organized. The barbarian tribes of Germany, reſolving to be revenged for his death, burſt into the province, deſtroyed many cities, and among the reſt Cologne itſelf, and reduced the empire to the moſt alarming danger. Julian, the remaining nephew of the emperor, was ſent againſt them, and returned victorious. In 357, Conſtantius paid a viſit to Rome, where he was received with the higheſt honours. He diſplayed his regard for the ancient capital, by adding to its ornaments an obeliſk of granite in a ſingle piece, brought from Egypt, and ſet up in the Circus Maximus. After this, he engaged in other wars, and was in general ſucceſsful. His nephew Julian became now his rival; his high reputation in the army, induced the ſoldiers to proclaim him Auguſtus, but the emperor refuſed to acknowledge him as partner in the empire, and began to make preparations to aſſert his own rights over thoſe of his aſpiring relation. Julian had anticipated him, and had already ſeized upon Illyricum; in purſuit of him there, Conſtantius was ſeized with a fever, which at firſt threatened no ſerious conſequences, but which terminated his life, and thus delivered the country from the horrors of a civil war. He died in November 361, having reigned twenty-four years. He obtained the character of a zealous Chriſtian, and is applauded for having diſcouraged Pagan rites and ceremonies. He built many churches, and behaved with great reſpect towards the clergy; in matters of ſpeculation and theological controverſy, he conſidered himſelf an adept; was himſelf a favourer of the Arian party, and the perſecutor of Athanaſius, and of thoſe who maintained his doctrines. It muſt be confeſſed that the genuine principles of Chriſtianity were never underſtood by any of the Roman emperors; and their ſupport of it, however laudable their motives might be, was highly injurious to its progreſs in the world. Gibbon. Univer. Hiſt.

CONSTAT, in *Law*, the name of a certificate, which the clerk of the pipe, and auditors of the exchequer, make at the requeſt of any perſon, who intends to plead or move in that court for the diſcharge of any thing; and the effect of it is, the certifying what (appears) *conſtat* upon record, touching the matter in queſtion. 3 & 4 Edw. VI. cap 4. and 13 Eliz. cap. 6.

A conſtat is held to be ſuperior to an ordinary certificate; becauſe this may err or fail in its contents, that cannot, as certifying nothing but what is evident upon record. Alſo the exemplification under the great ſeal of the inrolment of any letters patent, is called a *conſtat*. Coke on Littl. 225.

CONSTELLATION, in *Aſtronomy*, an aſſemblage or ſyſtem of ſeveral ſtars, expreſſed and repreſented under the name and figure of ſome animal, or other thing: this aſſemblage is by ſome called alſo an *aſteriſm*.

The ancients portioned out the firmament into ſeveral parts, or conſtellations; reducing a certain number of ſtars under the repreſentation of certain images, in order to aid the imagination, and the memory, to conceive and retain their number, diſpoſition, and even to diſtinguiſh the virtues, which aſtrologers attributed to them: in which ſenſe a man is ſaid to be born *under a happy conſtellation*, i. e. under a happy configuration of the heavenly bodies. The diviſion of the heavens into conſtellations is very ancient, and, probably, as old as aſtronomy itſelf; at leaſt, it was known to the moſt ancient authors extant, whether ſacred or profane. In the book of Job, mention is made of the names of ſome of them; as in chap. ix. 9. "Which maketh Arcturus, Orion, and Pleiades, and the chambers of the ſouth." By the "chambers of the ſouth," ſome have underſtood the conſtellations near the ſouth pole, which are inviſible to the inhabitants of the northern hemiſphere. From the manner in which Job ſpeaks of commerce, we may infer that he lived in a country frequented by merchants, who imported thither the rarities of the ſouth. To this purpoſe Sir Iſaac Newton ſuggeſts, (Chronology, p. 157.) that Job, who lived in Arabia Petræa, among the merchants, might have derived from them his knowledge of the conſtellations. And again, mention of them occurs in that ſublime expoſtulation, chap. xxxviii. 31, 32. "Canſt thou reſtrain the ſweet influence of the Pleiades, or looſen the bands of Orion? Canſt thou bring forth Mazzaroth, (by which ſome underſtand the twelve ſigns, or zodiac,) or canſt thou guide Arcturus with his ſons?"

The firſt of the three conſtellations, mentioned by Job, is עש *aſch*, or עיש *aiſch*, by which ſome have thought that he meant the conſtellation, now called the "Great Bear." The root of *aiſch* is עוש *ouich*, which, in Hebrew, ſignifies, "to gather together, or to aſſemble;" and in Arabic, "to make a circuit, or to deſcribe a circle." Theſe two ſignifications may very well be applied to the Great Bear, which is a group of ſtars making a remarkable circuit round the pole. "Canſt thou guide (or feed) *Aiſch* with his ſons?" (chap. xxxviii. v. 32.) is an expreſſion which figuratively repreſents the ſtars that compoſe the Great Bear, collected together, like a flock which feeds in a meadow. In the ſame ſtrain Virgil ſays, (Æn. l. I. v. 611.) "Polus dum ſidera paſcet." It has been further obſerved, that *Aiſch* is the firſt ſtar named in Job; and that Αρκτος, or the Great Bear, is the firſt conſtellation mentioned by Homer, in his deſcription of the ſhield of Achilles. The ſecond conſtellation or group of ſtars mentioned by Job is כימה *kimah*. From the different paſſages in which this term occurs, we may reaſonably conclude, that it muſt be underſtood of ſome conſtellation remarkable for its relation to an agreeable ſeaſon. God ſays to Job, "Canſt thou bind the ſweet influences of *Kimah?* i. e. Canſt thou bind up or reſtrain the fertility of the earth, for producing fruits and flowers, when *Kimah* appears?" The different ſignifications of this word, both in the Hebrew and Arabic, concur in pointing out the ſame ſenſe of the term. *Kimah* may be derived from כמה *kamah*, which, in Hebrew, ſignifies, "to deſire, or to rejoice." Of all the ſeaſons the ſpring is the moſt deſirable, and the moſt productive of delight and joy. If we deduce the word *kimah* from the Arabic root *kevuam*, or *kam*, this characteriſes the ſpring as diſtinctly as the former. *Kam*, in Arabic, ſignifies, "ſubigere mulierem," and "to become warm." Accordingly, the earth, at the approach of ſpring, begins to become warm, and to open its boſom: this is alſo the time when the females of moſt kinds of animals become pregnant. It remains only to know, what was the conſtellation which in the time of Job introduced the ſpring; and this, as we have ſufficient reaſon for believing, was the Pleiades. *Kam* alſo ſignifies a "troop, number, or multitude:" and this etymology agrees perfectly well with the Pleiades, on account of the number of ſtars included in this collection, or in the conſtellation of the Bull.

The third conſtellation mentioned by Job is כסיל *keſil*; the root of which word is כסל *kaſal*, which, in Hebrew, ſignifies, "to be inconſtant or changeable:" and in Arabic, "to be benumbed, to be idle, to be cold." By *Keſil*, therefore, it is ſuppoſed that Job means the Scorpion. God ſays to Job, "Canſt thou looſen the bands of *Keſil?*" i. e. "Canſt thou looſen and open the earth, which is ſhut up and benumbed when *Keſil* appears? Canſt thou then make it produce flowers and fruits?" Adverting to the interpretation already given of *kimah*, we ſhall perceive, by the contraſted characters which diſtinguiſh them, that they are two conſtellations of the zodiac, pointing out two very oppoſite ſeaſons. If by *kimah* Job deſigned the Pleiades, it is not improbable that by *keſil* he meant the Scorpion, a conſtellation oppoſed to Pleiades by almoſt one-half of the circuit of the heavens, and which then announced the approach of winter. Accordingly, Aben-Ezra underſtood by *keſil* that ſtar of the firſt magnitude, known by the name of the Scorpion's heart, or Antares. In his commentary on Job he thus explains himſelf: "*Kimah,*" ſays he, "is the northern ſtars, and *Keſil* is a ſouthern ſtar. *Kimah* produces fruits, which are the delight of man; and *Keſil* does the contrary. *Kimah* is a great ſtar, called the Bull's eye, that is to ſay, Hyades; and *Keſil* is a great ſtar, called the Scorpion's heart, that is to ſay, Antares." Rabbi Levi Ben-Gerſon ſays alſo, in his commentary on Job, that *Keſil* is one of the ſouthern conſtellations; and that when the ſun enters into the ſign where this ſtar is found, the trees can no longer bring forth fruit, on account of the cold which this ſtar brings with it. *Keſil* has been ſuppoſed, by ſome learned commentators and critics, to denote the conſtellation Orion, which, at the time of its riſe, portends clouds and tempeſts; and they derive it from כסל *kaſal*, denoting inconſtancy. See Schultens's Commentary on Job, vol. i. p. 239, &c. vol. ii. p. 1086. Goguet's Origin of Laws, &c. vol. i. Diſſert. 3.

In the prophecy of Amos, who is ſuppoſed to have lived 790 years B. C., we have the following animated exhortation (chap. v. 7, 8.): "Ye who turn judgment into wormwood, and leave off righteouſneſs in the earth; *ſeek him* that maketh the ſeven ſtars and Orion, and turneth the ſhadow of death into the morning, and maketh the day dark with night; that calleth for the waters of the ſea, and poureth them out upon the face of the earth: the Lord is his name." In this paſſage, the ſeven ſtars and Orion are mentioned as being well known, both by Amos, who was a herdſman of Tekoa, and the common people, to whom this exhortation was addreſſed; and we may hence infer, that the conſtellations had been invented for ſome time before that period. Some of the conſtellations are alſo occaſionally mentioned by Heſiod and Homer, who flouriſhed above 900 years before Chriſt; and Aratus of Tarſus, the aſtronomical poet, who lived about 277 years B. C., in his "Phenomena," profeſſedly treats of them all, except ſome few which were invented after his time; ſhewing how each conſtellation is ſituated with regard to thoſe that are near it, what poſition it bears with reſpect to the principal circles of the ſphere, and what other conſtellations riſe or ſet with it. Hipparchus, the Bithynian, has ſhewn, that Aratus followed the deſcriptions of Eudoxus, who flouriſhed about 366 years B. C.; and it is very probable that the Greek aſtronomers who ſucceeded him continued to uſe the ſame figures of the conſtellations till the time of Ptolemy, though not without ſome variations and additions. Ptolemy's Almageſt (ſee Almagest) has been in ſuch eſteem among aſtronomers, that almoſt all who have written ſince his time have agreed in drawing the figures of the conſtellations, or ſuppoſing them to be drawn, ſo as to anſwer his deſcription, as far as poſſible; and indeed this is neceſſary, in order to avoid confuſion, when ancient and modern obſervations are compared.

The diviſion of the ancients only took in the viſible firmament, or ſo much as came under their notice: this they diſtributed into forty-eight conſtellations, thoſe being reckoned ancient conſtellations which have been received from the Greeks, and particularly from Ptolemy; twelve of theſe took up the zodiac: the names they gave them are, *Aries*, *Taurus*, *Gemini*, *Cancer*, *Leo*, *Virgo*, *Libra*, *Scorpio*, *Sagittarius*, *Capricornus*, *Aquarius*, *Piſces:* from whence the ſigns of the ecliptic and zodiac take their names; though they are now no longer contiguous to the conſtellations which denominate them; *e. g.* the conſtellation Aries, about 2000 years ago, occupied the place of the firſt ſign of the ecliptic; but, on account of the preceſſion of the equinox, it is now removed to the ſecond; and ſo of the others. See Sign.

The other ſtars, on the northern ſide of the zodiac, were diſpoſed into twenty-one conſtellations; viz. *Urſa*, *major* and *minor*, *Draco*, *Cepheus*, *Bootes*, *Corona Septentrionalis*, *Hercules*, *Lyra*, *Cygnus*, *Caſſiopeia*, *Perſeus*, *Andromeda*, *Triangulum*, *Auriga*, *Pegaſus*, *Equuleus*, *Delphinus*, *Sagitta*, *Aquila*, *Ophiuchus* or *Serpentarius*, and *Serpens:* to which have been ſince added *Antinous*, and *Coma Berenices*, and ſome others.

The ſtars on the ſouthern ſide of the zodiac were diſtributed into fifteen conſtellations: their names are, *Cetus*, *Eridanus fluvius*, *Lepus*, *Orion*, *Canis*, *major* and *minor*, *Argo*, *Hydra*, *Crater*, *Corvus*, *Centaurus*, *Lupus*, *Ara*, *Corona Meridionalis*, and *Piſcis auſtralis:* to which have been ſince added ſeveral others, viz. *Phœnix*, *Grus*, *Indus*, *Pavo*, *Apus* or *Avis Indica*, *Apis Muſca*, *Chamæleon*, *Triangulum auſtrale*, *Piſcis volans*, *Toucan*, *Hydrus*, *Xiphias* or *Dorado*, *Columba Noachi*, and *Robur Carolinum*, &c. &c. See each conſtellation under its proper head, Aries, Taurus, &c.

The other ſtars, not comprehended under theſe conſtellations, yet viſible to the naked eye, the ancients called *informes*, or *ſporades*, ſome of which the modern aſtronomers have ſince reduced into new figures, or conſtellations.

Thus, Hevelius, v. gr. between *Leo* and *Urſa major*, makes *Leo minor*; and between *Urſa minor*, and *Auriga*, over *Gemini*, makes *Lynx;* under the tail of *Urſa major*, *Canes venatici*, *Cerberus*, *Vulpecula*, and *Anſer*, *Scutum Sobieſki*, *Lacerta*, *Camelopardalus*, *Monoceros*, and *Sextans*. See alſo Antinous, Berenice, and Cor *Caroli*.

In theſe conſtellations, the ſtars are ordinarily diſtinguiſhed by that part of the image wherein they are found. Bayer diſtinguiſhes them farther by the letters of the Greek alphabet: and many of them, again, have their peculiar names, as *Arcturus*, between the knees of Bootes; *Gemina*, or *Lucida*, in the Corona ſeptentrionalis; *Palilitium*, or *Aldebaran*, in the Bull's eye, *Pleiades* in the neck, and *Hyades* in the forehead of the Bull: *Caſtor* and *Pollux* in the heads of Gemini; *Capella*, with the *Hædi*, in the ſhoulder of Auriga: *Regulus*, or *Cor Leonis; Spica Virginis* in the hand, and *Vindemiatrix* in the ſhoulder of Virgo; *Antares*, or *Cor Scorpionis; Fomahaut*, in the mouth of Piſcis-auſtralis; *Regel*, in the foot of Orion; *Sirius*, in the mouth of Canis major; *Procyon*, in the back of Canis minor; and the *Poleſtar*, the laſt in the tail of *Urſa minor*.

The knowledge of the ſtars has become more extenſive; the number of conſtellations has increaſed; and a greater number of ſtars has been introduced into each conſtellation; as their poſitions, by more accurate obſervations, have been aſcertained.

The following tables exhibit the names of the conſtellations, and the number of ſtars in each, including all to the ſixth magnitude: and alſo ſome of the moſt remarkable ſtars in each conſtellation.

TABLE I. *Conſtellations in the Zodiac.*

Names of Conſtellations.	*Number of the Stars.*				*Chief Stars.*	
	Ptolemy.	Tycho.	Hevelius.	Flamſteed, &c.		Magn
Aries, the Ram	18	21	27	66		
Taurus, the Bull	44	43	51	141	Aldebaran	1
Gemini, the Twins	25	25	38	85	Caſtor and Pollux	1. 2
Cancer, the Crab	13	15	29	83		
Leo, the Lion	with Coma Berenices 35	30	49	95	Regulus	1
Virgo, the Virgin	32	33	50	110	Spica Virginis	1
Libra, Chelæ, the Scales	17	10	20	51	Zubenich Meli	2
Scorpio, the Scorpion	24	10	20	44	Antares	1
Sagittarius, the Archer	31	14	22	69		
Capricornus, the Goat	28	28	29	51		
Aquarius, the Water-bearer	45	41	47	108	Scheat	3
Piſces, the Fiſhes	38	36	39	113		

TABLE II. *Conſtellations northward of the Zodiac.*

Names of the Conſtellations.	*Number of Stars.*				*Chief Stars.*	
	Ptolemy.	Tycho.	Hevelius.	Flamſteed, &c.		Magn.
Urſa minor, the Little Bear	8	7	12	24	Poleſtar	2
Urſa major, the Great Bear	35	29	73	87	Dubhe	1
Perſeus	29	29	46	59	Algenib	2
Auriga, the Waggoner	14	9	40	66	Capella	1
* Bootes	23	18	52	54	Arcturus	1
Draco, the Dragon	31	32	40	80	Raſtaber	3
* Cepheus	13	4	51	35	Alderamin	3
* Canes Venatici, *viz.* Aſterion, et Chara, the Greyhounds	-	-	23	25		
* Cor Caroli	-	-	-	3		
* Triangulum, the Triangle	4	4	12	16		
Triangulum minus	-	-	-	10		
* Muſca	-	-	-	6		
* Lynx	-	-	19	44		
* Leo minor, the Little Lion	-	-	-	53		
* Coma Berenices, Berenices' hair	-	14	21	43		
* Camelopardalus	-	-	32	58		
* Mons Menelaus	-	-	-	11		
Corona Borealis, the Northern Crown	8	8	8	21		
Serpens, the Serpent	13	13	22	64		
Scutum Sobieſki, Sobieſki's Shield	-	-	7	8		
Hercules cum Ramo & Cerbero, Hercules, ſince called Engonaſia	29	28	45	113	Ras Algiatha	3
* Serpentarius, ſive Ophiuchus	29	15	40	74	Ras Alhagus	3
* Taurus Poniatowſki	-	-	-	7		
Lyra, the Harp	10	11	17	22	Vega	1
* Vulpeculus & Anſer, the Fox and Gooſe	-	-	27	37		
Sagitta, the Arrow	5	5	5	18		
Aquila, the Eagle,	-	12	23	71	Altair	1
— with Antinous,	-	3	19			
Delphinus, the Dolphin	10	10	14	18		
Cygnus, the Swan	19	18	47	81	Deneb Adige	1
Caſſiopea, the Lady in her chair	13	26	37	55		
Equulus, the Horſe's head	4	4	6	10		
* Lacerta, the Lizard	-	-	-	16		
Pegaſus, the Flying Horſe	20	19	38	89	Markab	2
Andromeda	23	23	47	66	Almaac	2

TABLE III. *Conſtellations ſouthward of the Zodiac.*

Names of the Conſtellations.	*Number of the Stars.*				*Chief Stars.*	
	Ptolemy.	Tycho.	Hevelius.	Flamſteed, &c.		Magn.
* Phœnix				13		
* Officina Sculptoria				12		
Eridanus	34	10	27	84	Achernar	1
* Hydrus, the Waterſnake				10		
Cetus, the Whale	22	21	45	97	Menkar	2
* Fornax Chemica				14		
* Horologium				12		
* Reticulus Rhomboidalis				10		
* Xiphias, Dorado, the Sword-fiſh				7		
* Celapraxitellis				16		
Lepus, the Hare	12	13	16	19		
* Columba Noachi, Noah's Dove				10		
Orion	38	42	62	78	Betelgeuſe	1
Argo Navis, the Ship	45	3	4	64	Canopus	1
Canis Major, the Great Dog	29	13	21	31	Sirius	1
* Equuleus Pictorius				8		
* Monoceros, the Unicorn			19	31		
Canis Minor, the Little Dog	2	2	13	14	Procyon	1
* Chamæleon				10		
* Pyxis Nautica				4		
* Piſcis Volans, *Paſſer*, the Flying Fiſh				8		
Hydra	27	19	31	60	Cor Hydræ	1
* Sextans			11	41		
* Robur Carolinum, the Royal Oak				12		
* Machina Pneumatica				3		
Crater, the Cup	7	3	10	31	Alkes	3
Corvus, the Crow	7	4		9	Algorab	3
* Croſiers, el Cruzero				6		
* Apis Muſca, the Bee or Fly				4		
* Apus or Avis Indica, the bird of Paradiſe				11		
* Circinus, the Compaſs				4		
Centaurus, the Centaur	37			35		
Lupus, the Wolf	19			24		
* Quadra Euclidis				12		
* Triangulum Auſtrale, the Southern Triangle				5		
Ara, the Altar	7			9		
* Teleſcopium				9		
Corona Auſtralis, the Southern Crown	13			12		
* Pavo, the Peacock				14		
* Indus, the Indian				12		
* Microſcopium				10		
* Octans Hadleianus				43		
* Grus, the Crane				14		
* Toucan, the American Gooſe				9		
Piſcis Auſtralis, the Southern Fiſh	18			24	Fomelhaut	1

N. B. In the preceding Tables the new Conſtellations are diſtinguiſhed from the ancient by a ſtar, *.

TABLE IV. *Number of Stars of each Magnitude.*

	20	76	223	510	695	1604	3128

There are ſeveral ways of delineating the conſtellations and ſtars, ſo that an obſerver may be able to diſtinguiſh them in the heavens. The moſt eligible method of all is to conſtruct a hollow globe of ſuch a large ſize as to admit the obſerver to ſtand on a frame near its centre; and then to paint the ſtars and conſtellations in its inner ſurface, in their proper ſituations with regard to one another. If ſuch a globe, elevated according to the latitude, were made to turn on its poles, the obſerver near the centre would behold the motions and aſpects of the ſtars as they really are in the heavens, and ſoon obtain a correct idea of the whole. A machine of this kind, however, could not be conſtructed without a very conſiderable expence as well as ingenuity. Large machines on this plan have been made at Gottorp, at the expence of Frederick III. duke of Holſtein; and at Paris by the direction of cardinal d'Etrees; but theſe are far inferior in ſize to one erected at Pembroke college, in Cambridge, under the direction of Dr. Long. The deſcription of this curious machine is here ſubjoined in the doctor's own words. "I have, in a room lately built in Pembroke hall, erected a ſphere of 18 feet diameter, wherein 30 perſons may ſit conveniently: the entrance into it is over the ſouth pole by ſix ſteps:—the frame of the ſphere conſiſts of a number of iron meridians, not complete ſemicircles, the northern ends of which are ſcrewed to a large round plate of braſs with a hole in the centre of it; through this hole, from a beam in the ceiling, comes the north pole, a round iron rod about three inches long, and ſupports the upper parts of the ſphere to its proper elevation for the latitude of Cambridge; the lower part of the ſphere, ſo much of it as is inviſible in England, is cut off: and the lower or Southern ends of the meridians, or truncated ſemicircles, terminate on, and are ſcrewed down to a ſtrong circle of oak, of about thirteen feet diameter, which, when the ſphere is put into motion, runs upon large rollers of lignum vitæ, in the manner that the tops of ſome wind-mills are made to turn round. Upon the iron meridians is fixed a zodiac of tin, painted blue, whereon the ecliptic and heliocentric orbits of the planets are drawn, and the conſtellations and ſtars traced:—the great and little bear, and draco, are already painted in their places round the north pole; the reſt of the conſtellations are propoſed to follow: the whole is turned round with a ſmall winch, with as little labour as it takes to wind up a jack, though the weight of the iron, tin, and wooden circle, is about a thouſand pounds. When it is made uſe of, a planetarium will be placed in the middle thereof. The whole, with the floor, is well ſupported by a frame of large timbers." In 1758, the conſtellations and chief ſtars viſible at Cambridge, were painted in their proper places upon plates of iron joined together, which form one concave ſurface. We here add with regret, that this curious machine has been much neglected and is ſo far decayed as to anſwer none of the purpoſes which the ingenious contriver propoſed. The conſtellations and ſtars might alſo be drawn in two concave hemiſpheres, which would contain them all, or ſegments of ſpheres might be made of braſs or paſteboard, of ſuch dimenſions that each ſegment ſhould contain a ſingle conſtellation upon its concave ſurface. Sometimes the conſtellations are drawn upon two planiſpheres projected upon a great circle, which give us the pictures of the two concave hemiſpheres in plano. See our *Plates of Conſtellations*. The conſtellations and ſtars may be alſo depicted on a celeſtial globe.

The firſt uſe of all theſe concave ſpheres, planiſpheres, and globes is, by comparing them with the originals, to know the ſtars in the heavens; but as the rotation of the earth round its axis cauſes the heaven and ſtars, &c. apparently to move the contrary way; and thus the ſphere of the fixed ſtars is made to change its poſition, with reſpect to us, every moment of the natural day: it will be neceſſary, in order to compare the ſtars upon a concave hemiſphere, globe, or planiſphere, with the ſtars in the heaven, to place the globe, hemiſphere, &c. in ſuch a poſition as to correſpond with the ſituation of the heavens at the time of obſervation. The method of rectifying the celeſtial globe for any hour of the night, or ſo to place it that every ſtar on the globe may point at the correſponding ſtar in the heavens, will be ſhewn under the article *Celeſtial* GLOBE; and when this is done, the conſtellation may be known, by comparing the heavens and the globe with one another. *E. G.* If I would find a ſtar called Arcturus in the heavens, the globe being rectified for the hour, I find Arcturus upon it; then if I imagine a line to be drawn from the centre of the globe through that ſtar, that line continued will point at Arcturus in the heavens. Suppoſe, on the other hand, I ſee ſome bright ſtar in the heavens which I want to find upon the globe, I firſt rectify the globe for the hour of the night, and then if I imagine a line to be drawn from the ſtar to the centre of the globe, it will point at the correſponding ſtar on the ſurface of the globe. Maps of the concave ſurface of the heavens, eſpecially ſuch as take in only one conſtellation, with ſome parts of thoſe which ſurround it, are very uſeful for the purpoſe of becoming acquainted with the ſtars. Of this ſort are the figures given by Bayer in his "Uranometria," and thoſe of Flamſteed, publiſhed after his death by Hodgſon. See our *Plates of Conſtellations*. The manner of uſing theſe maps will be ſeen by the following example. If I would know the ſtars in the Great Bear, I turn the figure about, till the principal ſtars of it are in the ſame ſituation with regard to upper or under, right or left, as they appear in the heavens, at the time of making my obſervation: when this is done, it is eaſy, by looking firſt on the heavens and then upon the map, to diſcover to what parts of the figure, whether to the eye, ſnout, &c. the reſt of the ſtars are to be referred.

It is very probable that the ſtars, and more eſpecially ſome of the moſt remarkable collections of them, ſuch as Charles's Wain, the Pleiades, Orion, &c. were formed into conſtellations and had names given them, in the early ages of the world. Some of them, by their different appearances, ſerve to mark out the different ſeaſons of the year, and on that account they were not only taken notice of as a kind of directory for the commencement of ploughing, ſowing, and other operations of huſbandry (ſee Heſiod, Oper. et Dier., l. ii. v. 1 and 2.), but were alſo thought to have a great influence on the temperature of the air and the fertility of the earth. Hence, from their being *ſigns*, pointing out the times of the year when heat or cold, dryneſs or moiſture, are uſually predominant, they were alſo regarded as the cauſes of thoſe qualities in natural bodies, and imagined to have dominion over minerals, vegetables, and animals, over the complexions, and conſtitutions, and even the diſpoſitions of mankind. This opinion obtained credit the more eaſily, becauſe the ſun, moon, planets, and ſtars, were believed to be of a divine nature; inſomuch that ſome conceived they were inhabited by an inferior kind of deities, which governed their motions and directed their influences; whilſt others thought that they were animals, each of which had a living ſoul, which was guided by an intelligence, and others again ſuppoſe that they were animated by a part of the ſubſtance of the ſupreme Being. Each of theſe notions led mankind to pay them a ſort of religious worſhip. The moſt ancient idolaters are with great probability thought by ſome learned men to have received the name of Zabii from their worſhip of the hoſt of heaven; and this they could hardly do, without dividing the ſtars into parcels, as we find their apteſt ſcholars in idolatry, the Egyptians, did, who divided the heavens into ſeveral regions, which they called the ſtations or manſions of their gods. The Egyptians worſhipped the heavenly bodies; and more eſpecially the ſun and moon, which they called their great gods, denominating the ſun Oſiris, and the moon Iſis. They alſo found, or imagined that they found, in various animals, ſome properties or qualities correſponding to the motions, appearances, or influences of the ſun, moon, and ſome of the ſtars: hence they were induced not only to uſe thoſe animals in their hieroglyphic repreſentations of their deities, but alſo to pay them divine honours. Thus by the *ram, aries*, a prolific animal, they repreſented the genial fertilizing warmth of the ſun in the ſpring, as they did his violent ſcorching heat in the ſummer, by the hot and furious beaſt, the *lion*. The *bull* was regarded by them as another emblem of the various powers of the ſun in forwarding the operations of agriculture, to which this animal is ſubſervient; and hence were derived their *Apis* or *Mnevis*. The *goat* had divine honours paid him in ſome parts of Egypt, as a repreſentative of the tendency of univerſal nature to propagate the ſeveral ſpecies of beings; whence the Greeks took their image of *Pan*. *Virgo* was a repreſentation of their goddeſs Iſis: the *Scorpion* was an emblem of the deſtructive power of the malignant genius Typhon; the *triangle* was a picture of the land of Egypt, which is of this ſhape; the *balance* was the hieroglyphic of juſtice, and therefore *Libra* was thought to be a proper conſtellation for that part of the heavens wherein the ſun appears at one of the equinoxes, where he diſtributes equal day and night to the whole earth: or, in its relation to the land of Egypt, it may intimate the equal diſtribution of the Nile to the ſeveral parts of the country, by the genius of the waters; for the figure of this conſtellation was among the Egyptians a man holding a pair of ſcales. The Egyptians worſhipped *ſerpents* and *fiſhes*: and the *altar* is ſaid to have been an hieroglyphic of the land of Egypt. Many other ſimilar inſtances might be adduced, as moſt of the animals and other figures that occur among our preſent conſtellations were originally Egyptian. The Greeks, who learned aſtronomy of the Egyptians, retained ſeveral of their figures, as the ram, the bull, the lion, the dog, the triangle, &c.; but accommodated almoſt all of them to the fabulous hiſtory of their gods and heroes, whom they thus placed among the ſtars. Accordingly the Greek and alſo the Roman poets, from the ancient theology, have given us wild and romantic fables about the origin of the conſtellations, probably derived from the hieroglyphics of the Egyptians, and tranſmitted, with ſome alterations, from them to the Greeks; which may be ſeen in Hyginus's Poeticon Aſtron. and Ricciolus's Almageſt, lib. vi. cap. 3, 4, 5; and Sherburne's notes upon Manilius.

Sir Iſaac Newton obſerves, (ſee his Chronology, apud Oper. vol. v. p. 64.) that Muſæus, one of the Argonauts, was the firſt among the Greeks who made a ſphere; and the ſphere itſelf, he ſays, ſhews that it was delineated in the time of the Argonautic expedition; for that expedition is delineated in the Aſteriſms. Thus we have the golden *Ram*, the enſign of the veſſel in which Phryxus fled to Colchis; the *Bull* with brazen hoofs tamed by Jaſon; and the twins, *Caſtor* and *Pollux*, two of the Argonauts, with the *Swan* of Leda their mother. We have alſo the ſhip *Argo*, and *Hydrus* the watchful dragon: with Medea's *cup*, and a *Raven* upon its carcaſe, the ſymbol of death. We have *Chiron* the maſter of Jaſon, with his *altar* and *ſacrifice*; the Argonaut *Hercules* with his *dart* and *vulture* falling down, and the *Dragon*, *Crab*, and *Lion*, which he ſlew; and the *Harp* of the Argonaut Orpheus. All theſe, ſays ſir Iſaac, relate to the Argonauts. We have alſo *Orion*, the ſon of Neptune, or, as ſome ſay, the grandſon of Minos, with his *Dogs*, and *Hare*, and *River*, and *Scorpion*. We have the ſtory of Perſeus in the conſtellations of *Perſeus*, *Andromeda*, *Cepheus*, *Caſſiopea*, and *Cetus*; that of Calliſto, and her ſon Arcas, in *Urſa major* and *Arctophylax*; that of Icareus and his daughter Erigone in *Bootes*, *Plauſtrum*, and *Virgo*. *Urſa minor* relates to one of the nurſes of Jupiter; *Auriga* to Erechthonius; *Ophiuchus* to Phorbas; *Sagittarius* to Crolus the ſon of the nurſe of the Muſes; *Capricorn* to Pan; and *Aquarius* to Ganimede. We have Ariadne's *Crown*, Bellerophon's *Horſe*, Neptune's *Dolphin*, Ganimede's *Eagle*, Jupiter's *Goat*, with her *Kids*; Bacchus's *Aſſes*, the *Fiſhes* of Venus and Cupid, and their parent the *South-fiſh*. Theſe with *Deltoton* are the old conſtellations mentioned by Aratus; and they all relate, ſays Newton, to the Argonauts and their contemporaries, and to perſons one or two generations older; and nothing later than that expedition was delineated there originally. Antinous and Coma Berenices are novel. Although it be true, as ſir Iſaac Newton affirms, that none of the figures on this ſphere bear relation to any tranſaction of later date than the Argonautic expedition; yet the great diſagreement that ſubſiſts among mythologiſts in their accounts of theſe figures ſhews them to be of greater antiquity, and that the conſtellations were received for ſome time among the Greeks, before their poets, according to their ſeveral fancies, applied them to different fables. See Long's Aſtronomy, vol. i. p. 162.

As the ſtars grouped in our conſtellations are capable of being reduced to very different figures, thoſe of the Chineſe and Japaneſe are very different from ours; and ſome ſuperſtitious Arabians, though they received their aſtronomy from the Greeks, have given ſome of their conſtellations different figures; becauſe they thought it unlawful to draw any human figure; and therefore they changed all ſuch on the celeſtial globe into ſome other form. Some Chriſtian aſtronomers, diſpleaſed to ſee the heavens of the fixed ſtars occupied by the fabulous heathen deities and heroes have propoſed, from ſuperſtitious zeal but without a due regard to the ſcience of aſtronomy, to introduce a reformation in this reſpect; and whilſt they retained the ancient figures, to refer them to ſome ſcripture hiſtory. With this view they would have *Aries,* or the ram, to be a memorial of that which was offered inſtead of Iſaac, *Virgo* to repreſent the bleſſed Virgin, &c. Thus, venerable Bede, inſtead of the profane names and figures of the twelve conſtellations of the zodiac, ſubſtituted thoſe of the twelve apoſtles; whoſe example being followed by Julius Schillerius, in 1627, he completed the reformation, and gave ſcripture names to all the conſtellations in the heavens. Thus, *Aries,* or the ram, became converted into St. Peter; *Taurus,* or the Bull, into St. Andrew; *Andromeda* into the ſepulchre of Chriſt; *Lyra* into the manger of Chriſt; *Hercules* into the Magi coming from the Eaſt; *Canis major* into David, &c. Weigelius, profeſſor of mathematics in the univerſity of Jena, made a new order of conſtellations; converting the firmament into a *cœlum heraldicum;* and introducing the arms of all the princes in Europe, by way of conſtellations. Thus, *Urſa major,* he transformed into the elephant of the kingdom of Denmark; the *Swan* into the Ruta with ſwords of the houſe of Saxony; *Ophiuchus* into the croſs of Cologne; the *Triangle* into the compaſſes, which he calls the *ſymbol of artificers;* and the *Pleiades* into the *Abacus Pythagoricus,* which he calls that of merchants, &c. However, the more intelligent among aſtronomers never approved of innovation; as ſerving no purpoſe but to introduce confuſion into aſtronomy. The old conſtellations, therefore, are ſtill retained; both becauſe better could not be ſubſtituted, and likewiſe to keep up the greater correſpondence and uniformity between the old aſtronomy and the new. See Catalogue.

CONSTERNATION is defined by ethical writers to be an exceſs of horror, owing to the ill government of our *admiration* and *fear:* or ſuch an immoderate degree of *fear* as confounds the faculties, and incapacitates a perſon for conſultation and execution. It denotes a ſtrong foreboding of tremendous evils, that are likely to follow misfortunes which have already taken place.

CONSTIPATION, in *Medicine,* is ſynonymous with *coſtiveneſs,* and ſignifies a retention of the ſtools beyond the uſual period; which likewiſe implies, in general, a dry and hardened condition of the excrements, and ſome difficulty in diſcharging them.

The proximate cauſe of conſtipation of the bowels may conſiſt in an unuſual ſlowneſs of the periſtaltic motion, or in an obſtruction to the paſſage of the fæces, while the proper periſtaltic motion continues to propel them. The natural motion of the bowels is conſiderably different in individuals of different conſtitutions, and even in the ſame individuals at different periods: ſo that it is not eaſy to ſay when the periſtaltic motion can be conſidered as preternaturally ſlow, while the general health continues good. But it is probable that a ſtool ſhould occur once in 24 hours, in moſt habits, although there are many perſons who retain the fæces much longer without inconvenience. Dr. Cullen affirms, that he is clearly of opinion, that every deviation from a diurnal ſtool is an approach to an unnatural ſtate. The accumulation and induration of the fæces in the great inteſtines not only often produces many diſeaſes in the lower part of the canal, but even occaſions diſorders in diſtant organs, and deranges the ſyſtem in general.

The occaſional cauſes of an inefficient periſtaltic motion are various. A weakneſs of the muſcular coat of the bowels appears to be, in ſome caſes, the origin of coſtiveneſs, which is then accompanied with other marks of debility; hence coſtiveneſs is not unfrequent in the female ſex, who ſuffer conſiderable inconveniences from it. A cauſe of a contrary nature ſeems likewiſe to give riſe to conſtipation, namely, a rigour and rigidity of the alimentary canal. In ſuch caſes there is neceſſarily a degree of immobility or torpor, ſo that the ſtimulus of the paſſing fæces excites the inteſtines to leſs active motions, than in the more irritable habits; at the ſame time digeſtion is more perfectly performed, and a ſmaller proportion of fæces therefore is produced: the abſorption of the liquid parts too is more complete, and hence the fæces are not only ſmaller, but drier, and paſs leſs eaſily. In rigid and robuſt perſons therefore habitual conſtipation is not uncommon. And in thoſe of hypochondriacal or melancholic habits, a ſimilar torpor in the motions of the whole ſyſtem, and particularly of the inteſtinal canal, produces a ſimilar diſpoſition to coſtiveneſs. Another cauſe of the ſlowneſs of the periſtaltic motion may be a deficiency of *bile* in the inteſtines, which is conſidered as one of the principal ſtimuli in maintaining the motion of the canal downwards. It is not indeed always in our power to aſcertain the occurrence of this circumſtance; but we know that, where the bile is withheld from the inteſtines, as in jaundice, there is commonly conſtipation. It is not quite evident in what manner a regular and conſtant exerciſe of geſtation, as in a carriage or on the water, produces coſtiveneſs, rather than any conſiderable bodily activity, which is accompanied by much perſpiration; Dr. Cullen is diſpoſed to attribute it to the abſtraction of the other inteſtinal fluids, ſecreted from the mucous glands and exhalent arteries. See Materia Med. vol. ii. p. 496.

The cauſes which may obſtruct the paſſage of the fæcal matter, occur either in the inteſtines themſelves, or in the neighbouring parts. In the inteſtines, a mechanical impediment is ſometimes occaſioned by a thickening of the coats, which ſtraitens the paſſage, or by ſchirrous tumours, eſpecially near the lower extremity of the canal. Sometimes the cavity of the inteſtine is partly filled by calculous concretions. A temporary diminution of the calibre of the canal is alſo occaſioned by ſpaſmodic contractions in the coats, as occurs in colic, or by the occurrence of inflammation, as in *enteritis,* and *dyſentery;* in all of which the fæcal matter is retained. Tumours in the neighbouring parts, compreſſing the inteſtines, neceſſarily impede the paſſage of the contained fæces. Hence obſtinate conſtipation has ſometimes been occaſioned by a ſteatomatous tumour in the omentum; and a very frequent cauſe of coſtiveneſs is the compreſſion of the diſtended uterus upon the rectum, or lower gut, in pregnant women.

When, from neglect of evacuation, or other circumſtances, an accumulation of fæces to a conſiderable extent takes place in the rectum, or lower inteſtines, this collection of matter itſelf becomes a cauſe of a moſt painful and diſtreſſing conſtipation, attended with peculiar ſymptoms, and ſometimes terminating fatally. This diſorder was firſt deſcribed by an anonymous writer in the Medical Obſervations and Inquiries, vol. iv. p. 123, and other caſes have ſince been recorded by other practioners. (See Duncan's Medical Commentaries, vol. x. p. 255, and vol. xiii. p. 282.) It is the more important to attend to this complaint, becauſe it aſſumes the appearance of a *diarrhœa,* or rather a chronic dyſentery, and has been often miſtaken for the former, and erroneouſly treated with aſtringents and opiates in conſequence. The patient complains of ſevere pain about the lower region of the belly, remitting and again returning after frequent, but ſhort intervals, and accompanied with a perpetual bearing down, and almoſt continual inclination to evacuate the contents of the inteſtines; but only a trifling quantity of thin diſcharge is expelled, ſometimes mixed with ſmall knobs of hardened excrement, or ſcybala; after which the pain abates. A freſh ſpaſmodic effort ſucceeds, and with ſimilar ſucceſs. It may be conſidered as a kind of ſpontaneous ſpaſm of all the parts in, or connected with, the pelvis, for the excluſion of this irritating ſubſtance. When, from a previous coſtiveneſs, from the acuteneſs of the pain and *teneſmus* (or bearing down), and the obſtruction of formed and feculent ſtools, this ſtate of the rectum is to be ſuſpected, the gut ſhould be examined *per anum*, when the fæces will be readily detected in general, and muſt be broken down and removed by the finger, or ſome other mechanical means. The accumulation, which thus takes place, is ſometimes very great. The following account from an apothecary, is given by Dr. Warren of Taunton:—"the evening you left us, I extracted from our patient (a lady, aged 64, who had laboured under this diſeaſe for five months,) four large balls of hardened excrementitious matter, about the ſize of hen's eggs; the next morning ſhe diſcharged near twenty, and has continued to paſs more or leſs of them every day, until about a week ago, when ſhe took a larger doſe than ordinary of caſtor oil, which evacuated 18 lumps of the ſame ſize as formerly; ſince that her ſtools have been natural, none of the balls having appeared." See Duncan's Med. Com. vol. x. p. 259. This diſorder is peculiar to perſons in advanced life, when a degree of atony often exiſts in the bowels; and it is more frequently obſerved in the female, than in the male ſex. Whatever tends to leſſen the periſtaltic motion of the bowels, muſt induce a prediſpoſition to it; and it is ſaid to have been frequently occaſioned by a long continued uſe of bark, opium, and other aſtringent medicines.

The conſequences of a conſtipated ſtate of the bowels, however, though in a comparatively trivial degree, whether idiopathic, or as a concomitant of other diſeaſes, are frequently extremely injurious to the conſtitution; producing, when it is idiopathic, a variety of diſorders; and aggravating, when ſymptomatic, the diſeaſes of which it is a ſymptom.

The ſtomach and inteſtines, being a continuation of the ſame canal, reciprocally affect each other, when diſordered. Hence, complaints of the ſtomach are frequent conſequences of coſtiveneſs of the bowels; ſuch as flatulence, ſtomach colic, or gaſtrodynia, heart-burn, indigeſtion, &c. Another affection of the canal is frequently produced by conſtipation, namely, the appearance of hæmorrhoidal tumours, or piles, at the lower extremity of the rectum, about the anus. See HÆMORRHOIS. Sometimes from a ſympathy of the head with the ſtomach, and ſometimes probably from the preſſure of the loaded inteſtines on the great veſſels, impeding the circulation of the blood downwards, and therefore determining it more copiouſly towards the head, a pain of the head is excited by a conſtipated condition of the bowels. This head-ache is various in different inſtances, but moſt commonly is confined to the forehead, or to the *occiput*, or nape of the neck: occaſionally the hemicrania, or intermitting head-ache, appears to ariſe from conſtipation. In thoſe whoſe habits prediſpoſe them to apoplectic, paralytic, or lethargic attacks, a loaded ſtate of the bowels, by obſtructing the circulation downwards, increaſes the prediſpoſition, and occaſionally even becomes the exciting cauſe of thoſe diſeaſes.

There are, beſides, many diſorders both acute and chronic, which, although they cannot be ſaid to be produced by conſtipation of the bowels, are nevertheleſs greatly aggravated by it; and the conſtipation is frequently a leading ſymptom of theſe diſorders. Thus in all acute febrile complaints, and particularly in idiopathic and eruptive fevers, ſuch as the ſynochus, or ſummer-fever, typhus, ſcarlet-fever, ſmall-pox, &c. conſtipation is liable to occur, and when occurring at any period of the fever, tends to aggravate its ſymptoms, and to prolong its duration: and if, on the contrary, the bowels are freely opened in the commencement of theſe diſorders, their ſeverity is mitigated, and their duration frequently abridged. This is more eſpecially the caſe in ſynochus and typhus, and in the febrile complaints of children. In a certain ſet of chronic diſeaſes, which have heretofore been conſidered as unconnected with the condition of the bowels, ſuch as many hyſterical affections, chloroſis, and particularly chorea, or St. Vitus's dance, conſtipation has lately been ſhewn to be a ſource of much miſchief, if not frequently the exciting cauſe. (Hamilton on Purgatives.) See CHOREA, and CATHARTICS. In ſhort, a conſtipated ſtate of the bowels is at all times liable to produce injurious effects on the conſtitution: in health it is a common exciting cauſe of various complaints; and in all ſtates of diſeaſes, whether acute or chronic, it tends to aggravate the ſymptoms, and to prevent the beneficial operation of remedies.

The mode of obviating conſtipation muſt be varied, according to the nature of the cauſe, and the conſtitution of the patient. Where it is ſlight and accidental, any of the milder cathartics, ſuch as magneſia vitriolata, or Epſom ſalt, caſtor oil, (oleum ricini,) rhubarb, or ſmall doſes of calomel, will generally anſwer the purpoſe of removing it: if theſe fail, the more active purgatives muſt be reſorted to, eſpecially in ſtrong habits, ſuch as jalap, aloes, extract of colocynth, calomel in larger doſes, and combined with ſome of the preceding ſubſtances. Calomel, or the other mild mercurial preparations, appear to be peculiarly uſeful, when the conſtipation is occaſioned by a torpor of the hepatic ſyſtem, and a conſequent deficiency, or morbid change in the quality of the bile, as they appear to ſtimulate more particularly the biliary ducts and veſſels. The colour and fætor of the ſtools ſhould be noticed with care, ſince the quality and condition of the bile, which is the principal colouring matter of the fæces, may be thus moſt eaſily aſcertained. In acute diſeaſes this obſervation is more peculiarly important, as the ſenſible qualities of the fæces frequently indicate a loaded and morbid condition of the alimentary canal, and the neceſſity of laxatives, when the number of motions does not appear to require ſuch evacuation. See Hamilton; alſo Abernethy, Surgical Obſervations, vol. ii.

When conſtipation is habitual, ſome gently ſtimulating or cooling laxative, according to circumſtances, may be required to be given daily, until the habit be removed. Much may be done for the relief of this by diet; as by eating a large proportion of vegetables, or by the free uſe of fruits, even thoſe which are dried, or preſerved with ſugar; and by avoiding ſuch articles as manifeſtly tend to conſtringe the body. And the advice of Mr. Locke ſhould be ſteadily followed; *i. e.* the patient ſhould go regularly to ſtool at the ſame hour daily: for ſuch is the periodical regularity of all the functions of the body, that they are more perfectly performed at the accuſtomed hours than at any other period. Thus ſleep, and the appetite for food, often forſake us altogether, if we delay the gratification beyond the uſual hour.

In ſtates of extreme conſtipation it is very common among the vulgar to reſort to a medicine which appears to have been firſt employed from the moſt abſurd and falſe notions of its powers, namely, crude mercury, or quickſilver. Whether it may have been ſuppoſed to open the bowels by ſome ſelf-moving power, or by its mechanical weight, the theory is equally abſurd: and what is worſe, the practice is not only uſeleſs, but dangerous. There are caſes on record, in which the quickſilver, thus adminiſtered, had accumulated in the inteſtines, formed itſelf a ſac by its weight, and at length produced death, by paſſing into the cavity of the abdomen, in conſequence of the rupture of this ſac. It is obvious, indeed, that the medicine could not ever force a paſſage by its weight, along the courſe of the bowels, ſince it muſt aſcend occaſionally, if the body is erect; and the whole paſſage muſt be nearly horizontal, if the patient be in a recumbent poſture.

In the worſt degrees of conſtipation, glyſters conſiſting of an infuſion of tobacco, or the ſmoke of tobacco, have been thrown into the bowels with advantage. And when all other expedients have failed, the affuſion of cold water on the lower extremities while the patient is placed with his feet on a cold hearth, has been found to excite the propulſion of the fæces. See Colic. A glyſter conſiſting of Venice turpentine, ſuſpended in water by means of mucilage, or the yolk of an egg, was a favourite remedy with Dr. Cullen for ſevere conſtipation; and it is undoubtedly an efficacious expedient; more eſpecially if adminiſtered a few hours after an active cathartic has been taken internally.

Where the conſtipation is occaſioned by a mechanical obſtruction, it can of courſe be alleviated only by the removal of the obſtruction. If it ariſes from the preſence of tumours or concretions external to the bowels, it may be conſidered as incurable; and can only be alleviated by keeping the bowels lax, and the fæces in as liquid a ſtate as poſſible. Strictures of the lower inteſtine have been frequently relieved by the introduction of a bougie, mechanically enlarging the paſſage. An intelligent writer remarks, that "ſtrictures take place in different ſituations; but they occur ſo frequently about the ſigmoid flexure of the colon, near its termination in the rectum, that this part ſhould be carefully examined in every caſe of a total obſtruction of the bowels." The inſertion of an unyielding tallow candle, though often practiſed, has been generally found painful and inefficacious. It is requiſite for the purpoſe to employ a bougie thirteen inches long, and of a proportionate ſtrength; which ſhould alſo be directed, with a nice hand, by a ſkilful ſurgeon. "I lately ſaw a lady," he adds, "thus relieved, who had been twenty-ſix days without any evacuation from the bowels, and who ſeemed nearly exhauſted by violence of pain, and diſtenſion of the abdomen, hiccough, cold ſweat, &c. It is remarkable how long patients ſubſiſt under theſe diſtreſſing circumſtances. In one inſtance the time was twenty-nine days; in another patient thirty-three days. As the latter recovered after enduring every torture ſuch a diſorder could inflict, practitioners may be encouraged to perſevere ſteadily in their attentions, and to retain ſome hopes even in the greateſt extremity." Willan on Diſeaſes in London, page 185.

CONSTITUENT Parts, in *Chemiſtry*. The conſtituent parts of bodies are their diſſimilar parts, or principles, into which they may be reſolved, by the rules of that art. They are thus called in diſtinction from the integrant parts of bodies, which are parts of the ſame nature and properties with the bodies themſelves. Thus quickſilver, diſſolved by aqua fortis, may be ſeparated from the diluted menſtruum, by means of a copper plate, in its own form; this therefore was only divided into its integrant parts; but cinnabar reſolved by chemiſtry into ſulphur and mercury, is divided into its conſtituent parts, neither of theſe, nor any particle of them, being cinnabar, or having its properties. Shaw's Lectures, p. 15.

CONSTITUTION, an eſtabliſhment, ordinance, deciſion, regulation, or law, made by authority of a prince, or other ſuperior, eccleſiaſtical or civil.

The conſtitutions of the Roman emperors make a part of the civil law. The conſtitutions of the church make a part of the canon law. Some of the papal conſtitutions are in form of *bulls*, others of *briefs*. See each article.

Constitutions *of Clarendon*. See Clarendon.

Constitutions, *Clementine*. See Canon *Law*.

Constitutions, *Legatine*, were eccleſiaſtical laws enacted in national ſynods, held under the cardinals Otho and Othobon, legates from pope Gregory IX. and pope Clement IV., in the reign of Henry III., about the years 1237 and 1268.

Cardinal Otho arrived in England, as a legate from the pope, in the year 1237, where he continued about three years, receiving many valuable preſents from the biſhops, monaſteries, and clergy. This legate held a council at London, A. D. 1237, in which a great number of canons were framed, which were called "the Conſtitutions of Otho." Theſe conſtitutions do not contain many things new or remarkable. By the ſecond canon, the ſacraments are declared to be ſeven in number; the fifteenth is againſt the clandeſtine marriages of the clergy; and the ſixteenth againſt their keeping concubines publicly: both which practices were ſtill very frequent in England. This legate convened two other aſſemblies of the clergy, with no other view but to make exorbitant demands of money. After the reſtoration of the royal authority, by the victory of Eveſham, the pope ſent his legate Othobon into England, who held a national council, A. D. 1268, at St. Paul's in London. In this council many canons were made, much the ſame in ſubſtance with thoſe of the former council of London, in 1237, under the legate Otho.

Constitutions, *Provincial*, are principally the decrees of provincial ſynods, held under ſeveral archbiſhops of Canterbury, from Stephen Langton, in the reign of Henry III. to Henry Chicheley, in the reign of Henry V., and adopted alſo by the province of York in 1463, under Henry VI.

Constitutions *of* 1603. See Canon *Law*.

Constitutions, *Apoſtolical*, in *Eccleſiaſtical Hiſtory*, denote a collection of regulations attributed to the apoſtles, and ſuppoſed to have been collected by St. Clement, whoſe name they likewiſe bear.

Theſe are divided into eight books; conſiſting of a great number of rules and precepts, relating to the duties of Chriſtians, and particularly to the ceremonies and diſcipline of the church.

Mr. Robert Turner, in his "Diſcourſe of the pretended Apoſtolical Conſtitutions," maintains, that theſe eight books ſeem to have been made out of ſeveral doctrines, conſtitutions, canons, travels, and traditions, aſcribed to the apoſtles, and out of ſome of the ancient liturgies, and the diſcipline and practice of the Greek church, only blended together, adulterated, and changed, by ſome ignorant Arian, in the fifth century. Biſhop Pearſon was of opinion, that the Apoſtolical Conſtitutions were formed out of ſeveral leſſer works, called Doctrines and Conſtitutions, ſaid to be written by Clement, Ignatius, Hippolytus, and others, but altered and interpolated by the author of this collection; and that the eight books of the Conſtitutions, as we now have them, were not compoſed and finiſhed till after the time of Epiphanius.

Authors, however, are divided about the genuineneſs of theſe Conſtitutions: the generality hold them ſpurious, and endeavour to prove them poſterior to the apoſtolic age; maintaining they were unknown till the fourth century:

which, if this be the fact, ſhews, that St. Clement had no concern in them. It is certain, that no ſuch book is quoted as Scripture by any Chriſtian writer of the three firſt centuries. The firſt who cites a work under this title is Epiphanius, and yet he ſpeaks of it as of doubtful authority; and ſome modern writers are of opinion, that the Conſtitutions quoted by Epiphanius were different from the preſent Conſtitutions. When he ſays, that it was "doubted by many," he himſelf intimates, that ſome ſuſpected it to be the work of ſome heretic; in oppoſition to which he ſays, it ought not to be rejected, as, from its contents, it appeared to be the work of ſome honeſt, orthodox, or Catholic Chriſtian.

It is not eaſy to ſay, what reſpect Epiphanius himſelf had for this work. He quotes things from it as ordinances of the apoſtles, and as the divine word or doctrine; but it is not mentioned in any of the paſſages, where he gives the catalogues of the books of Scripture. Beſides, his expreſſions juſt taken notice of ſeem to imply no more, than that the book was an eccleſiaſtical or orthodox writing; and we may obſerve farther, either that his Conſtitutions were not the ſame as ours, or that he had no great regard for them. For in our Conſtitutions, ſeveral early heretics are named, and they are condemned and confuted; of which paſſages, nevertheleſs, Epiphanius has made no uſe in his hiſtory of thoſe heretics, or in his arguments againſt them: which every one muſt think he would have done, if the Conſtitutions which we have had been then in being, and had been eſteemed by him as of authority. Whatever might be his opinion concerning this work, we have no good reaſon for ſuppoſing that it was a book of ſacred Scripture; becauſe no ſuch book is quoted as Scripture by Irenæus, Clement of Alexandria, Origen, Cyprian, Euſebius, or any other Chriſtian writer of the firſt three centuries. It is more than probable that the eight books, as we have them, were not compoſed and finiſhed till after the time of Epiphanius, towards the middle, or before the end, of the fifth century. Cotelerius (Ap. Patr. Apoſt. t. i.) ſays, it is certain, that the work of the Apoſtolical Conſtitutions, in eight books, is apocryphal and pſeudepigraphal, not compoſed by the apoſtles, nor by the apoſtolic Clement. Tillemont concurs in opinion with Cotelerius. Daillé thinks, that the Conſtitutions were compoſed after the council of Nice, and before the end of the fifth century; and biſhop Pearſon ſuppoſes, that the eight books of the Conſtitutions, as we now have them, were not compoſed and finiſhed till after the time of Epiphanius. Le Clerc mentions ſome things in the Conſtitutions exceedingly unſuitable to the character of the apoſtles of Chriſt, and ſays, that they well repreſent the eccleſiaſtical diſcipline of the fourth century, but not of earlier times. He thinks, they were compoſed by ſome Arian of the fourth century; and ſeems to imagine, there may be ſome probability in the conjecture of another learned man, *viz.* Thomas Bruno or Brown, that they are the work of Leontius, biſhop of Tripoli in Lydia.

Mr. Whiſton has ventured to oppoſe the general opinion: and with ſome reaſon, much learning, and more warmth, aſſerted the Apoſtolical Conſtitutions to be one of the ſacred writings, dictated by the apoſtles in their meetings, written down from their mouths by St. Clement, and intended as a ſupplement to the New Teſtament; or, rather, as a ſcheme and ſyſtem of Chriſtian faith and polity. See his Eſſay on the "Apoſtolical Conſtitutions," and his hiſtorical preface; wherein the ſeveral ſteps he made in his fancied diſcovery are traced.

Dr. Lardner, after citing ſeveral opinions of learned men concerning this work, offers his own ſentiments in his uſual judicious and impartial manner. In his inveſtigation of its contents and authority, he obſerves, that the whole of the work, and all the ordinances in it, from beginning to end, are delivered in the name of all Chriſt's apoſtles, and as from God himſelf; and moreover, that they aſſume not only the names of the apoſtles, but alſo their characters and actions. Hence, according to the whole tenor of the work, they are rightly termed "Apoſtolical." Dr. Lardner next proceeds to inquire, both from external teſtimony and internal evidence, how far the authority claimed by theſe conſtitutions, and by the advocates of their antiquity, is well founded. To this purpoſe he obſerves, that Daillé, after having examined all the ſeveral eccleſiaſtical writers of the firſt three centuries, Barnabas, Clement of Rome, Juſtin Martyr, Athenagoras, Irenæus, Clement of Alexandria, Tertullian, Origen, Cyprian, Dionyſius, Peter of Alexandria, and ſome others, has ſhewn, with great probability, that the conſtitutions were unknown to all theſe writers. In this opinion Mr. Turner, already cited, concurs. Moreover, the conſtitutions contain a long hiſtory of Simon Magus, and an account of divers other heretics, ſuch as Cleobius, Doſitheus, the Ebionites, Cerinthus, Marc, Menander, Baſilides, Saturninus, the Nicolaitans, and Hemerobaptiſts. The evil of hereſies is ſhewn; the cauſes of them are aſcertained and enumerated; they are condemned and confuted. Nevertheleſs, no notice is taken of all this by Irenæus, Tertullian, Clement of Alexandria, or Euſebius; nor even by Epiphanius; though it would have been much more to their purpoſe. In ſhort, ſays Dr. Lardner, they could not have omitted it in their cenſures of the ancient hereſies, or in their arguments againſt them, if they had been acquainted with it; for, certainly, the expreſs authority of the apoſtles would have been of great advantage to them. As to Clement of Alexandria, though he quotes Clement of Rome, Barnabas, and other Chriſtian authors, and had many occaſions for quoting the conſtitutions, if he had been acquainted with them, yet he does not take the leaſt notice of them. Beſides, the conſtitutions abſolutely forbid the reading of heathen authors; nevertheleſs, the fore-mentioned Clement, who was himſelf a man of extenſive reading, and a great maſter of heathen learning, frequently cites in his works all ſorts of authors, and has recommended the reading of heathen authors, and the ſtudy of philoſophy; which he would not have done, if he had been acquainted with theſe conſtitutions, and had acknowledged them to be apoſtolical. Tertullian, Origen, and many more juſtify and recommend the reading of heathen compoſitions, which could not have been the caſe, if in doing this they would have violated an apoſtolical conſtitution. If, indeed, there had been a conſtitution of the Chriſtian church, which forbade the reading of ſuch books, the emperor Julian would have had no occaſion to make the ſame prohibition. In the third century a diſpute occurred about baptiſm; in which Cyprian and the African biſhops maintained againſt Stephen biſhop of Rome, that the baptiſm of heretics was null and void, and therefore that thoſe who came over from them were to be re-baptized; this controverſy is decided in the conſtitutions agreeably to the judgment of Cyprian and his colleagues; and yet it was not appealed to at that time, becauſe, probably, it was not then extant. Dionyſius, who was biſhop of Alexandria about the year 248, appears to have been altogether unacquainted with our apoſtolical conſtitutions. When a controverſy occurred about the time of keeping Eaſter, which commenced in the ſecond century, and laſted till the ſitting of the council of Nice, no appeal was made to the conſtitutions, which would have ſerved to decide the diſpute, if they had actually exiſted or had been received as apoſtolical. If an appeal be made to the writers of the fourth and the former part of the fifth century, ſuch as Gregory Nazianzen, Baſil, Chryſoſtom,

tom, the Cyrils of Jeruſalem and Alexandria, Jerom, Auguſtine, &c.; they give us no intelligence concerning the apoſtolical conſtitutions; having neither cited nor mentioned them in any of their writings. The firſt (Epiphanius excepted) who has mentioned them, as divided into ſeveral books, is the author of the imperfect work upon St. Matthew, probably a Latin writer, and plainly an Arian, who wrote ſome time after the reign of Theodoſius the Great; probably not till after the end of the fifth century. Upon the whole, the conſtitutions are deſtitute of all external evidence, that ſhould entitle them to the character of apoſtolical. As to the internal evidence, they evidently bear many marks of a later age than that of the apoſtles, and unſuitable to their character. Their manner of quoting the books of the New Teſtament does not ſuit the apoſtles, of which Dr. Lardner has given ſeveral inſtances; many things occur in theſe books, that refer to a later period than that of the apoſtles: *e. g.* they mention ſeveral heretics, as we have already obſerved, that did not appear before the end of the apoſtolical age; they alſo record various circumſtances, which ſeem to ſhew, that the reign of heatheniſm in the Roman empire had terminated, and that Chriſtians enjoyed eaſe and proſperity; and they write in a ſtyle, make uſe of terms and appellations, and refer to practices and obſervances, and offices of the church, which did not obtain till a much later period than the age of the apoſtles. Several things in the conſtitutions appear to be unworthy of the apoſtles of Chriſt; of which numerous inſtances are cited by Dr. Lardner, and alſo by Dr. Jortin, *ubi infra*. Moreover, this work is not free from inconſiſtencies, which are a diſparagement to any writings, and they uſe a mode of expreſſion that betrays a later time than is pretended. From a recital and ample illuſtration of the ſeveral particulars, above curſorily mentioned, by the two learned writers already named, and of others which our limits will not allow us to introduce, we may juſtly conclude, that the conſtitutions, in eight books, are not a work of the apoſtles, and ſince they bear their names without ſufficient authority, they muſt be referred to the claſs of impoſtures. Although the exact time when this work was compiled, cannot be determined, and learned men have offered various conjectures, Dr. Lardner inclines to the opinion of thoſe, who think that it was compoſed in the latter part of the fourth, or the beginning of the fifth century. "The author," probably, ſays Dr. Lardner, "was a biſhop of a proud and haughty ſpirit, who was fond of church-power, and loved pomp and ceremony in religious worſhip." To this purpoſe Dr. Jortin ſays, that the conſtitutions repeatedly aſſert, "that a biſhop is a God, a God upon earth, and a king, and infinitely ſuperior to a king, and ruling over rulers and kings. They command Chriſtians to give him tribute as to a king, and to reverence him as a God, and to pay him tithes and firſt-fruits, according, ſay they, to God's command; and they ſtrictly forbid Chriſtians to make any inquiry, and to take any notice, whether he diſpoſe of theſe revenues well or ill." Sentiments theſe which ſeem to have been dictated at a time when there were Chriſtian emperors.

Many learned moderns, ſays Dr. Lardner, "think the author was an Arian; but I do not concern myſelf about that: the paſſages, which have been ſuppoſed to favour Arianiſm, make a very ſmall, or no part of the preceding collections; I have no reaſon, therefore, to bring that point into the concluſion. But I preſume, that none ever ſuſpected the author to be a Homoüſian." The author of this work, whoever he was, bears teſtimony to the ſcriptures; and appears to have received all thoſe books of the New Teſtament, which were all along generally received by Chriſtians. Lardner's works, vol. iv. part 2. ch. 85. p. 320—354. Jortin's Remarks on E. H. vol. i. p. 228—278.

Constitution, in a *Phyſical Senſe*, is uſed to denote the general condition of the body, as evinced by the peculiarities in the performance of its functions: ſuch are, the peculiar pre-diſpoſition to certain diſeaſes, or liability of particular organs to diſeaſe: the varieties in digeſtion, in muſcular power and motion, in ſleep, in the appetites, &c. &c. Some marked peculiarities of conſtitution are obſerved to be accompanied with certain external characters, ſuch as a particular colour and texture of the ſkin, and of the hair, and alſo with a peculiarity of form and diſpoſition of mind; all of which have been obſerved from the earlieſt times, and divided into claſſes, which have received names, during the prevalence of the humoral pathology, which they ſtill retain, in conſequence of the neglect of this important ſtudy by modern phyſicians. See Temperament.

Constitution, in *Political Economy*, is frequently uſed in common language as ſynonymous with government; but the conſtitution and the government of a country have different meanings, and are actually diſtinguiſhed by accurate writers. "By conſtitution we mean," ſays lord Bolingbroke, in his "Diſſertation on Parties" (Works, vol. ii. p. 130.), "whenever we ſpeak with propriety and exactneſs, that aſſemblage of laws, inſtitutions, and cuſtoms, derived from certain fixed principles of reaſon, directed to certain fixed objects of public good, that compoſe the general ſyſtem, according to which the community hath agreed to be governed. Whereas by government we mean, whenever we ſpeak in the ſame manner, that particular tenor of conduct which a chief magiſtrate, and inferior magiſtrates under his direction and influence, hold in the direction of public affairs." (See Government.) Conſtitution, ſays the ſame writer, in reference to our own country, is the rule by which our princes ought to govern at all times: government is that by which they actually do govern at any particular time. One may remain immutable; the other may, and as human nature is conſtituted, muſt vary. One is the criterion by which we are to try the other; for ſurely we have a right to do ſo, ſince, if we are to live in ſubjection to the government of our kings, our kings are to govern in ſubjection to the conſtitution; and the conformity or non-conformity of their government to it preſcribes the meaſure of our ſubmiſſion to them, according to the principles of the revolution, and of our preſent ſettlement, in both of which, though ſome remote regard was had to blood, yet the preſervation of the conſtitution manifeſtly determined the community to the choice then made of the perſons who ſhould govern. In order further to evince the difference between the conſtitution and the government of a country, lord Bolingbroke obſerves that "kings may have preceded lawgivers, for ought I know, or have poſſibly been the firſt lawgivers, and government by will have been eſtabliſhed before government by conſtitution. Theſeus might reign at Athens, and Eurytion at Sparta, long before Solon gave laws to one, and Lycurgus to the other of theſe cities. Kings had governed Rome, we know, and conſuls had preceded kings, long before the decemviri compiled a body of law; and the Saxons had their monarchs before Edgar, though the Saxon laws went under his name." Theſe examples plainly prove, "that however men might ſubmit voluntarily in the primitive ſimplicity of early ages, or be ſubjected by conqueſt to a government without a conſtitution, yet they were never long in diſcovering, that (as Hooker obſerves, Eccleſ. Pol. l. 1. § 10.) "to live by one man's will became the cauſe of all men's miſery;" and therefore "they ſoon rejected the yoke, or made it ſit eaſy on their necks." By the *conſtitution* of a country, ſays archdeacon Paley (Princ. of Moral and Political Philoſ. vol. ii. chap. 7.), is meant ſo much of its law, as relates to the deſignation and form of the legiſlature; the rights and functions of the ſeveral parts of the legiſlative body; the conſtruction, office, and juriſdiction of courts of juſtice. Accordingly, the conſtitution is one principal diviſion, ſection, or title of the code of public laws; diſtinguiſhed from the reſt only by the ſuperior importance of the ſubject of which it treats: and therefore the terms *conſtitutional* and *unconſtitutional*, mean legal and illegal. In England the ſyſtem of public juriſprudence is made up of acts of parliament, of deciſions of courts of law, and of immemorial uſages; conſequently, theſe are the principles of which the Engliſh conſtitution itſelf conſiſts; the ſources from which all our knowledge of its nature and limitations is to be deduced, and the authorities to which all appeal ought to be made, and by which every conſtitutional doubt and queſtion can alone be decided. This plain and intelligible definition will ſerve to diſcover the error of thoſe writers who abſurdly confound what is conſtitutional with what is expedient, and what is unconſtitutional with any meaſure which they adjudge in any reſpect to be detrimental or dangerous; and alſo of others, who aſcribe a kind of tranſcendent authority, or myſterious ſanctity, to the conſtitution, as if it were founded in ſome higher original than that which gives force and obligation to the ordinary laws and ſtatutes of the realm, or were inviolable on any other account than its intrinſic utility. An act of parliament, in England, can never be unconſtitutional, in the ſtrict and proper acceptation of the term; but in a lower ſenſe it may, *viz.* when it militates with the ſpirit, contradicts the analogy, or defeats the proviſion of other laws, made to regulate the form of government. Moſt of thoſe, ſays our author, who treat of the Britiſh conſtitution, conſider it as a ſcheme of government formerly planned and contrived by our anceſtors, in ſome certain era of our national hiſtory, and as ſet up in purſuance of ſuch regular plan and deſign. This is intimated in the expreſſions of thoſe who ſpeak of the "principles of the conſtitution," of bringing back the conſtitution to its "firſt principles," of reſtoring it to its "original purity," or "primitive model." This, in his opinion, is an erroneous conception of the ſubject. No ſuch plan was ever formed; conſequently no ſuch firſt principles, original model, or ſtandard exiſt; that is, as he conceives, there never was a date, or point of time in our hiſtory, when the government of England was to be ſet up anew, and when it was referred to any ſingle perſon, or aſſembly, or committee, to frame a charter for the future government of the country; or when a conſtitution, ſo prepared and digeſted, was by common conſent received and eſtabliſhed. The great charter, and the bill of rights, were wiſe and ſtrenuous efforts to obtain ſecurity againſt certain abuſes of regal power, by which the ſubject had been formerly aggrieved; but theſe were, either of them, much too partial modifications of the conſtitution to give it a new original. The conſtitution of England, like that of moſt countries in Europe, hath grown out of occaſion and emergency; from the fluctuating policy of different ages; from the contentions, ſucceſſes, intereſts, and opportunities of different orders and parties of men in the community. It reſembles one of thoſe old manſions, which, inſtead of being built all at once, after a regular plan, and according to the rules of architecture, at preſent eſtabliſhed, has been reared in different ages of the art, has been altered from time to time, and has been continually receiving additions and repairs ſuited to the taſte, fortune, or conveniency of its ſucceſſive proprietors; to ſuch a building we look in vain for the elegance and proportion, for the juſt order and correſpondence of parts, which we expect in a modern edifice; and which external ſymmetry, after all, contributes much more perhaps to the amuſement of the beholder, than the accommodation of the inhabitant.

Some of our approved hiſtorians, and political writers, have diſcovered, as they conceive, the origin of the Britiſh conſtitution in the government of the Anglo-Saxons, brought hither from Germany and the northern countries. To this purpoſe, it is alleged, that the government of the northern nations, which eſtabliſhed themſelves on the ruins of Rome, was always extremely free; and that the free conſtitutions then introduced, however impaired by the encroachments of preceding princes, ſtill preſerve an air of independence and legal adminiſtration, which diſtinguiſh the European nations; and if this part of the globe maintains ſentiments of liberty, honour, equity, and valour, ſuperior to the reſt of mankind, it is ſaid to have owed theſe advantages chiefly to the ſeeds implanted by the generous barbarians of the north. The Saxons who ſubdued Britain in the 5th century, as they enjoyed great liberty in their own country, obſtinately retained that invaluable poſſeſſion in their new ſettlement; and they imported into this iſland the ſame principles of independence, which they had inherited from their anceſtors. The chieftains, (for ſuch they were, more properly than kings or princes,) who commanded them in their military expeditions, ſtill poſſeſſed a very limited authority; and as the Saxons exterminated, rather than ſubdued, the ancient inhabitants; they were indeed tranſplanted into a new territory, but preſerved, without alteration, all their civil and military inſtitutions. Their manners and cuſtoms were wholly German; and the ſame picture of a fierce and bold liberty, which is drawn by the maſterly pencil of Tacitus, will ſuit thoſe founders of the Engliſh government. The king, ſo far from being inveſted with arbitrary power, was only conſidered as the firſt among the citizens; and his authority depended more on his perſonal qualities, than on his ſtation. The Anglo-Saxons, being an independent people, little reſtrained by law, and cultivated by ſcience, were not very ſtrict in maintaining a regular ſucceſſion of their princes. Although they paid great regard to the royal family, and aſcribed to it an undiſputed ſuperiority, they either had no rule, or none that was ſteadily obſerved, in filling the vacant throne; and preſent convenience, in that emergency, was more attended to than general principles. We are not, however, to ſuppoſe, that the crown was conſidered as altogether elective; and that a regular plan was traced by the conſtitution for ſupplying, by the ſuffrages of the people, every vacancy made by the demiſe of the firſt magiſtrate. All the changes which occurred in the royal ſucceſſion, and indeed the ordinary adminiſtration of government, required the expreſs concurrence, or at leaſt the tacit acquieſcence of the people. The Anglo-Saxon monarchies were not, ſtrictly ſpeaking, either elective or hereditary; and though the deſtination of a prince might often be followed in appointing his ſucceſſor, they could not be regarded as wholly teſtamentary. The ſtates by their ſuffrage might ſometimes eſtabliſh a ſovereign; but they more frequently recognized the perſon whom they found eſtabliſhed. Our knowledge of the Anglo-Saxon hiſtory is ſo imperfect, that it is not eaſy to aſcertain all the prerogatives of the crown and privileges of the people, or to give an exact delineation of that government. It is probable, that the conſtitution might be ſomewhat different in the different kingdoms of the HEPTARCHY, and that it changed conſiderably during the courſe of ſix centuries, which elapſed from the firſt invaſion of the Saxons, till the Norman conqueſt. It appears, however, that at all times, and in all the kingdoms, there was a national council, called a *wittenagemot*, or aſſembly of the wiſe men, as the term imports, whoſe conſent was requiſite for enacting laws, and for ratifying the chief acts of public adminiſtration. The preambles to all the laws of Ethelbert, Ina, Alfred, Edward the Elder, Athelſtan, Edmund, Edgar, Ethelred, and Edward the Confeſſor; even thoſe to the laws of Canute, though a kind of conqueror, ſupply unqueſtionable proofs every where of a limited and legal government. But who were the conſtituent members of this wittenagemot, is a queſtion that has not been determined with certainty by antiquarians. (See WITTENAGEMOT.) Nevertheleſs, it is certain, that whatever we may determine concerning the wittenagemot, in whom, with the king, the legiſlature reſided, the Anglo-Saxon government, in the period preceding the Norman conqueſt, was become extremely ariſtocratical; the royal authority was very limited; and the people, even if admitted to that aſſembly, were deemed of little or no importance and conſideration. Upon the whole, notwithſtanding the ſeeming liberty, or rather licentiouſneſs, of the Anglo-Saxons, the great body even of the free citizens, in thoſe ages, really enjoyed much leſs true liberty, than where the execution of the laws is the moſt ſevere, and where ſubjects are reduced to the ſtricteſt ſubordination and dependence on the civil magiſtrate. But though the general ſtrain of the Anglo-Saxon government ſeems to have become ariſtocratical, there were ſtill conſiderable remains of the ancient democracy, which, though inſufficient to protect the loweſt of the people, without the patronage of ſome great lord, might nevertheleſs give ſecurity, and ſome degree of dignity, to the gentry or inferior nobility. The adminiſtration of juſtice, in particular, by the courts of the decennary, the hundred, and the county, was well calculated to defend general liberty, and to reſtrain the power of the nobles. The county courts, in particular, where all the freeholders were admitted, formed a wide baſis for the government, and furniſhed conſiderable checks on the ariſtocracy. However, the great influence of the lords over their ſlaves and tenants, the clientſhip of the burghers, the total want of a middle claſs of men, the extent of the monarchy, the looſe execution of the laws, and the continued diſorders and convulſions of the ſtate, ſufficiently evince, that the Anglo-Saxon government became at laſt extremely ariſtocratical; and the events, during the period immediately preceding the conqueſt, confirm this inference or conjecture. If we direct our views to a period much more ancient than that of the eſtabliſhment of the Anglo-Saxon government, and prior to the invaſion of the Romans, we ſhall find that the governments of the Britons, who were divided into many ſmall nations or tribes, though monarchical, were free, as well as thoſe of all the Celtic nations; and the common people ſeem to have enjoyed more liberty among them, than among the nations of Gaul, from whom they were deſcended.

Other writers have maintained, that the government, eſtabliſhed by the Anglo-Saxon princes, had little more affinity with the preſent conſtitution, than the general relation common indeed to all the governments founded by the northern nations, that of having a king and a body of nobility; and the ancient Saxon government is ſaid to be "left us in ſtory," (according to the ſtatement of ſir William Temple—Int. to the Hiſt. of England,) but like to many antique, broken, or defaced pictures, which may ſtill repreſent ſomething of the coſtume and faſhions of thoſe ages, though little of the true lines, proportions, or reſemblance." According to theſe writers, it is at the era of the conqueſt, that we are to look for the real foundation of the Engliſh conſtitution. From that period, ſays Spelman, "novus ſeclorum naſcitur ordo." William of Normandy, it is ſaid, having defeated Harold, and made himſelf maſter of the crown, ſubdued the ancient fabric of the Saxon legiſlation; he exterminated, or expelled, the former occupiers of lands, in order to diſtribute their poſſeſſions among his followers, and eſtabliſhed the feudal ſyſtem of government, as better adapted to his ſituation, and indeed the only one of which he poſſeſſed a competent idea. A diſtinction, however, ought to be made between the *government* of William I., which was very tyrannical, and the *conſtitution* eſtabliſhed under him in this kingdom, which was no abſolute monarchy, but an ingraftment of the feudal tenures and other cuſtoms of Normandy upon the ancient Saxon laws of Edward the Confeſſor. He more than once ſwore to maintain thoſe laws, and in the 4th year of his reign, confirmed them in parliament; yet not without great alterations, to which the whole legiſlature agreed, by a more complete introduction of the ſtrict feudal law, as it was practiſed in Normandy.

But that the liberty of the ſubject was not deſtroyed by theſe alterations to the degree which ſome writers have ſuppoſed, plainly appears, ſays lord Lyttelton, (Hiſt. Henry II. vol. i. p. 59.) by the very ſtatutes which William enacted; in one of which we find an expreſs declaration, "that all the freemen in his kingdom ſhould hold and enjoy their lands and poſſeſſions free from all unjuſt exactions and from all tallage; ſo that nothing ſhould be exacted or taken of them but their free ſervice, which they by right owed to the crown, and were bound to perform." It is further ſaid, "that this was ordained and granted to them as an hereditary right for ever, *by the common council of the kingdom;* which very remarkable ſtatute is juſtly ſtyled by a learned author (Nathanael Bacon) *the firſt Magna Charta of the Normans:* and it extended no leſs to the Engliſh than to the Normans. But it was ill obſerved by William, who frequently acted as if his will had been the only law to both nations. It muſt be alſo allowed, that by the interpoſition of many *Meſne Lords* between the crown and the people, and by many offices of judicature and military command being rendered hereditary, which under the Saxons had been either elective, or granted for a ſhort time, the conſtitution became more ariſtocratical than before, more unequally balanced, and, in ſome reſpects, more oppreſſive to the inferior orders of freemen. Nor was the condition of the nobles themſelves to be envied. For there were certain burthens annexed to their ſyſtem of fiefs, which, as they naturally grew out of that policy, were impoſed on the higheſt vaſſals as well as on the loweſt, and were more grievous than any which the Saxons had borne under their conſtitution. In proceſs of time the exceſſive power arrogated and exerciſed by the king contributed to eſtabliſh and guard the freedom of the Britiſh conſtitution; becauſe this exceſs gave riſe to the ſpirit of union and of concerted reſiſtance. Poſſeſſed of extenſive demeſnes, the king found himſelf independent; and veſted with the moſt formidable prerogatives, he cruſhed at pleaſure the moſt powerful barons in the realm. It was, therefore, only by cloſe and numerous confederacies that thoſe barons could reſiſt the tyranny of the ſovereign; and for this purpoſe they were conſtrained to aſſociate the people with themſelves, and to render them partakers of public liberty. As acts and inſtances of tyranny on the part of the conqueror were multiplied, the confederacies of the barons and of their vaſſals became more general and more vigorous; and the people at large, inſtructed and inſpirited by their leaders, ſtipulated conditions for themſelves, and inſiſted that, for the future, every individual ſhould be intitled to the protection

tion of the laws. Thus did thoſe rights, with which the lords had ſtrengthened themſelves, in order to oppoſe the tyranny of the crown, become a bulwark, which was, in time, to reſtrain their own. It was in the reign of Henry I., about forty years after the conqueſt, that the operation of theſe cauſes produced effect. As the nation had reſolved to beſtow the crown on a prince, who ſhould acquire and hold it under no other claim than a *compact* with his people, the title of the king became thus a kind of ſecurity for the liberty of the ſubject. In order to give that liberty a more ſolid and laſting eſtabliſhment, they demanded a charter; which Henry granted ſoon after his coronation, as he had ſworn to do before he was crowned. By this he reſtored the Saxon laws which were in uſe under Edward the Confeſſor, with ſuch alterations, or (as he ſtyled them) *emendations, as had been made in them by his father with the advice of his parliament;* at the ſame time *annulling all evil cuſtoms, and illegal ſanctions, by which the realm had been unjuſtly oppreſſed.* Some of thoſe grievances were ſpecified in the charter, and the redreſs of them was there expreſsly enacted. It alſo contained very conſiderable mitigations of thoſe feudal rights claimed by the king over his tenants, and by them over theirs, which were either the moſt burthenſome in their own nature, or had been made ſo by an abuſive extenſion. In ſhort, all the liberty, that could well be conſiſtent with the ſafety and intereſt of the lord in his fief, was allowed to the vaſſal by this charter, and the profits due to the former were ſettled according to a determined and moderate rule of law. "This," ſays ſir Henry Spelman, "was the original of king John's Magna Charta, containing moſt of the articles of it, either particularly expreſſed or in general, under the confirmation it gives to the laws of Edward the Confeſſor." Thoſe are therefore much miſtaken, who have ſuppoſed all the privileges granted in *Magna Charta* were *innovations* extorted by the arms of rebels from king John;—a notion which ſeems to have been firſt taken up, not ſo much out of ignorance, as from a baſe motive of adulation to ſome of our princes in later times, who, endeavouring to graſp at abſolute power, were deſirous of any pretence to conſider thoſe laws, which ſtood in their way, as violent encroachments made by the barons on the ancient rights of the crown; whereas they were in reality reſtitutions and ſanctions of ancient rights enjoyed by the nobility and people of England in former reigns;—or limitations of powers which the king had illegally and arbitrarily ſtretched beyond their due bounds. In ſome reſpects, ſays Lord Lyttelton, this charter of Henry I. was more advantageous to liberty than *Magna Charta* itſelf. Henry II. in a parliament held in London, A. D. 1155, granted a charter of liberties confirming that of his grandfather, Henry I., already mentioned. In conſequence of the legal rights eſtabliſhed by this excellent prince and the mixture of Saxon cuſtoms, which mitigated and tempered the Norman inſtitution, the conſtitution of England was the beſt feudal ſyſtem ſubſiſting, at that time, in any part of the world. The honour of eſtabliſhing in the Engliſh conſtitution itinerant judges belongs to Henry II., by whom this inſtitution was revived and regularly ſettled in the 22d year of his reign, with the advice and concurrence of his parliament held at Northampton. The extenſion of trials by juries to civil cauſes may alſo be well eſteemed a principal glory of this reign. Although ſome veſtiges of that method of trial appear among the Anglo-Saxons; yet Spelman ſays, that the uſe of trials by 12 men before the conqueſt was rare, and did not prevail in any great degree, till the reign of Henry II. (See JURY and *Grand* ASSISE.) The deſpotic reign of king John excited through the kingdom a general confederacy againſt him and conſtrained him, A. D. 1215, to ſign the famous deed, commonly called the great charter or *Magna Charta,* which either granted or ſecured very important liberties and privileges to every order of men in the kingdom; to the clergy, to the barons, and to the people. (See MAGNA *Charta.*) By this charter, the rigour of the feodal laws was greatly mitigated in favour of the lords; and conditions were alſo ſtipulated in favour of the numerous body of the people, who had concurred to obtain it, and who claimed, with ſword in hand, ſhare in that ſecurity which it was deſigned to eſtabliſh. This charter was confirmed in parliament by king Henry III., A. D. 1217, with the addition of ſome articles to prevent the oppreſſions by ſheriffs; and alſo with an additional charter of foreſts. Accordingly, theſe famous charters have ſubſiſted nearly in their original form, during many generations, as the peculiar favourites of the Engliſh nation; and they have been juſtly eſteemed as the moſt ſacred rampart to national liberty and independence. As they ſecured the rights of all orders of men, they were anxiouſly defended by all, and became the baſis, in a manner, of the Engliſh conſtitution, and a kind of original contract, which both limited the authority of the king, and enſured the conditional allegiance of his ſubjects. King Edward I. who made it a rule in his own conduct to obſerve, except on extraordinary occaſions, the privileges ſecured to the barons by the great charter, acquired a right to inſiſt upon their obſervance of the ſame charter towards their vaſſals and inferiors. By the ſtatute (25 Edw. I.) called *Confirmatio Chartarum,* (the confirmation of which was renewed eleven times in the courſe of his reign,) he directed the great charter to be allowed as the common law; all judgments contrary to it are declared void; copies of it are ordered to be ſent to all cathedral churches, and read twice a year to the people; and ſentence of excommunication is directed to be as conſtantly denounced againſt all thoſe, who by word, deed, or counſel, act contrary to it, or in any degree infringe it. He alſo, in the ſtatute *De Tallagio non Concedendo,* (24 Edw. I.) decreed, that no tax ſhould be laid, nor impoſt levied, without the joint conſent of the lords and commons. This important ſtatute, in conjunction with *Magna Charta,* forms the baſis of the Engliſh conſtitution. Under Edward II. the commons, feeling their importance, began to annex petitions to the bills by which they granted ſubſidies; and this was the dawn of their legiſlative authority. Under Edward III., they declared they would not, in future, acknowledge any law to which they had not expreſsly aſſented. Soon after this, they exerciſed a privilege, in which conſiſts, at this time, one of the great balances of the conſtitution: they impeached, and procured to be condemned, ſome of the firſt miniſters of ſtate. Under Henry IV., they refuſed to grant ſubſidies before an anſwer had been given to their petitions. In a word, the fundamental articles of our free conſtitution have been aſſerted and confirmed by a multitude of ſtatutes, (ſir Edward Coke is ſaid to reckon thirty-two,) from Edward I. to Henry IV. Then, after a long interval, they were corroborated by the *petition of right,* which was a parliamentary declaration of the liberties of the people, aſſented to by king Charles I., in the beginning of his reign. This famous act was ſoon followed by the ſtill more ample conceſſion made by that unhappy prince to his parliament, before the fatal rupture between them; and by the many ſalutary laws, particularly the *habeas corpus,* paſſed under Charles II. To theſe ſucceeded the *bill of rights,* or declaration delivered by the lords and commons to the prince and princeſs of Orange, 13th February, 1688; and afterwards enacted in parliament,

ment, when they became king and queen: which declaration terminates with theſe remarkable words: "And they do claim, demand, and inſiſt upon, all and ſingular, the premiſes, as their undoubted right and liberties." And the act of parliament itſelf (1 W. & M. ſt. 2. c. 2.) recogniſes "all and ſingular the rights and liberties, aſſerted and claimed in the ſaid declaration, to be the true, ancient, and indubitable rights of the people of this kingdom." The Révolution of 1688 may, therefore, be juſtly deemed the third grand epoch in the hiſtory of the Engliſh conſtitution. The great charter had marked out the limits within which the royal authority ought to be confined; ſome outworks were raiſed in the reign of Edward I.; but it was at the Revolution that the circumvallation was completed. "It was at this era," ſays De Lolme, "that the true principles of civil ſociety were diſtinctly ſpecified and fully eſtabliſhed. By the expulſion of a king, who had violated his oath, the doctrine of Reſiſtance, that ultimate reſource of an oppreſſed people, was confirmed beyond a doubt. By the excluſion of a family, hereditarily deſpotic, it was finally determined, that nations are not the property of kings. The principles of Paſſive Obedience, the divine and indefeaſible right of kings; in a word, the whole ſcaffolding of falſe and ſuperſtitious notions, by which the royal authority had till then been ſupported, fell to the ground: and in the room of it were ſubſtituted the more ſolid and durable foundations of the love of order, and a ſenſe of the neceſſity of civil government among mankind." The liberty of the preſs, the bulwark and guardian of a free conſtitution, was, properly ſpeaking, eſtabliſhed four years afterwards, in conſequence of the refuſal of the parliament to continue any longer the reſtrictions to which it had before been ſubject. Finally, the liberties of the Britiſh conſtitution were again aſſerted at the commencement of the laſt century, in the *act of ſettlement*, (12 & 13 W. III. c. 2.) by which the crown was limited to his preſent majeſty's illuſtrious houſe; and ſome new proviſions were added, at the ſame fortunate era, for better ſecuring our law, religion, and liberties, which the ſtatute declares to be "the birth-right of the people of England," according to the ancient doctrine of the common law.

The diſtinguiſhing excellence of the Britiſh conſtitution, which has been ſometimes called a mixed government, and ſometimes a limited monarchy, conſiſts in its being formed by a combination of the three regular ſpecies of government, *viz.* the monarchy, reſiding in the King; the ariſtocracy, in the Houſe of Lords, and the democracy or republic being repreſented by the Houſe of Commons. To this purpoſe Cicero declares himſelf of opinion, (in his Fragments, *de rep.* l. 2.) "eſſe optimè conſtitutam rempublicam, quæ ex tribus generibus illis, regali, optimo, et populari, ſit modicè confuſa." As the executive power of the laws, in the Britiſh conſtitution, is lodged in a ſingle perſon, they have all the advantages of ſtrength and diſpatch, that are to be found in the moſt abſolute monarchy: and as the legiſlature of the kingdom is entruſted to three diſtinct powers, entirely independent of each other; and as this aggregate body, actuated by different ſprings, and attentive to different intereſts, compoſes the Britiſh parliament, and has the ſupreme diſpoſal of every thing; no inconvenience can be attempted by either of the three branches, which will not, according to the theory of the conſtitution, be withſtood by one of the other two: each branch being armed with a negative power, ſufficient to repel any innovation which it ſhall think inexpedient or dangerous. Whereas, if the ſupreme power were lodged in any one of the branches ſeparately, we muſt be expoſed to the inconveniences of either abſolute monarchy, ariſtocracy, or democracy; and ſo want two of the three principal ingredients of good polity, either virtue, wiſdom, or power. If it were lodged in any two of the branches, *e.g.* in the king and houſe of lords, our laws might be providently made, and well executed, but they might not have always the good of the people in view: if lodged in the king and commons, we ſhould want that circumſpection and mediatory caution, which the wiſdom of the peers is to afford: if the ſupreme rights of legiſlature were lodged in the two houſes only, and the king had no negative on their proceedings, they might be tempted to encroach upon the royal prerogative, or perhaps to aboliſh the kingly office, and thereby weaken (if not totally deſtroy) the ſtrength of the executive power. But the conſtitutional government of this iſland is ſo admirably tempered and compounded, that nothing can endanger or hurt it, but deſtroying the equilibrium of power between one branch of the legiſlature and the reſt. For if events ſhould happen, that the independence of any one of the three ſhould be loſt, or that it ſhould become ſubſervient to the views of the other two, there would ſoon be an end of our conſtitution. The legiſlature would be changed from that, which (upon the ſuppoſition of an original contract, either actual or implied) is preſumed to have been originally ſet up, by the general conſent and fundamental act of the ſociety: and ſuch a change, however effected, is, according to Mr. Locke, (on Government, part ii. § 212.) who, ſays judge Blackſtone, perhaps carries his theory too far, at once into an entire diſſolution of the bands of government; and the people are thereby reduced to a ſtate of anarchy, with liberty to conſtitute to themſelves a new legiſlative power.

Archdeacon Paley, in his diſcuſſion of this ſubject, has ſtated the expedients by which the Britiſh conſtitution provides for the *intereſt of its ſubjects*, and for its own *preſervation*. With a view to the firſt of theſe purpoſes, it promotes the eſtabliſhment of ſalutary public laws, by rendering every citizen of the ſtate capable of becoming a member of the ſenate, and by inveſting every ſenator with the right of propounding to the deliberation of the legiſlature whatever law he pleaſes. In order to the attainment of this object, it provides ſuch repreſentatives of the people, with reſpect to their rank, condition, and character, the mode of their election, as well as the publicity and utility of their parliamentary deliberations, as ſhall be moſt likely to anſwer the end of their appointment, and to ſatisfy their conſtituents. (See COMMONS and PARLIAMENT.) For preventing deſtructive contentions for the ſupreme power, and for ſecuring the advantages of deciſion, ſecrecy, and diſpatch, which belong to the reſolutions of monarchical counſels, and other important objects, the conſtitution has committed the executive government to the adminiſtration and limited authority of our hereditary king. (See KING.) The Britiſh conſtitution has alſo guarded the ſafety of the people in the two articles of *taxation* and *puniſhment* by the moſt ſtudious precautions. With regard to *taxation*, this buſineſs is excluſively reſerved to the popular part of the conſtitution, who, it is preſumed, will not tax themſelves, nor their fellow-ſubjects, without being firſt convinced that the aids which they grant are neceſſary. The application of the public ſupplies is alſo watched with the ſame circumſpection as the aſſeſſment. The national expenditure is accounted for in the houſe of commons, and computations of the charge, appropriated to any particular purpoſe, are previouſly ſubmitted to the ſame tribunal. In the infliction of *puniſhment*, the power of the crown, and of the magiſtrate appointed by the crown, is confined by the moſt preciſe limitations: the offender's guilt, being ſubmitted to the judgment of 12 men, of his own order, and the nature and degree of the puniſhment being aſcertained by fixed laws. In order to prevent arbitrary or clandeſtine confinement, with all its injurious conſequences, the conſtitution has provided with extreme ſolicitude. The ancient writ of habeas corpus; the habeas corpus act of Charles II., and the practice and determinations of our ſovereign courts of juſtice founded upon theſe laws, afford a complete remedy for every conceivable caſe of illegal impriſonment. (See theſe articles; and ſee alſo TREASON.) The conſtitution has alſo provided for its own preſervation, by ſecuring each part of the legiſlature in the exerciſe of the powers aſſigned to it, from the encroachment of the other parts. This ſecurity is ſometimes called the *balance of the conſtitution*; and the political equilibrium, which this phraſe denotes, conſiſts in two contrivances—a balance of power, and a balance of intereſt. By the former is meant, that one part of the legiſlature poſſeſſes no power, the abuſe, or exceſs of which, is not checked by ſome antagoniſt power reſiding in another part. Thus, the power of the two houſes of parliament to frame laws, is checked by the king's negative; and, on the other hand, the application of this negative is checked by the privilege which parliament poſſeſſes, of refuſing ſupplies of money to the exigencies of the king's adminiſtration. The conſtitutional maxim "that the king can do no wrong," is balanced by another maxim, not leſs conſtitutional, "that the illegal commands of the king do not juſtify thoſe who aſſiſt, or concur, in carrying them into execution;" and alſo, "that the acts of the crown acquire not any legal force, until authenticated by the ſubſcription of ſome of its great officers." In connection with this maxim, we might mention the check which parliament holds over the adminiſtration of public affairs, in the practice of addreſſing the king, for the purpoſe of knowing by whoſe advice he reſolved upon a particular meaſure, and of puniſhing the authors of that advice for their pernicious counſel. Again, the power of the crown to direct the military force of the kingdom, is balanced by the annual neceſſity of reſorting to parliament for the maintenance and government of that force. The prerogative of the king, in declaring war, is checked by the privilege which the houſe of commons poſſeſſes, of granting or withholding ſupplies for carrying it on. The king's choice of his miniſters, is controlled by the obligation he is under of appointing thoſe men to offices in the ſtate, who are found capable of managing the affairs of his government, with the two houſes of parliament.

By the *balance of intereſt*, which accompanies and gives efficacy to the *balance of power*, is meant this, that the reſpective intereſts of the three eſtates of the empire, are ſo diſpoſed and adjuſted; that whichever of the three ſhall attempt any encroachment, the other two ſhall unite in reſiſting it. The exerciſe of arbitrary power, on the part of the king, would contract the power and privileges of the commons, degrade their dignity, and endanger their independence. It would alſo be no leſs formidable to the grandeur of the ariſtocracy than fatal to the liberty of the republic; as it would reduce the nobility from their hereditary participation in the national councils, which conſtitutes their true greatneſs, to the low and ſervile ſtate of making a part of the empty pageantry of a deſpotic court. On the other hand, if the commons ſhould entrench upon the crown, the houſe of lords, attached to the monarchy which gives them their diſtinction, would inſtantly receive an alarm from every new ſtretch of popular power. If the nobles themſelves ſhould attempt to revive the ſuperiority, which was exerciſed by their anceſtors under the feudal conſtitution, the king and the people would alike remember how the one had been inſulted, and the other enſlaved, by that barbarous tyranny. After all it ſhould be remembered, that there is a wide difference between the conſtitution, or the theory of government, and the actual exerciſe of it, nor ſhould thoſe anomalies, or irregularities, which occur in peculiar circumſtances, or periods of the public adminiſtration, be charged on the conſtitution itſelf. It is a well-known, and often cited obſervation of Monteſquieu, in reference to the Britiſh conſtitution, "as all things have an end, the ſtate we are ſpeaking of (viz. England,) will loſe its liberty, and periſh. Have not Rome, Sparta, and Carthage periſhed? It will periſh when the legiſlative powers ſhall be more corrupt than the executive." Lyttelton's Hiſt. of Hen. II. Hume's Hiſt. vol. i. ii. and iii. De Lolme's Conſtitution of England. Blackſt. Com. v. i. Paley's Principles, vol. ii. ch. 7. Rapin's Hiſt. of Eng. vol. i. Monteſq. Spirit of Laws, vol. i. b. xi. chap. 6.

CONSTRICTION, compounded of *con*, *together*; and *ſtringere*, *to tie* or *cloſe up*; the act of binding, or drawing the parts of a thing cloſe together.

CONSTRICTOR CUNNI, in *Myology*, a name applied to the ſphincter muſcle of the vagina. See GENERATION, *organs of*.

CONSTRICTOR *iſthmi faucium*, one of the muſcles belonging to the ſoft palate. See DEGLUTITION.

CONSTRICTOR *naſi*. See COMPRESSOR.

CONSTRICTOR *oris*. See ORBICULARIS *Oris*.

CONSTRICTORES PHARYNGIS. See DEGLUTITION.

CONSTRUCTION, in *Geometry*, the art or manner of drawing, or deſcribing a figure, ſcheme, the lines of a problem, or the like. The equality of the lines of ſuch a triangle, &c. is demonſtrated from their conſtruction.

CONSTRUCTION *of equations*, is the method of reducing a known equation into lines and figures; whereby the truth of the rule, canon, or equation, may be demonſtrated geometrically. Or, it is the method of finding the roots or unknown quantities of an equation, by the geometrical conſtructions of right lines or curves, according to the order or rank of the equation. The roots of any equation may be determined; that is, the equation may be conſtructed, by the interſections of a ſtraight line with another line or curve of the ſame dimenſions with thoſe of the equation to be conſtructed; for the roots of the equation are the ordinates of the curve at the points of interſection with the right line; and it is well known, that a curve may be cut by a right line in as many points as its dimenſions amount to. Thus, a *ſimple* equation will be conſtructed by the interſection of one right line with another: a quadratic equation, or an affected equation of the *ſecond* rank, by the interſections of a right line with a circle, or any of the conic ſections, which are lines of the ſecond order, and which may be cut by the right line in two points, which will give the two roots of the quadratic equation. A cubic equation may be conſtructed by the interſection of the right line with a line of the third order, &c. &c. But if, inſtead of the right line, ſome other line of a higher order be uſed; then the ſecond line, whoſe interſections with the former are to determine the roots of the equation, may be taken as many dimenſions lower as the former is taken higher. And, in general, an equation of any degree may be conſtructed by the interſections of two lines whoſe dimenſions, multiplied together, produce the dimenſion of the given equation. Thus, the interſections of a circle with the conic ſections, or of thoſe with each other, will conſtruct the biquadratic equations or thoſe of the fourth power, becauſe $2 \times 2 = 4$; and the interſections of the circle or conic ſections with a line of the third order, will conſtruct the equations of the fifth and ſixth powers, &c. &c. Hence it appears, that the method of conſtructing equations is different, according to the diverſity of equations.

To conſtruct a ſimple equation. The whole myſtery conſiſts in this, that the fractions, to which the unknown quantity is equal, be reſolved into proportional terms: the method of which will be better ſhewn by examples than it can be taught by many rules.

1. Suppoſe $x = \frac{ab}{c}$, or $cx = ab$; then will $c : a :: b : x$, to be determined by the method of finding a fourth proportional.

2. If $x = \frac{b^2}{a}$, or $ax = b^2$; then $a : b :: b : x$, a third proportional to a and b.

3. Suppoſe $x = \frac{abc}{de}$; let $d : a :: b : \frac{ab}{d}$. This fourth proportional found, being called g; $x = \frac{gc}{e}$, which is therefore found as in the firſt caſe.

4. Suppoſe $x = \frac{aa - bb}{c}$, or $cx = a^2 - b^2$. Since $aa - bb = (a + b) \times (a - b)$; $c : a + b :: a - b : x$, a fourth proportional to c, $a + b$ and $a - b$.

5. Suppoſe $x = \frac{ab}{c} + \frac{adc}{be}$. Find, as before, $g = \frac{ab}{c}$, and $f = \frac{adc}{be}$. Then will $x = g + f$ be the ſum of the lines g and f.

6. Suppoſe $x = \frac{a^2 b + bcd}{af + cg}$. Seek $\frac{cg}{a}$, and let $f + \frac{cg}{a} = h$; then will $af + cg = ah$; conſequently, $x = \frac{a^2 b + bcd}{ah}$. Thus is the preſent caſe brought to the preceding one.

7. Suppoſe $x = \frac{a^2 b - bad}{af + bc}$. Find $\frac{af}{b}$, and make $\frac{af}{b} + c = h$; then will $af + bc = bh$. Hence, $x = \frac{a^2 b - bad}{bh} = \frac{a^2 - ad}{h}$. Conſequently, $hx = a^2 - ad = a \times a - d$; and $h : a :: a - d : x$.

8. Suppoſe $x = \frac{a^2 + b^2}{c}$, or $cx = a^2 + b^2$. Conſtruct the triangle ABC (*Plate* I. *Analyſis*, *fig.* 8.) whoſe ſide $AB = a$, $BC = b$; then will $AC = \sqrt{a^2 + b^2}$. Let $AC = m$; then will $a^2 + b^2 = m^2$. And therefore $x = \frac{m^2}{c}$; conſequently, $c : m :: m : x$, a third proportional to c and m.

9. Suppoſe $x = \frac{a^2 - b^2}{c}$. On AB (*fig.* 9.) $= a$, deſcribe a ſemicircle, and therein ſet off $AC = b$. Since the triangle ACB is rectangular; $CB = \sqrt{a^2 - b^2}$. Let $CB = m$; then will $x = \frac{m^2}{c}$; conſequently, $c : m :: m : x$.

10. Suppoſe $x = \frac{a^2 b + bcd}{af + bc}$. Say, $b : a :: f : \frac{fa}{b}$; and let $\frac{fa}{b} + c = h$; then will $bc + af = bh$. Hence, $x = \frac{a^2 b + bcd}{bh} = \frac{a^2 + cd}{h}$. Find betwixt $AC = c$ (*fig.* 10.) and $CB = d$, a mean proportional $CD = \sqrt{cd}$. Let $CE = a$; then will $DE = \sqrt{a^2 + cd}$. Call this m; then will $x = \frac{m^2}{h}$; conſequently, $h : m :: m : x$.

To conſtruct a quadratic equation geometrically. Since quadratic equations may be reduced to ſimple ones, thoſe may likewiſe be conſtructed from the methods already laid down: for if the equation be pure, $x^2 = ab$; then will $a : x :: x : b$; wherefore we ſhall find $x = \sqrt{ab}$; and therefore if between $AC = a$, and $BC = b$, we find a mean proportional DC, this will be equal to x.

If the quadratic be affected, *e. g.* $x^2 + 2ax = b^2$, then form the right-angled triangle ACB (*fig.* 11.), whoſe baſe AB is a, and perpendicular BC is b; and on the centre A, with the radius AC, deſcribe the ſemicircle DCE, then will DB and DE be the two roots, *viz.* the affirmative and the negative, of the given quadratic equation. For by reſolving the quadratic, we ſhall have $x = a \pm \sqrt{b^2 + a^2} = AB \pm \sqrt{\overline{BC}^2 + \overline{AB}^2} = AB \pm \sqrt{\overline{AC}^2} = AB \pm AC$, *i. e.* DB or BE, with their proper ſigns. If the quadratic be $x^2 - 2ax = b^2$, then the conſtruction will be the ſame with that of the preceding one, $x^2 + 2ax = b^2$. But if the form be $2ax - x^2 = b^2$; form a right-angled triangle FGH (*fig.* 12), whoſe hypothenuſe FG is a, and perpendicular GH is b; then with the radius FG and centre F deſcribe a ſemicircle IGK; and IH and HK will be the two roots of the given equation $2ax - x^2 = b^2$, or $x^2 - 2ax = b^2$. Maclaurin's Algebra, part iii. chap. 2. and Simpſon's Algebra, p. 269.

To conſtruct cubic and biquadratic equations. The roots of a biquadratic equation may be determined by the interſections of two conic ſections; for the equation by which the ordinates from the four points in which theſe conic ſections may cut one another can be determined, will ariſe to four dimenſions; and the conic ſections may be aſſumed in ſuch a manner, as to make this equation coincide with any propoſed biquadratic: ſo that the ordinates from theſe four interſections will be equal to the roots of the propoſed biquadratic.

If one of the interſections of the conic ſection falls upon the axis, then one of the ordinates vaniſhes, and the equation by which theſe ordinates are determined, will then be of three dimenſions only, or a cubic; to which any propoſed cubic equation may be accommodated. So that the three remaining ordinates will be the three roots of that propoſed cubic. The conic ſections for this purpoſe ſhould be ſuch as are moſt eaſily deſcribed. The circle may be one, and the parabola is uſually aſſumed for the other.

Let APE (*fig.* 13.) be the common Apollonian parabola. Take on its axis the line AB = half of its parameter. Let C be any point in the plane of the parabola, and from it as a centre deſcribe, with any radius CP, a circle meeting the parabola in P. Let PM, CD, be perpendiculars on the axis in M and D, and let CN, parallel to the axis, meet PM in N.

Then will always $CP^2 = CN^2 + NP^2$ (47 E. 1.)

Put $CP = a$, the parameter of the parabola $= b$, $AD = c$, $DC = d$, $AM = x$, $PM = y$.

Then $CN^2 = \overline{x \overset{\backsim}{+} c}|^2$, $NP^2 = \overline{y \overset{\backsim}{+} d}|^2$; and $\overline{x \overset{\backsim}{+} c}|^2 + \overline{y \overset{\backsim}{+} d}|^2 = a^2$. ($x \backsim c$ is the difference of x and c indefinitely, whichever of the two is greateſt. That is, $x^2 \pm 2cx + c^2 + y^2 \pm dy + d^2 = a^2$. But from the nature of the parabola, $y^2 = bx$, and $x^2 = \frac{y^4}{b^2}$; ſubſtituting therefore theſe values for x^2, and x, it will be $\frac{y^4}{b^2} \pm \frac{2cy^2}{b} + y^2 \pm 2dy + c^2 + d^2 - a^2 = 0$. Or, multiplying by b^2, $y^4 \pm \overline{2bc + b^2} \times y^2 \pm 2db^2 \times y + \overline{c^2 + d^2 - a^2} \times b^2 = 0$. Which may repreſent any biquadratic equation that wants the ſecond term; ſince ſuch values may be found for a, b, c, and d, by comparing this with any propoſed biquadratic, as to make them coincide. And then the ordinates from the points, P, P, P, P, on the axis will be equal to the roots of that propoſed biquadratic. And this may be done, though the parameter of the parabola (viz. b) be given: that is, if you have a parabola already made or given, by it alone you may reſolve all biquadratic equations, and you will only need to vary the centre of your circle and its radius.

If the circle deſcribed from the centre, C, paſs through the vertex A, (*fig.* 14.) then $\text{CP}^2 = \text{CA}^2 = \text{CD}^2 + \text{AD}^2$, that is, $a^2 = d^2 + c^2$; and the laſt term of the biquadratic $(c^2 + d^2 - a^2)$ will vaniſh; therefore, dividing the reſt by y, there ariſes the cubic, $y^{3*} \pm \overline{2bc + b^2} \times y \pm 2db^2 = 0$. Let the cubic equation propoſed to be reſolved be $y^{3*} \pm py \pm r = 0$. Compare the terms of theſe two equations, and you will have $\pm 2bc + b^2 = \pm p$, and $\pm 2db^2 = \pm r$, or, $\mp c = \frac{b}{2} \mp \frac{p}{2b}$, and $d = \pm \frac{r}{2b^2}$. From which you have this conſtruction of the cubic $y^{3*} \pm py \pm r = 0$, by means of any given parabola A P E.

From the point B *take in the axis (forward, if the equation has* $-p$, *but backwards, if* p *is poſitive) the line* $\text{BD} = \frac{p}{2b}$; *then raiſe the perpendicular* $\text{DC} = \frac{r}{2b^2}$, *and from* C *deſcribe a circle paſſing through the vertex* A, *meeting the parabola in* P, *ſo ſhall the ordinate* PM *be one of the roots of the cubic* $y^{3*} \pm py \pm r = 0$.

The ordinates that ſtand on the ſame ſide of the axis with the centre C are negative or affirmative, according as the laſt term r is *negative* or *affirmative*; and thoſe ordinates have always *contrary* ſigns that ſtand on *different* ſides of the *axis*. The roots are found of the ſame value, only they have contrary ſigns, when r is poſitive as when it is negative; the ſecond term of the equation being wanting.

A cubic equation, that has all its roots equal, may be conſtructed by a circle. Let the radius O B (*fig.* 15.) = R, the ſine E F = s, G H the ſine of the arc G B or 3 B E. Then, by trigonometry, $3s - \frac{4s^3}{\text{RR}} = \text{GH}$. Draw C D parallel to A B, and put S F = c, E S = x, G H = b; then $c + x = s$, whence $3 \times \overline{c + x} - \frac{4}{\text{RR}} \times \overline{c + x}|^3 = b$; and this reduced will give

$$x^3 + 3cx^2 + 3ccx + c^3 \begin{array}{l} - \frac{3}{4}\text{RR} + \frac{1}{4}b\,\text{RR} = 0. \\ - \frac{3}{4}c\,\text{RR} \end{array}$$

Suppoſe this cubic equation to be given; *viz.* $x^3 + px^2 + qx + r = 0$. Comparing this with the former, and equating the coefficients, we ſhall have $p = 3c$, and $c = \frac{1}{3}p$; alſo $q = 3cc - \frac{3}{4}\text{RR} = \frac{1}{3}pp - \frac{3}{4}\text{RR}$; whence $\text{R} = \frac{2}{3}\sqrt{pp - 3q}$, and $r = c^2 + \frac{1}{4}b\,\text{RR} - \frac{3}{4}c\,\text{RR}$, and $b = \frac{9r - pq}{pp - 3q} + \frac{2}{3}p$. Hence we obtain the following rule for the ſolution of the given equation $x^3 + px^2 + qx + r = 0$. With the radius $\frac{2}{3}\sqrt{pp - 3q}$ deſcribe the circle B G A K (*fig.* 16.) Draw the diameter A B, and C D parallel to it at the diſtance of $\frac{1}{3}p$; above it, if it be $+p$, but below it, if it be $-p$. Draw alſo Z G parallel to A B, at the diſtance $\frac{9r - pq}{pp - 3q} + \frac{2}{3}p$, above it, if it be affirmative, or below it, if negative. Let it cut the circle in G. Take the arc $\text{BP} = \frac{1}{3}\text{BG}$, and make PQ = QK = KP. From the points P, Q, K, let fall perpendiculars upon the line C D, which will be the roots of the equation; the affirmative above the line, and the negative below it. N. B. If $3q$ be greater than pp, the equation is impoſſible; for in this caſe the equation has two impoſſible roots. Alſo, if $p = 0$, then the radius of the circle $\text{OB} = \frac{2}{3}\sqrt{-3q}$, and C D coincides with A B; and the diſtance of Z G from A B is $-\frac{3r}{q}$. And if q be affirmative, the equation is impoſſible. Theſe conſtructions are eaſy: *e.g.* 1. Let $x^3 + 9x^2 - 22x - 120 = 0$. Here the radius $\text{OB} = \frac{2}{3}\sqrt{pp - 3q} = \frac{2}{3}\sqrt{81 + 66} = 8.0829$, and $\frac{1}{3}p = 3$, the diſtance of C D above A B. And $\frac{9r - pq}{pp - 3q} + \frac{2}{3}p = \frac{-1080 + 198}{81 + 66} + \frac{2}{3} \times 6 = -6 + 6 = 0$, the diſtance of G Z from A B, which therefore coincides with it; and the arc B G, and alſo its third part is 0, and P falls on B; and making PQ = QK = KP, and letting fall perpendiculars on C D, we ſhall have PS = − 3, QT = + 4, and KT = − 10, the three roots required.

E. G. 2. Suppoſe $x^3 - 17x^2 + 82x - 120 = 0$. The radius O B (*fig.* 18.) $= \frac{2}{3}\sqrt{289 - 246} = 4.37$; $\frac{1}{3}p = -5.66$, the diſtance of C D below A B, and $\frac{9r - pq}{pp - 3q} + \frac{2}{3}p = \frac{-1080 + 1394}{289 - 246} - \frac{34}{3} = 7.302 - 11.333 = -4.031$, the diſtance of G Z below A B. Take B P the third part of B G, and making PQ = QK = KP; and meaſuring the perpendiculars upon C D, we have PS = + 4, QT = + 10, and KV = + 3, the roots of the equation.

E. G. 3. Let $y^3 - 13y + 12 = 0$. In this example $p = 0$, and therefore C D (*fig.* 19.) coincides with A B; and the radius $\text{OB} = \frac{2}{3}\sqrt{-3q} = \frac{2}{3}\sqrt{39} = 4.18$; and $\frac{-3r}{q} = \frac{-36}{-13} = 2.77$, the diſtance of Z G above A B. Take the arc $\text{BP} = \frac{1}{3}$ arc B G, and make PQ = QK = KP, and let fall perpendiculars on A B; then PS = + 1, QT = + 3, and KV = − 4, will be the roots required.

If the roots of a cubic equation, $x^3 - qx + r = 0$, be poſſible, they may be found by means of a table of coſines. Let D A C (*fig.* 20.) be an angle whoſe coſine, to the radius m, is x; in A D take $AB = m$; from B, as a centre, with the radius B A, deſcribe a circle cutting A M in C, and from C, with the ſame radius, deſcribe a circle cutting A D in D; join B C, C D, and draw B K, D M, at right angles to A M, and C L at right angles to A D. Then, the triangles B A C and B C D being iſoſceles, the angles B A C and B C A are equal, as alſo C B D and C D B; and the perpendiculars B K, C L, biſect the baſes A C, B D. Alſo, the angle $DBC = BAC + BCA = 2\,BAC$; and the angle $DCM = CAD + CDA = CAD + CBD = CAD + 2\,CAD = 3\,CAD$. Let C M, the coſine of the angle D C M to the radius m, be called c; thence, from the ſimilar triangles A B K, A C L, $AB : AK :: AC : AL$, or $m : x :: 2x : \frac{2x^2}{m} = AL$; and $AL - AB = \frac{2x^2}{m} - m = BL$; hence AD, or $AL + BL = \frac{4x^2}{m} - m$. Again, $AB : AK :: AD : AM$, or $m : x :: \frac{4x^2}{m} - m : \frac{4x^3 - m^2x}{m^2} = AM$, and $AM - AC = CM = \frac{4x^3}{m^2} - 3x = c$; therefore $4x^3 - 3m^2x = m^2c$, and $4x^3 - 3m^2x - m^2c = 0$.

Let the equation $4x^3 - 3m^2x - m^2c = 0$, or $x^3 - \frac{3m^2}{4}x - \frac{m^2c}{4} = 0$, be made to coincide with the equation $x^3 - qx + r = 0$; that is, let $\frac{3m^2}{4} = q$, and $\frac{m^2c}{4} = -r$, or $m = \sqrt{\frac{4q}{3}}$, and $c = -\frac{3r}{q}$: then, from a table of coſines, find the angle whoſe coſine is $-\frac{3r}{q}$ to the radius $\sqrt{\frac{4q}{3}}$, and the coſine of one-third of this angle, to the ſame radius, is one value of x. Hence it follows, 1. That if A be the arc whoſe coſine is c, and P the whole circumference, c is alſo the coſine of $A + P$, or $A + 2P$; therefore the coſines of $\frac{A + P}{3}$, and $\frac{A + 2P}{3}$, are alſo values of x. 2. Since the radius is greater than the coſine, $\sqrt{\frac{4q}{3}}$ is greater than $-\frac{3r}{q}$, or $\frac{4q}{3}$ is greater than $\frac{9r^2}{q^2}$; that is, $\frac{q^3}{27}$ is greater than $\frac{r^2}{4}$; therefore this ſolution can only be applied when the roots of the cubic equations are poſſible.

Vieta, in his "Canonica Recenſione affectionum geometricarum," and Ghetaldus, in his "Opus poſthumum de Reſolutione et Compoſitione Mathematica," and alſo Des Cartes, in his "Geometria," have ſhewn how to conſtruct ſimple and quadratic equations. Des Cartes has alſo ſhewn how to conſtruct cubic and biquadratic equations, by the interſection of a circle and parabola; and the ſame has been done by Baker in his "Clavis Geometrica," or "Geometrical Key." (See the article BAKER.) But the genuine foundation of all their conſtructions was firſt laid and explained by Sluſius in his "Meſolabium," pars 2. This doctrine is alſo treated of by De la Hire, in a ſmall treatiſe, entitled, "La Conſtruction des Equations Analytiques," annexed to his "Conic Sections." Sir Iſaac Newton, at the end of his "Algebra," has given the conſtruction of cubic and biquadratic equations mechanically; and alſo by the conchoid and ciſſoid, as well as the conic ſections. See alſo Dr. Halley's conſtruction of cubic and biquadratic equations, and Colſon's in the Philoſophical Tranſactions; the Marquis de l'Hoſpital "Traité Analytique des Sections Coniques," lib. iv.; and Maclaurin's "Algebra," part iii. chap. 3. However, the intent of theſe geometrical conſtructions is more readily anſwered by the method of extracting roots by converging ſeries and approximation; and therefore this mode of obtaining them is very much laid aſide.

CONSTRUCTION, or *Syntax*, in *Grammar*, denotes the arranging and connecting of the words of a ſentence, according to the rules of the language. See SYNTAX.

The conſtruction is generally more ſimple, eaſy, and direct, in the modern tongues than in the ancient: we have very few of thoſe inverſions which occaſion ſo much embarraſſment and obſcurity in the Latin: our thoughts are uſually delivered in the ſame order in which the imagination conceives them: the nominative caſe, for inſtance, always precedes the verb, and the verb goes before the oblique caſes it governs.

The Greeks and Latins, M. St. Evremont obſerves, uſually end their periods, where, in good ſenſe and reaſon, they ſhould have begun them; and the elegance of their language conſiſts, in ſome meaſure, in this capricious arrangement, or rather in this tranſpoſal and diſorder of the words.

Conſtruction is either *ſimple* or *figurative*. *Simple*, is that wherein all the terms, or parts of the diſcourſe, are placed in their natural order.

Figurative conſtruction, is that wherein we recede from this ſimplicity, and uſe certain expreſſions, ſhorter, and more elegant than nature affords.

The ſyntax, or conſtruction of words, is diſtinguiſhed into two parts, *concord* and *government*, or *regimen*.

CONSTRUCTION *of deeds and wills*, in *Law*, is regulated by ſome general rules and maxims, which have been laid down by courts of juſtice. Theſe are, 1. That the conſtruction be favourable, and as near the minds and apparent intents of the parties, as the rules of law will admit. For the maxims of law are, that "verba intentioni debent inſervire;" and "benigne interpretamur chartas propter ſimplicitatem laicorum." And therefore the conſtruction muſt alſo be reaſonable, and agreeable to common underſtanding. 2. That "quoties in verbis nulla eſt ambiguitas, ibi nulla expoſitio contra verba fienda eſt;" but that where the intention is clear, too minute a ſtreſs be not laid on the ſtrict and preciſe ſignification of words; "nam qui hæret in litera, hæret in cortice." Therefore, by a grant of a remainder a reverſion may well paſs, and *è converſo*. Another maxim of law is, that "mala grammatica non vitiat chartam;" neither falſe Engliſh nor falſe Latin will deſtroy a deed. 3. That the conſtruction be made upon the entire deed, and not merely upon disjointed parts of it. "Nam ex antecedentibus et conſequentibus fit optima interpretatio." And therefore that every part of it be (if poſſible) made to take effect; and no word but what may operate in ſome ſhape or other. "Nam verba debent intelligi cum effectu, ut res magis valeat quam pereat." 4. That the deed be taken moſt ſtrongly againſt him that is the agent or contractor, and in favour of the other party. "Verba fortius accipiuntur contra proferentem." As, if tenant in fee-ſimple grants to any one an eſtate for life, generally, it ſhall be conſtrued an eſtate for the life of the grantee. 5. That, if the words will bear two ſenſes, one agreeable to, and another

other againſt law, that ſenſe be preferred which is moſt agreeable to it. As, if tenant in tail lets a leaſe to have and to hold during life generally, it ſhall be conſtrued to be a leaſe for his own life only, for that ſtands with the law; and not for the life of the leſſee, which is beyond his power to grant. 6. That, if there be in a deed two clauſes ſo totally repugnant to each other, that they cannot ſtand together, the firſt ſhall be received, and the latter rejected. In this reſpect it differs from a will; for there, of two ſuch repugnant clauſes the latter ſhall ſtand. In both caſes, however, we ſhould endeavour to reconcile them. 7. That a deviſe be moſt favourably expounded, to purſue if poſſible the will of the deviſor, who, for want of advice or learning, may have omitted the legal or proper phraſes. Hence the law often diſpenſes with the want of words in deviſes, that are abſolutely requiſite in all other inſtruments. Thus, a fee may be conveyed without words of inheritance; and an eſtate-tail without words of procreation. By a will alſo an eſtate may paſs by mere implication, without any expreſs words to direct its courſe. With regard to a will, in this reſpect, there is no diſtinction between the rules of law and of equity; for the will, being conſidered in both courts in the light of a limitation of uſes, is conſtrued in each with equal favour and benignity, and expounded rather on its own particular circumſtances, than by any general rules of poſitive law. Blackſt. Comm. b. ii. ch. 23.

Construction *of Statutes*, comprehends the following rules: 1. In the conſtruction of remedial ſtatutes there are three points which require conſideration, *viz.* the old law, the miſchief, and the remedy; that is, how the common law ſtood at the making of the act; what the miſchief was, for which the common law did not provide; and what remedy the parliament hath provided to cure this miſchief. And it is the buſineſs of the judge ſo to conſtrue the act, as to ſuppreſs the miſchief and advance the remedy. An inſtance may be ſpecified in the reſtraining ſtat. of 13 Eliz. c. 10. By the common law, eccleſiaſtical corporations might let as long leaſes as they thought proper; the miſchief was, that they let long and unreaſonable leaſes, to the impoveriſhment of their ſucceſſors: the remedy applied by the ſtatute was the making void all leaſes by eccleſiaſtical bodies for longer terms than three lives, or 21 years. In the conſtruction of this ſtatute, it is held, that leaſes, though for a longer term, if made by a biſhop, are not void during the biſhop's continuance in his ſee; or, if made by a dean and chapter, they are not void during the continuance of the dean: for the act was made for the benefit and protection of the ſucceſſor. The miſchief is, therefore, ſufficiently ſuppreſſed, by vacating them after the determination of the intereſt of the grantors; but the leaſes, during their continuance, being not within the miſchief, are not within the remedy. 2. A ſtatute, which treats of things or perſons of an inferior rank, cannot, by any *general words*, be extended to thoſe of a ſuperior. Thus, a ſtatute, treating of "deans, prebendaries, parſons, vicars, *and others having ſpiritual promotion,*" is held not to extend to biſhops, though they have ſpiritual promotion; deans being the higheſt perſons named, and biſhops being of a ſtill higher order. 3. Penal ſtatutes muſt be conſtrued ſtrictly. Thus, by the ſtatute 14 Geo. II. c. 6. ſtealing ſheep, *or other cattle*, was made felony, by benefit of clergy: but *or other cattle* being conſidered as too looſe an expreſſion for creating a capital offence, the act was held to extend to nothing but mere ſheep. In the next ſeſſions it was therefore found neceſſary to make another ſtatute, 15 Geo. II. c. 34. extending the former to bulls, cows, oxen, ſteers, bullocks, heifers, calves, and lambs, by name. 4. Statutes againſt frauds are to be liberally and beneficially expounded. 5. One part of a ſtatute muſt be ſo conſtrued by another, that the whole may (if poſſible) ſtand: "ut res magis valeat, quam pereat." As if land be veſted in the king and his heirs by act of parliament, ſaving the right of A.; and A. has at that time a leaſe of it for three years; here A. ſhall hold it for his term of three years, and afterwards it ſhall go to the king. 6. A ſaving, totally repugnant to the body of the act, is void. If, therefore, an act of parliament veſts land in the king and his heirs, ſaving the right of all perſons whomſoever; or veſts the land of A. in the king, ſaving the right of A.: in either of theſe caſes the ſaving is totally repugnant to the body of the ſtatute, and (if good) would render the ſtatute of no effect or operation; and therefore the ſaving is void, and the land veſts abſolutely in the king. 7. Where the common law and a ſtatute differ, the common law gives place to the ſtatute; and an old ſtatute gives place to a new one: and this upon a general principle of univerſal law that "leges poſteriores priores contrarias abrogant;" conſonant to which it was laid down by a law of the Twelve Tables at Rome, that "quod populus poſtremum juſſit, id jus ratum eſto." This is to be underſtood only when the latter ſtatute is couched in negative terms, or where its matter is ſo clearly repugnant, that it neceſſarily implies a negative. But if both acts be merely affirmative, and the ſubſtance ſuch that both may ſtand together, here the latter does not repeal the former, but they ſhall both have a concurrent efficacy. 8. If a ſtatute, that repeals another, is itſelf afterwards repealed, the firſt ſtatute is hereby revived, without any formal words for that purpoſe. 9. Acts of parliament, derogatory from the power of ſubſequent parliaments, bind not. 10. Acts of parliament, that are impoſſible to be performed, are of no validity; and if out of them ariſe collaterally any abſurd conſequences, manifeſtly contradictory to common reaſon, they are, with regard to thoſe collateral conſequences, void. Some have laid down this rule more largely, alleging that acts of parliament, contrary to reaſon, are void. We may further obſerve, that equity is frequently called in to aſſiſt, to moderate, and to explain poſitive laws. Nevertheleſs, our courts of equity are only converſant in matters of property. For the freedom of our conſtitution will not allow, that in criminal caſes a power ſhould be lodged in any judge, to conſtrue the law otherwiſe than according to the letter. This caution, while it admirably protects the public liberty, can never bear hard upon individuals. A man cannot ſuffer *more* puniſhment than the law aſſigns, but he may ſuffer *leſs*. The laws cannot be ſtrained by partiality to inflict a penalty beyond what the letter will warrant; but in caſes where the letter induces any apparent hardſhip, the crown has the power to pardon. Blackſt. Com. vol. i. Introd. § 3.

CONSTRUCTION Military. This term, in its general and unlimited acceptation, extends to the conſtructing of every ſort of military work. But it is commonly and peculiarly applied to the conſtruction of the different parts of the various ſyſtems of fortification that have been delivered by writers on the ſubject in different nations and languages. And to this application of it we ſhall chiefly attend.

Fear and neceſſity muſt have firſt given riſe to works of defence or fortification, of which the object originally was ſafety or ſecurity. And although there muſt have been quarrels ever ſince there have been men, we have every reaſon to ſuppoſe that the erection of works of defence, even of the ſimpleſt kind, were ſubſequent to the fiſhing and hunting ſtate of ſociety, and even in a great meaſure to that of the paſtoral.

The diſcovery of America, which exhibited men in a much ſimpler ſtate of ſociety than any that was recorded prior to that event in hiſtory, ſacred or profane, afforded no ſpecimens or traces of ſuch works among tribes who had not formed ſome ſort of villages, and become partly, at leaſt ſtationary, by paying ſome attention to agriculture. The form and ſtructure of works of defence, varied gradually with the means and the modes of attacking them. At firſt, a ſimple row of pickets, or a ditch, with that addition, was deemed ſufficient. Afterwards, in woody countries (and all countries have been more or leſs covered with woods) an enceinte or encloſure of ſolid timber was made uſe of. Sometimes the walls round towns were raiſed with beams, earth, and ſtones. This mode of erecting them appears to have prevailed among the Gauls, in the time of Julius Cæſar, who, in the 23d chapter or ſection of his ſeventh book, "De Bello Gallico," expreſſes himſelf on the ſubject in the following words.

"Muris autem omnibus Gallicis hæc fere forma eſt. Trabes directæ perpetuæ in longitudinem, paribus intervallis, diſtantes inter ſe binos pedes, in ſolo collocantur. Eæ revincuntur introrſus, et multo aggere veſtiuntur. Ea autem, quæ diximus intervalla grandibus in fronte ſaxis effarciuntur. Iis collocatis et coagmentatis, alius inſuper ordo adjicitur, ut idem illud intervallum ſervetur, neque inter ſe contingant trabes, ſed paribus intermiſſæ ſpatiis ſingulæ ſingulis ſaxis interjectis arte contineantur: ſic deinceps omne opus contexitur dum juſta muri altitudo expleatur. Hoc quum in ſpeciem varietatemque opus deforme non eſt, alternis trabibus aut ſaxis, quæ rectis lineis ſuos ordines ſervant, tum ad utilitatem et defenſionem urbium ſummam habet opportunitatem, quod et ab incendio lapis, et ab ariete materia defendit, quæ perpetuis trabibus pedes quadragenos, plerumque introrſus revincta, neque perrumpi neque diſtrahi poteſt."

In ſome parts of Ruſſia, there are even at this day towns defended by wooden walls; and in America there are ſome works, even with ſmall baſtions, compoſed entirely of wood or timber.

In countries, however, either conſiderably cleared, or not abundantly ſupplied with timber, ſtones come chiefly, and almoſt ſolely, to be made uſe of for erecting walls round their towns and cities. Theſe walls were at firſt ſimple ſtone encloſures, of a ſufficient height to prevent ſurpriſes, and thickneſs at top for three or four men to walk a-breaſt. But having no flanking defences, they occaſioned dead or unſeen parts throughout their whole extent; by which means the aſſailants, as ſoon as they got near the foot of them, were almoſt as much ſcreened or covered from the view of thoſe who defended them, as they on the other hand were from theirs. To remedy this inconvenience and defect, openings were made on the top of ſuch a wall, and loopholes. This contrivance, however, did not afford a complete remedy, or entirely remove the defect. For the oppoſite ſides of every adjacent two of theſe openings and loopholes, which were wider within than without, produced, formed with the front of the wall a triangular ſpace, that could not be ſeen or commanded from them. To remove this defect, ſquare towers were added to the wall at diſtances from one another, ſuited to the miſſile weapons then in uſe, with one face of each looking towards the field. This mode, however, of encloſing towns, was ſtill found to be imperfect and defective, as the face of each of thoſe towers that fronted the field, could not be ſeen from any other part, and of courſe could not be defended. Round towers were therefore introduced inſtead of them, as creating fewer dead parts, and as being better calculated for reſiſting battering engines. This method was practiſed a long time, and would, in all human probability, have continued in uſe had it not been for the invention of gun-powder, which changed the mode of attacking places, and of courſe rendered alterations in that of defending them neceſſary. Even after the application of that powerful and inflammable ſubſtance to military purpoſes, bulwarks, or large baſtions, of a round form, continued for a long time in uſe. Moſt of theſe have been either taken down, or changed into angular ones. But ſeveral ſtill remain, and are to be ſeen in different parts of Europe.

The inteſtine wars which harraſſed Italy for a length of time, taught the Italians experience in war, and the neceſſity of attending to every thing that contributed to improve the art of defence. They were accordingly the firſt people in Europe who fixed the idea of modern fortification, and reduced it to a ſort of ſyſtem. Unaccuſtomed then, however, to the effects of ſhells, and a numerous artillery, they confined their improvements chiefly to the covering of two guns in each flank, for diſputing the paſſage of the ditch.

The war, which afterwards broke out in the Low Countries, and continued during eighty years with an extraordinary degree of valour and obſtinacy, and a deſtruction of the human race, of which there are but few examples, contributed a good deal to the advancement of this ſcience. The Dutch, who alone, and unſupported, had to oppoſe for a long time the whole preſſure of a power ſo formidable as that of Spain then was, made great progreſs in the attack and defence of places. And it is from that time that we ought to date the epoch of the ſuperiority which the former of theſe has acquired over the latter.

The following is Errard's method of conſtruction. He fortifies inwards; and his line of defence is raſant in all figures. He makes his flank from the ſquare, up to the octagon, incluſive, perpendicular to the face of the baſtion. But, in all other polygons, he makes it perpendicular to the curtain.

The flanked angle, or ſaliant angle of the baſtion, is, in the ſquare, equal to ſixty degrees, in the pentagon, to eighty, and in all other polygons, to ninety degrees.

For inſtance, let AB (*Plate* V. *Fortification, fig.* 1.) be the ſide of a hexagon, of which O is the centre. Draw the radii A O, B O, at the extremities A, B, of the exterior ſide A B, make the angles O A F, O B E, each equal to forty-five degrees. From the points A, B, draw right lines A E, B F, biſecting theſe angles, and meeting B E, A F, in the points E, F. Then theſe laſt-mentioned points E, F, will be the terminations of the curtain E F, of the lines of defence A F, B E, and of the flanks E C, F D, which in all figures, up to the octagon incluſive, are by this conſtruction perpendicular to A F, B E, the lines of defence, but in all other polygons to E F, the curtain. If the ſame conſtruction be made on each of the other ſides of the hexagon, it will be fortified. And if from C, D, the angles of the epaules or ſhoulders, right lines be drawn parallel to the raſant lines, or lines of defence A F, B E, we get the counterſcarp of the ditch. On the inſide he makes a rampart equal in breadth to the length of one of the flanks.

Since the line A B, in the preceding figure, is ſuppoſed to repreſent the ſide of a regular hexagon inſcribed in a circle, the angle A O B of the centre is equal to 60 degrees, the angle A B K of the polygon is equal to 120 degrees; the flanked angles, or angles of the baſtions L A C,

D L M.

D B M, are each of them equal to a right one, or 90 degrees. The angles of the epaules or ſhoulders A C E, B D F, are alſo each of them equal to a right angle. The angle *diminué* A F G, or B E H, or the angle A B E, or B A F, formed by the exterior ſide, and either line of defence being equal to the difference between 60 and 45 degrees, is of courſe equal to 15 degrees. The angle C E F, or D F E of the flank, is equal to 75 degrees, and the flanking angle C N D, is equal to 150 degrees. But ſince the angle C A E, which is half the flanked angle, or angle of the baſtion, is equal to 45 degrees, and is by conſtruction biſected by the right line A E, each of the angles C A E, E A G is equal to 22° 30′. And the angle A E C, the complement of C A E to 90°, is conſequently equal to 67° 30′. The angle A E G is therefore equal to 37° 30′, the angle A E F to 142° 30′; the angle A G F to 120 degrees, and the angle E A B to 37° 30′. Alſo the angle A E B is equal to 127° 30′.

Thus then all the neceſſary angles are known for calculating the different parts of the conſtruction. For the exterior ſide A B being given, the line of defence A F or B E is eaſily found by means of the triangle A F B, or the triangle A E B, by the following analogies.

As the ſine of the angle A F B
Is to the ſine of the angle A B F,
So is the ſide A B
To the ſide A F.
As the ſine of the angle A E B
Is to the ſine of the angle B A E,
So is the exterior ſide A B
To the line of defence B E.

And the right line A E, or its equal B F, is found by the following analogy.

As the ſine of the angle A E B
Is to the ſine of the angle A B E,
So is the exterior ſide A B
To the right line A E or B F.

And as the angle A C E is a right one, we get the face A C of the baſtion, and the flank C E, by means of A E, and the following analogies.

As radius
Is to the ſine of the angle A E C,
So is the right line A E, or its equal B F,
To A C, the face of the baſtion, or its equal B D.
And,
As radius
Is to the ſine of the angle C A E,
So is the right line A E, or its equal B F,
To the flank C E, or its equal D F.

The perpendicular to the exterior ſide A B, or the rectilinear diſtance from the middle of it, to the point N, the interſection of the raſant lines, or lines of defence, is determined by this analogy.

As radius
Is to the tangent of the angle B A N, or A B N,
So is half the exterior A B
To the perpendicular diſtance from the middle thereof, to the point N.

By means of the flank, the curtain is found by the following analogy.

As radius
Is to the ſecant of the angle C E F, or D F E,
So is the flank C E, or D F,
To the curtain E F.

And the capital A G of the baſtion is found by this analogy.

As the ſine of the angle A G E
Is to the ſine of the angle A E G,
So is the right line A E
To the capital A G of the baſtion.

In like manner, the demi-gorge E G, or F H, is found by the following analogy.

As the ſine of the angle A G E
Is to the ſine of the angle E A G,
So is the right line A E, or its equal B F.
To the demi-gorge G E, or its equal F H.

The calculation of theſe different parts will be ſimilar when the flank is perpendicular to the curtain, inſtead of the lines of defence as in polygons above an octagon, which is effected by taking the right lines N C, N D, equal, reſpectively, to the lines N E, N F. The flanks then are longer and better.

This author aſſigns no reaſon drawn either from the nature of the polygons, or their capability of being embraced or defended for the length of his perpendicular or the magnitude of the angle formed by an exterior ſide, and a line of defence. And, as in all polygons, from the hexagon upwards, the flanked angle or ſaliant angle of the baſtion, is the ſame, or equal to 90 degrees; his conſtruction in all polygons, above an octagon, gives this perpendicular or angle much greater than it ought to be. Thus, in a decagon, it gives this angle equal to $\frac{180^\circ - \frac{360^\circ}{10} - 90^\circ}{2} = 27^\circ$; whereas, it ought but very little to exceed $22\frac{1}{2}^\circ$.

In a dodecagon is given this angle $= \frac{180^\circ - \frac{360^\circ}{12} - 90^\circ}{2} = 30^\circ$. ; whereas it ought only to be about 24°. And this conſtruction on part of a right line, which may be regarded as a polygon of an infinite or rather indefinite number of ſides, gives this angle equal to 45 degrees, and the flanking angles formed by the interſections of the lines of defence, equal each to 90 degrees. The lines of defence in this caſe exactly correſpond with Montalambert's conſtruction in his "Fortification Perpendiculaire."

As in this conſtruction the angle *diminué*, or the angle formed by an exterior ſide and a line of defence increaſes faſt in magnitude, as the number of the ſides of the polygon increaſe, being in the dodecagon twice as great as it is in the hexagon, the lengths of the curtains decreaſe and the faces of the baſtions increaſe greatly beyond their juſt proportions, which is a material defect; ſince the faces, which are the weakeſt parts, being defended reſpectively, only on one ſide by a ſingle flank, are thereby augmented, and the curtains, which are the ſtrongeſt, being defended each on both ſides, or by two flanks, are diminiſhed.

His mode of placing the flanks in figures up to the octagon incluſive at right angles to the lines of defence, and in other polygons perpendicular to the curtains, though it certainly ſecures them well againſt the enemies' batteries, and renders them fit for defending the gates and curtains, (which, however, by their nearneſs to the flanks, are naturally beſt ſecured), does not enable them to diſcover the enemies' batteries ſufficiently to defend the counterſcarp, and prevent them from advancing their works to it, a circumſtance which affords great advantage to the beſiegers. And if orillons be made in flanks, ſo placed, the covered flanks would be ſo hid, that they could ſcarcely ſee the ditch throughout its whole width, and the merlons from their angles towards the field being very acute, would eaſily be ruined by the enemies' batteries and rendered uſeleſs. Flanks ought to be placed perpendicularly, or at leaſt very nearly ſo to the lines of defence. For when an enemy once makes a lodgment on the counterſcarp, he will diſcover them whether they be ſo placed or not. And if flanks be diſcovered, they alſo diſcover, and being either reveted or demi-reveted and formed of earth that is well ſettled, they are by no means ſo eaſily ruined as the batteries of the beſiegers, which are formed of gabions and newly raiſed earth.

Count Pagan's method of conſtruction on a polygon, (*fig.* 2.) is widely different from that of Errard, and alſo much preferable. For inſtead of making the angle of the flank acute in the octagon and figures of a ſmaller number of ſides, and only equal to a right one in any polygon of a greater number of ſides, as Errard does, he makes it obtuſe and places his flanks perpendicularly to the lines of defence, in order that they may diſcover more ground, and the better raſe and defend the faces of the baſtions, which are the moſt ſaliant and weakeſt parts of the body of the place and are firſt attacked, breaches being commonly made in them. This ingenious author makes his lines of defence like Errard's, always raſant, but does not like him make 90 degrees the maximum of his flanked angle, or angle of his baſtion.

He delivers conſtructions for three ſorts of fortifications, namely, the great, the mean, and the little. He fortifies or conſtructs inwards, and in the great fortification makes the exterior ſide equal to 200 toiſes, in the mean equal to 180 toiſes, and in the little equal to 160 toiſes. He allows 60 toiſes to each face of a baſtion in the great, 55 in the mean, and 50 in the little, in all figures above a ſquare. He makes the perpendicular to the exterior ſide in the great fortification in all figures, except the ſquare where it is 27 toiſes, equal to 30 toiſes; in the mean equal to 24 toiſes; and in the little equal to 21.

The dimenſions of theſe principal lines in theſe three kinds of fortification, are contained in the following Table.

	Great Fortification.		*Mean.*		*Little.*	
	Square.	In all other Polygons.	Square.	In all other Polygons.	Square.	In all other Polygons.
Exterior Sides.	200	200	180	180	160	160

Facesofbaſtions	60	60	55	55	45	50

Suppoſing then the exterior ſide A B, (ſee the figure,) equal to 200 toiſes in the great, to 180 in the mean, and to 160 in the little, biſect it in the point C. In C O, which is perpendicular to A B, take C D equal to 30 toiſes, in all regular figures of a greater number of ſides than four. Through the point D, draw the lines of defence A D H, B D G, on which take A E and B F, each equal to 60 toiſes in the great fortification, to 55 in the mean, and to 50 in the little. Then draw the flanks E G, F H, perpendicularly to the raſant lines or lines of defence B G, A H, and form the curtain by joining the points G, H. This is Count Pagan's conſtruction, without orillons and retired flanks.

The figure is a regular hexagon, ſuppoſed to have each of its ſides equal to 180 toiſes, as in his mean fortification. The angle A O B of the centre is therefore equal to 60 degrees, and the angle of the polygon to 120. A C, or B C, is equal to 90 toiſes, the perpendicular C D is equal to 30, and the face A E, or B F, to 55 by conſtruction.

Now by means of theſe lines and angles, the others are eaſily found. And in the firſt place, the angle *diminué* C A D, or the angle formed by the exterior ſide A B, and the line of defence A H, is formed by the following analogy.

As A C, equal to 90 toiſes,
Is to C D, equal to 30 toiſes,
So is radius
To the tangent of the angle $C A D = 18° 26' 6''$ very nearly. If this angle be taken from 60 degrees, half the angle of the polygon, we get the angle O A H, or M A E, equal to $41° 33' 54''$. But this is equal to half the ſaliant angle of the baſtion, wherefore the whole flanked angle or angle of the baſtion is equal to $83° 7' 48''$. And the flanking angle A D B, being equal to the exceſs of 180 degrees above twice the angle *diminué*, is evidently equal to $143° 7' 48''$.

The tenaille A D, being equal to $\sqrt{\overline{AC}^2 + \overline{CD}^2}$, is $= \sqrt{9000} = 10\sqrt{90} = 94.868329805$ nearly. Or it is found by this analogy.

As radius
Is to the ſecant of the angle *diminué* C A D,
So is A C, half the exterior ſide A B,
To the tenaille A D.

If from this there be taken the face A E, which is equal by conſtruction to 55 toiſes, we get the right line D E, and the following analogy for the flank E G.

As radius
Is to the ſine of double the angle *diminué* C A D,
So is the right line D E
To the flank E G.

And as the angle A E G of the epaule or ſhoulder is always, in regular conſtruction, equal to twice the angle *diminué* C A D, and the angle E G B formed by the flank and line of defence, the angle D E G is known, and D G is aſcertained by the following analogy.

As radius
Is to the ſine of the angle D E G,
So is the right line D E
To the right line D G.

The angle E G H of the flank, is in this conſtruction equal to 90 degrees, together with the angle *diminué*, or the angle formed by the exterior ſide, and one of the lines of defence.

The complement, D G, or D H, being thus found, the curtain G H is aſcertained by the following analogy.

As the ſine of the angle *diminué* D G H
Is to the ſine of double the ſaid angle,
So is the complement D G
To the curtain G H.

The lengthened curtain M H, or G N, is determined by the following analogy.

As the ſine of half the angle of the polygon
Is to the ſine of half the flanked angle,
So is the raſant line, or line of defence A H,
To the lengthened curtain M H. From which, and the curtain G H, the inward or interior ſide M N is immediately obtained.

And the capital A M is aſcertained by this analogy.

As the ſine of half the angle of the polygon
Is to the ſine of the angle *diminué*,
So is the raſant line, or line of defence A H,
To the capital A M of the baſtion.

It is manifeſt from the foregoing table, that the perpendicular in this learned and judicious author's great fortification, ſubtends in the ſquare an angle of about $15° 6' 34''$ nearly, and in all other regular figures of about $16° 41' 57''$ nearly; that in his mean fortification it ſubtends in the ſquare an angle of about 14° 55′ 53″, and in all other regular figures an angle of about 18° 26′ 6′; and that in his little fortification, it ſubtends in the ſquare an angle of about 14° 42′ 30″, and in all other regular figures an angle of about 20° 33′ 22″.

For his caſemates or retired batteries and orillons, he biſects his flanks, leaving one-half of each adjoining the epaule or ſhoulder for its orillon. The firſt flank or battery on the other half is retired five toiſes behind the orillon, and is two toiſes above the level of the ditch; the ſecond is retired ſeven toiſes within the firſt, and is four toiſes above the level of the ditch; and the third is retired ſeven toiſes behind the ſecond, and is ſix toiſes above the level of the ditch, being as high as the rampart, which is three toiſes above the level of the field, or terre-plain of the place, as the bottom of the ditch is three toiſes below it. Theſe are formed by continuing the lines of defence into the baſtions, and drawing lines parallel to theſe continuations from the points biſecting the flanks.

He makes within each of his baſtions a ſort of ſmaller baſtion, or a cavalier in the form of one, having its faces parallel to thoſe of the baſtion and 13 toiſes diſtant from them, which ſerves as a retrenchment. The great ditch is 16 toiſes wide, and its counterſcarp is parallel to the faces of the baſtions or to the lines of defence. The capital of each of the ravelins, which he places on the re-entering angles of the counterſcarp in ſuch a manner as to be defended by the faces of the baſtions and the counter-guards before them, is equal to 50 toiſes, and its faces are drawn to the ſhoulders. The demi-gorges of the redoubt within the ravelin are each equal to 15 toiſes, and the faces of it are parallel to thoſe of the ravelin itſelf. The ditch of the ravelin is 12 toiſes wide, and that of the redoubt 6. The ſaliant angle of each counter-guard is 40 toiſes diſtant from that of the baſtion which it covers, and this work is from 9 to 10 toiſes broad at its extremities. The ditch before it is 12 toiſes wide. The covert-way is 4 toiſes wide, and the faces of the places of arms are each 8 toiſes long, and parallel to the oppoſite counterſcarp.

The flanks, curtain, and other lines in this conſtruction found above by means of ſines, tangents, and ſecants, may be aſcertained without any logarithmic table, in the following manner.

Since the tenaille A D is $= 10\sqrt{90}$ toiſes $= 30\sqrt{10}$ toiſes, and A C is $= 90$ toiſes by hypotheſis, and C D is $= 30$ toiſes, by conſtruction, or $= \frac{AC}{3}$, we have $AD : AC :: \sqrt{10} : 3$, and $AD : CD :: \sqrt{10} : 1$. But $AD : AC :: AE$ (55 toiſes by conſtruction) : the exceſs of A C above one half of E F, which exceſs is therefore equal to $\frac{3 \times 55}{\sqrt{10}}$ toiſes, and its double, which is the exceſs of A B above E F, is of courſe equal to $\frac{330}{\sqrt{10}}$ toiſes, or to $33\sqrt{10}$ toiſes; conſequently E F is equal to $180 - 33\sqrt{10}$ toiſes; but $AD : CD :: EF : FH$, and $AD : AC :: EF : EH$; wherefore the flank F H is equal to $\frac{180-33\sqrt{10}}{\sqrt{10}}$ toiſes $= 18\sqrt{10}-33$ toiſes; and E H is equal to $\frac{540-99\sqrt{10}}{\sqrt{10}}$ toiſes $= 54\sqrt{10}-99$ toiſes. And ſince E D is $= AD - AE = 30\sqrt{10} - 55$ toiſes; we get D H equal to $24\sqrt{10} - 44$ toiſes. But $AD : AB :: DH : GH$, which is therefore equal to $\frac{24\sqrt{10}-44}{\sqrt{10}} \times 6$ toiſes $= \frac{144\sqrt{10}-264}{\sqrt{10}}$ toiſes; and D I, which is equal to a ſixth part of G H is equal to $\frac{24\sqrt{10}-44}{\sqrt{10}}$ toiſes. Conſequently C I is equal to $\frac{54\sqrt{10}-44}{\sqrt{10}}$ toiſes. And $OC : CI :: OA$: the capital A M of the baſtion. Count Pagan's flank, in his mean fortification, being to the perpendicular, as $18\sqrt{10}-33$ to 30, is upwards of 5 toiſes leſs than it, which is certainly too great a difference.

This learned and judicious author, whom the principal fortifiers ſince his time, particularly Vauban, have very much followed, conſidering that the flanks, ramparts, and ditches, were the works that contributed moſt powerfully towards the defence of the body of a place, and the retarding of the approaches of an enemy to it, made the demi-gorges of his baſtions large, in order to have three flanks or batteries on each of them, ſufficiently long for placing four pieces of cannon in, reſpectively. Three of theſe, in each of the ſaid three flanks, are, by his conſtruction, ſo well covered from the counter-batteries of the beſiegers, that they cannot eaſily be damaged by them. And the beſiegers, on approaching the breaches, and attempting to make lodgments in the ruins of them, muſt ſuffer greatly from the guns ſo covered in theſe retired flanks, as they are then fired on by them, de revers, or in the rear.

Though his diviſion of fortification, into great, mean, and little, ſeems not to be of much uſe, or moment, he muſt certainly be allowed to be the firſt writer on the ſubject that gave the true poſition to his flanks, making them perpendicular to the lines of defence. His mean fortification appears to be preferable to the great, as it does not make the lines of defence too long for muſquet-ſhot. The poſition of the flanks, and great length, he gives to the faces of his baſtions, render his demi-gorges long enough to afford a ſufficiency of room for his retired flanks.

The two ditches, with the two ramparts, that he makes, are well calculated for obſtructing and retarding the enemies' paſſage of the ditch, for depriving them of the uſe of fourneaux, and for preventing them from lodging themſelves on the ruins of the breaches. For when the beſiegers have even paſſed the main ditch, and taken the firſt rampart, they will find themſelves expoſed in the ſecond ditch to the beſieged's fire on all ſides, and liable to be deſtroyed by ſhells, handgrenades, fourneaux, mines, &c.

By giving one-half of his flank to the orillon, he covers his retired batteries extremely well. The ditch is very well defended from the flanks, which being perpendicular to the lines of defence, look fully along the faces of the oppoſite baſtions.

It muſt be obſerved, however, that though the poſition of his flanks be good, they are too ſmall, particularly in polygons of a conſiderable number of ſides, being a good deal ſhorter than the perpendiculars to the exterior ſides; whereas they ſhould be equal, or nearly equal to them, as perpendiculars to the exterior ſides of polygons were firſt introduced into conſtruction for the ſole purpoſe of obtaining flanking defences. This is in a great meaſure occaſioned by his making the faces of his baſtions too long, which he was probably led to do from a deſire of obtaining three retired batteries in each flank. The face of the baſtion is equal to the $\frac{11}{35}$th part of the exterior ſide, whereas it may with confidence be aſſerted, that it ought not to exceed a fourth. For the faces of the baſtions are moſt ſaliant, and conſequently the tendereſt part of the body of the place. They are always firſt attacked, and in them the breaches are conſtantly made. But when they are very long, the beſiegers can make large breaches in them, which is a great advantage to them, and a no leſs diſadvantage to the beſieged.

The retrenched baſtion, or redoubt in form of one within the baſtion, muſt increaſe the expence at leaſt one-third. The ditch before it is but ill defended, as there are no tenailles for that purpoſe. And as it is hollow or empty, it may be taken as eaſily as the main baſtion, by means of a ſecond mine, and thereby occaſion the loſs of the place, eſpecially as no retrenchment can be raiſed within it to enable the beſieged to capitulate with more advantage.

His retired flanks, or batteries, appear to be too near to one another, being only ſeven toiſes diſtant from outline to outline.

He makes no traverſes. But this cannot be imputed to him as either an overſight or fault, as firing *en ricochet* was not known in his time. By giving the ſame length of perpendicular to the exterior ſides of all figures of a greater number of ſides than four, he makes the flanked angle, or angle of the baſtion in a polygon of a conſiderable number of ſides, very obtuſe. This angle begins to become obtuſe in the hexagon, and by his conſtruction on part of a right line, it is no leſs an angle than one of $143^\circ\ 7'\ 48''$.

He aſſigns no reaſon whatſoever for the length of his perpendicular, derived from the properties of different polygons, or their relative degree of importance and capability of defence, nor for his giving the ſame perpendicular in all regular figures of a greater number of ſides than four. His perpendiculars are mere arbitrary aſſumptions, like thoſe of all other authors, who have written on fortification ſince his time. The truth however is, that every regular figure has a perpendicular of its own, which is different from that of any other, of a preciſe and determinate length, and bearing a given ratio to the exterior ſide.

Mr. Blondel's method of conſtruction is as follows:

Like Count Pagan he fortifies inwards, but inſtead of the perpendicular he begins with the angle *diminué*, or the angle formed by an exterior ſide, and a line of defence. This angle he determines by taking a right angle, or 90 degrees from the angle of the polygon, and adding 15 degrees to a third part of the remainder. Thus, if n denote the number of the ſides of a regular figure, the angle of the polygon, or the angle contained by two of its ſides, will be equal to $180^\circ - \frac{360^\circ}{n}$, and his angle *diminué* will of courſe be equal to $30^\circ - \frac{120^\circ}{n} + 15^\circ$ or $45^\circ - \frac{120^\circ}{n}$, which gives 15° for it in the ſquare, 21° in the pentagon, 25° in a hexagon, and in his conſtruction on part of a right line 45°, which then makes the perpendicular equal to half the exterior ſide. This expreſſion for his angle *diminué*, as is evident by inſpection, is always equal to the exceſs of 45° above 120° divided by the number of the ſides of the figure; wherefore it is always found without any reference whatſoever to the angle of the polygon, by dividing 120° by the number of the ſides of the figure, and ſubtracting the quotient from 45°. And ſince the angle of the centre, or the angle ſubtended by one of the ſides of the figure, is equal to $\frac{360^\circ}{n}$, this angle *diminué* is had by taking from 45 degrees a third part of the angle of the centre.

His angle *diminué* gives the angle of the baſtion, or flanked angle, in a ſquare equal to 60 degrees, in a pentagon equal to 66 degrees, in a hexagon equal to 70 degrees, and in a conſtruction on part of a right line equal to 90 degrees.

The flanking angle, or the angle formed by the lines of defence, is in the ſquare, equal to 150 degrees, in the pentagon, to 138, in the hexagon, to 130, and in a conſtruction on part of a right line, to 90 degrees.

He ſuppoſes two ſorts of fortification, *viz.* the great, in which he makes the exterior ſide equal to 200 toiſes in all polygons; his line of defence equal to ſeven tenths of the exterior ſide, or 140 toiſes; and the face of his baſtion equal to half the tenaille, or line between a flanked angle and the interſection of the lines of defence; and the little, in which he makes the exterior ſide in every figure equal to 170 toiſes, the line of defence equal to ſeven tenths of this, or to 119 or 120 toiſes, and the face of the baſtion equal to half the tenaille, his conſtruction in both being the ſame.

Thus for inſtance, let A B (*fig.* 3.) be the ſide of a hexagon. At its extremities A, B, make the angles *diminué* A B G, B A G, each equal to 25 degrees, the exceſs of 45 degrees above a third part of A M B the angle of the centre. On A G, B G produced take A F, B E for the lines of defence, each equal to ſeven tenths of A B the exterior ſide. Biſect the tenailles A G, B G, in the points C, D, to get the faces A C, B D, draw the flanks C E, D F, and form the curtain by drawing E F.

Mr. Blondel takes on each flank 10 toiſes for his ſquare orillon, employing the reſt of it as a covered flank, which he keeps retired five or ſix toiſes inwards, as high as the heptagon; on higher polygons from 10 to 12 toiſes, in order to lengthen the curtains; and to obtain curtains in conſtructions, which being made on a ſtraight line, or very high polygons, have none, or very ſhort ones, he retires his flank as much as 20 toiſes, that he may have a curtain upwards of 20 toiſes long. For by his conſtruction on a right line, where the angle *diminué* is 45 degrees, the tenaille is upwards of ſeven tenths of the exterior ſide. The retirade of the flank is meaſured on a right line, drawn from the angle of the oppoſite baſtion, to the point terminating the ten toiſes, ſet off from the epaule on the flank for the orillon. Like Count Pagan, he makes three retired batteries in each flank within the caſemate, allowing three toiſes for the breadth of the parapet in each, and five for its platform, or eight toiſes from the outline of one battery to that of another. The loweſt of theſe retired flanks is from nine to twelve feet above the bottom of the ditch, the ſecond from 18 to 24, and the third, or higheſt, from 27 to 36 feet, being level with the rampart. Theſe three flanks are terminated towards the demi-gorge upon the line of defence produced, and towards the orillon, on the line drawn from the angle of the oppoſite baſtion, through the end of the ſame orillon. The parapet of the loweſt flank is nine or ten feet high, that of the middle one ſix or ſeven, and that of the third, or higheſt one, $3\frac{1}{2}$. Thoſe of the loweſt, and middle one, muſt of courſe have embraſures in them.

As there is a great deal of ſpace between the two high flanks in each baſtion, he makes a cavalier in it, having its faces parallel to the flanks, and each of them capable of holding twelve pieces of cannon at leaſt. Theſe cavaliers and retired flanks muſt be made with the earth taken from the great ditch, of which the width is equal to the length of one of the flanks. The re-entering angle of the counterſcarp is therefore oppoſite to and nearly about the middle of the exterior ſide.

This author places a counter-guard in front of each baſtion, with its faces parallel to thoſe of the ſame compoſed entirely of maſonry without any earth, and every where countermined. Its breadth or thickneſs is only from 3 to 4 toiſes, including its parapet, which is from 8 to 10 feet thick. It is erected in the great ditch 10 or 12 toiſes diſtant from the counterſcarp, which diſtance therefrom forms its ditch. The principal object in erecting this counter-guard is to conceal from the enemies' view the low flanks oppoſite to it, whilſt its narrowneſs or ſmall breadth puts it out of his power to place his guns in after he has taken it.

The ſaliant angle of his ravelin is determined by the interſection of two arcs, deſcribed from the ſhoulders of the two adjoining baſtions, with a radius equal to the diſtance between them. Its faces produced meet thoſe of the baſtions about 6 toiſes from the ſhoulders and are bounded on the lines or faces of the counter-guards produced, which alſo determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toiſes broad, and that it may be the better defended, Mr. Blondel takes, in the face of the baſtion, a ſpace equal to this breadth, commencing ſix toiſes from the ſhoulder, in which he makes a low battery of 4 or 5 feet high, and another on the inſide of the ſame height with the parapet of the place, and retired about 7 toiſes within the face.

The ditch before the counter-guards is 10 toiſes broad. The ravelin not only covers the ſhoulders and the oillons of each baſtion, but likewiſe defends the ditch of the counter-guard, as he takes as much of its face as is ſufficient for ſeeing or diſcovering all that to make two batteries in, *viz.* a low one and a high one in the ſame manner as he does in the faces of the baſtions. He allows no more terre-plain in the ravelin, than what is juſt enough for the recoiling of his guns, leaving all the reſt of its inſide empty for the purpoſe of being able eaſily to countermine the rampart, and to prevent the enemy from making a lodgment in it, after he may have forced it.

The better to cover the batteries in the face of each baſtion, which defend the ditch of the ravelin, he adds in the angles of the counterſcarp of the ravelin *lunettes,* in the form of lozenges, allowing 20 toiſes for the ſemi-gorge in each. Theſe have their faces parallel to the counterſcarps of the ditches before the ravelin and counter-guard, and the ditch before them 8 toiſes broad.

The author likewiſe makes a *lunette* in his great ditch from 7 to 8 toiſes broad, which he carries quite round the work to prevent the low flanks, which would be otherwiſe eaſily acceſſible, from being got at. A ſmaller or narrower *lunette* might alſo be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or ravelins.

The calculations for the angles and lines of a conſtruction on the ſides of a polygon, according to Mr. Blondel's method, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the centre is equal to 60 degrees, the angle of the polygon to 120, and the angle *diminué*, B A F or A B E, to 25 degrees. The flanking-angle, A G B, is 130 degrees, and the flanked angle, N A G, or D B S, is equal to 70 degrees. Wherefore half the flanked angle, E B O, or F A P, is equal to 35 degrees.

The tenaille A G, and of courſe the face A C of the baſtion, is found by the following analogy.

As the ſine of the angle A G B
Is to the ſine of the angle A B G,
So is the exterior ſide A B
To the tenaille A G, of which the face A C is one-half.

From the line of defence A F, which is ſeven-tenths of the exterior ſide A B, we get the complement G F or G E, and the curtain E F of courſe by this analogy.

As the ſine of the angle E F G
Is to the ſine of the angle E G F,
So is the complement E G
To the curtain E F.

And as the ſum of the angles C E F, E C F, is equal to 180°—the angle *diminué* C F E (25°) = 155°, and C F, E F, are known, we have this analogy.

As the ſum of the ſides C F, E F
Is to their difference,
So is the tangent of 77° 30′, half the ſum of the angles,
To the tangent of half their difference.

Half this difference added to half the ſum, gives C E F the angle of the flank, and taken from half the ſum gives E C F the ſupplement of A C E the angle of the *epaule* or ſhoulder.

And for the flank C E we have the following analogy.

As the ſine of C E F, the angle of the flank,
Is to the ſine of the angle *diminué* C F E,
So is C F
To the flank C E.

The demi-gorge E P is determined by firſt finding the lengthened curtain F P by this analogy.

As the ſine of the angle A P F, which is known,
Is to the ſine of the angle F A P which is alſo known,
So is the line of defence A F = $\frac{7}{10}$ of A B
To the lengthened curtain F P.

Then from F P ſo found take the curtain E F, and there will remain the demi-gorge E P.

TABLE of the Angles of the different Parts of the Conſtruction, according to Mr. BLONDEL's Method.

Angles	A M B of the Centre.	Q A B of the Polygon.	M A B half of the of the Polygon.	N A C flanked, or of the baſtion.	M A C half of the flanked.	C A I diminué.	A G B flanking, or of the tenaille. tant from the counterſcarp, which diſtance therefrom forms its ditch. The principal object in erecting this counter-guard is to conceal from the enemies' view the low flanks oppoſite to it, whilſt its narrowneſs or ſmall breadth puts it out of his power to place his guns in after he has taken it.

The ſaliant angle of his ravelin is determined by the interſection of two arcs, deſcribed from the ſhoulders of the two adjoining baſtions, with a radius equal to the diſtance between them. Its faces produced meet thoſe of the baſtions about 6 toiſes from the ſhoulders and are bounded on the lines or faces of the counter-guards produced, which alſo determine the gorge of the ravelin.

The ditch of the ravelin is from 10 to 12 toiſes broad, and that it may be the better defended, Mr. Blondel takes, in the face of the baſtion, a ſpace equal to this breadth, commencing ſix toiſes from the ſhoulder, in which he makes a low battery of 4 or 5 feet high, and another on the inſide of the ſame height with the parapet of the place, and retired about 7 toiſes within the face.

The ditch before the counter-guards is 10 toiſes broad. The ravelin not only covers the ſhoulders and the orillons of each baſtion, but likewiſe defends the ditch of the counter-guard, as he takes as much of its face as is ſufficient for ſeeing or diſcovering all that to make two batteries in, *viz.* a low one and a high one in the ſame manner as he does in the faces of the baſtions. He allows no more terre-plain in the ravelin, than what is juſt enough for the recoiling of his guns, leaving all the reſt of its inſide empty for the purpoſe of being able eaſily to countermine the rampart, and to prevent the enemy from making a lodgment in it, after he may have forced it.

The better to cover the batteries in the face of each baſtion, which defend the ditch of the ravelin, he adds in the angles of the counterſcarp of the ravelin *lunettes,* in the form of lozenges, allowing 20 toiſes for the ſemi-gorge in each. Theſe have their faces parallel to the counterſcarps of the ditches before the ravelin and counter-guard, and the ditch before them 8 toiſes broad.

The author likewiſe makes a *lunette* in his great ditch from 7 to 8 toiſes broad, which he carries quite round the work to prevent the low flanks, which would be otherwiſe eaſily acceſſible, from being got at. A ſmaller or narrower *lunette* might alſo be made in the ditches of the outworks, particularly when there are batteries in the demi-lunes or ravelins.

The calculations for the angles and lines of a conſtruction on the ſides of a polygon, according to Mr. Blondel's method, are made in the following manner.

Since the figure referred to is a hexagon, the angle of the centre is equal to 60 degrees, the angle of the polygon to 120, and the angle *diminué*, B A F or A B E, to 25 degrees. The flanking-angle, A G B, is 130 degrees, and the flanked angle, N A G, or D B S, is equal to 70 degrees. Wherefore half the flanked angle, E B O, or F A P, is equal to 35 degrees.

The tenaille A G, and of courſe the face A C of the baſtion, is found by the following analogy.

As the ſine of the angle A G B
Is to the ſine of the angle A B G,
So is the exterior ſide A B
To the tenaille A G, of which the face A C is one-half.

From the line of defence A F, which is ſeven-tenths of the exterior ſide A B, we get the complement G F or G E, and the curtain E F of courſe by this analogy.

As the ſine of the angle E F G
Is to the ſine of the angle E G F,
So is the complement E G
To the curtain E F.

And as the ſum of the angles C E F, E C F, is equal to 180°—the angle *diminué* C F E (25°) = 155°, and C F, E F, are known, we have this analogy.

As the ſum of the ſides C F, E F
Is to their difference,
So is the tangent of 77° 30′, half the ſum of the angles,
To the tangent of half their difference.

Half this difference added to half the ſum, gives C E F the angle of the flank, and taken from half the ſum gives E C F the ſupplement of A C E the angle of the *epaule* or ſhoulder.

And for the flank C E we have the following analogy.

As the ſine of C E F, the angle of the flank,
Is to the ſine of the angle *diminué* C F E,
So is C F
To the flank C E.

The demi-gorge E P is determined by firſt finding the lengthened curtain F P by this analogy.

As the ſine of the angle A P F, which is known,
Is to the ſine of the angle F A P which is alſo known,
So is the line of defence A F = $\frac{7}{10}$ of A B
To the lengthened curtain F P.

Then from F P ſo found take the curtain E F, and there will remain the demi-gorge E P.

TABLE of the Angles of the different Parts of the Conſtruction, according to Mr. BLONDEL's Method.

This ingenious author alſo gives a table of the lengths of the different lines in his conſtruction on the two following ſuppoſitions:

1ſt. That the exterior ſide of each figure is equal to 200 toiſes.

And 2dly. That the exterior ſide of each figure is equal to 170 toiſes.

Mr. Blondel was undoubtedly a man of conſiderable talents and eminence, and had travelled over the greateſt part of Europe, America, and the Weſt Indies, making ſenſible and judicious obſervations on the various modes of fortifying, practiſed by different nations.

His acuteneſs however in diſcovering the miſtakes committed by others, and his anxiety to avoid them, did not prevent him from falling into ſtill greater ones himſelf. He did not attend ſufficiently to the great expence that the execution of his method would unavoidably occaſion, or to the numerous artillery that would be required for its defence.

Imagining, that places are generally loſt for want of ſufficient flanks, he makes three, one behind another. They are however ſo near to each other, that the rubbiſh of the higher ones muſt certainly render the lower ones uſeleſs: and were ſhells to fall into the lower ones they muſt unqueſtionably deſtroy the troops for want of room to avoid them. They are moreover too open and liable to be deſtroyed from the covert-way, as the counter-guards are not broad enough to cover and ſcreen them from the enemies' fire. The low flanks are too narrow and too much confuſed. Before ſhells, however, were much uſed at ſieges, they might have afforded a good defence.

He makes no uſe of traverſes. But this is not to be imputed to him as a fault or omiſſion, as rocket-firing was not uſed in his time.

His great ditch appears to be too wide, being not leſs than 25 toiſes before the faces of the baſtions.

His angle *diminué* muſt be allowed to be prepoſterouſly great, as he makes it of as many degrees as it ought to be in a conſtruction on a ſtraight line, or on the ſides of a polygon of an infinite or indefinite number of ſides.

The following is the conſtruction according to Mr. Bombelle's method.

Like Count Pagan he eſtabliſhes three ſorts of fortification. But inſtead of conſtructing inwards like him, he conſtructs outwards. His three ſorts he denominates the little royal, the mean, and the great royal. The interior ſide of the little royal is equal to 60 rods of 12 Paris feet each, or 120 toiſes, that of the mean is equal to 70 ſuch rods or 140 toiſes, and that of the great royal is equal to 80 ſuch rods or 160 toiſes. His manner of fortifying in all the three is the ſame, and is the following.

Having determined on the ſide A B, (*fig.* 4.) (which we ſhall here ſuppoſe to be that of a hexagon), for the great, mean, or little royal, allow a fifth part of it for the demi-gorges A C, B D; and a fourth part of it for the flanks C E, D F, each of which muſt make, with the curtain C D, an angle of 100 degrees. Then the points, G, H, of the baſtions are aſcertained by the raſant lines C H, D G, and the whole operation or conſtruction is furniſhed.

As the conſtruction in this figure is ſuppoſed to be made outwards on three of the ſides of a regular hexagon, the angle A O B of the centre is equal to 60 degrees, and the angle G H K of the polygon is equal to 120 degrees. But the angle E C D of the flank is by conſtruction equal to 100 degrees, the demi-gorge A C or B D is equal to a fifth part of the interior ſide A B, and the flank C E or D F is equal to a fourth part of A B. Conſequently the ſum of the angles C D E, C E D, is given equal to 80 degrees, and the ſides C E, C D, are given; wherefore we have this analogy.

As the ſum of the curtain C D and flank C E
Is to their difference,
So is the tangent of 40° half the ſum of the angles C D E, C E D
To the tangent of half their difference.

Hence the angle *diminué* C D E or C D G, the angle C E D the ſupplement of the angle C E G of the *epaule* or ſhoulder, and A G D half the flanked angle, or half the angle of the baſtion, are given.

And as the lengthened curtain A D or B C is given by the conſtruction equal to four fifths of the interior ſide A B, we have the following analogies for D G, the line of defence, and A G the capital of the baſtion.

As the ſine of A G D, half the angle of the baſtion,
Is to the ſine of the angle G A D,
So is the lengthened curtain A D
To the line of defence D G.

And,

As the ſine of A G D, half the angle of the baſtion,
Is to the ſine of the angle *diminué* A D G
So is the lengthened curtain A D
To A G the capital of the baſtion.

In like manner we obtain D E from the triangle C E D by means of the following analogy.

As the ſine of C D E, the angle *diminué*,
Is to the ſine of E C D, the angle of the flank,
So is the flank C E which is given
To the right line D E, which taken from D G, the line of defence, gives E G the face of the baſtion.

And as in this figure, which is ſuppoſed to be a hexagon, the exterior ſide G H, or line joining the ſaliant angles of two adjoining baſtions, is equal to O G the perpendicular diſtance of the point I, the interſection of the lines of defence from G H is obtained by the following analogy.

As radius
Is to the tangent of I G Z, the angle *diminué*,
So is G Z, the half of G H or O G, in this figure,
To I Z, the perpendicular diſtance of I from G H.

And the perpendicular diſtance of the interſection of the raſant lines, or lines of defence, from the curtain, is found by this analogy.

As G H or O G in this figure
Is to the curtain C D,
So is I Z
To the perpendicular diſtance I Y of I from C D.

And in any other regular figure than a hexagon, G H is found by this analogy.

As O A, the radius of the circumſcribing circle,
Is to the interior ſide A B, which is given,
So is $OG = OA + AG$
To G H, the ſide of the exterior polygon.

And as radius
Is to the tangent of I G Z, the angle *diminué*,
So is G Z equal to half G H,
To I Z, the perpendicular diſtance of I from G H.

And as G H, the ſide of the exterior polygon,
Is to C D the curtain, which is known,
So is I Z, the perpendicular diſtance of I from G H,
To I Y, the perpendicular diſtance of I from the curtain.

Mr. Bombelle, in the conſtruction of each of his three ſorts of fortification, makes the angle E C D or F D C of the flank, always equal to 100 degrees, and the angle *diminué* G D C or H C D invariably equal to about 20° 56′.

For CD being always equal to three-fifths of AB, and CE equal to a fourth part of AB, the ratio of CD + CE to CD − CE is a given or conſtant ratio, being that of 17 to 7, whatever be the length of AB. And the conſtruction of his mean fortification gives the demi-gorge AC or BD, equal to 28 toiſes, the curtain CD, equal to 85, the lengthened curtain AD or BC, equal to 112, the flank CE or DF, equal to 35, the line of defence DG or CH, equal to about $153\frac{5}{8}$, the capital AG or BH of the baſtion, equal to about $63\frac{1}{2}$, the face GE or HF of the baſtion, equal to about $61\frac{1}{3}$. And in all the three the ratio of DY half the curtain, to IY the perpendicular diſtance from it to I, the interſection of the lines of defence, or of GZ, half the ſide of the exterior polygon, to ZI, the perpendicular diſtance from it to the ſaid point of interſection, is given or conſtant, being always that of radius to the tangent of 20° 56′. The conſtruction of his mean fortification on the ſides of a hexagon gives ZI, equal to about 38,884 toiſes, and YI to about 16,066 toiſes.

This author makes his main ditch, or the ditch of the body of the place, 12 rods of 12 Paris feet each, or 24 toiſes broad, beyond which and oppoſite to the curtain he places a ravelin, the ſaliant angle of which is in the interſection of two arcs deſcribed with the lengthened curtain AD, or BC, as radius from the extremities A, B, of the interior ſide AB, and the faces of which produced acroſs the main ditch would terminate on the ſhoulders *i*, *i*, of the ſquare orillons, that cover his rounded flanks or caſemates, which are deſcribed in the following manner.

From the extremities C, D, of the curtain, and perpendicularly thereto, he draws two other flanks, C*i*, D*i*, meeting the lines of defence in the points *i*, *i*, lengthening the faces GE, HF reſpectively by E*i*, F*i* in order to have room enough in each flank of every baſtion for two covered ones, which are conſtructed in the following manner:

Take the two lines G*r*, H*r*, equal each to a third part of G*i* or H*i*, (C*i*, D*i* being drawn from the extremities C, D, of the curtain CD perpendicular thereto), and the lines *ik*, *ik*, alſo equal each of them to a third part of C*i* or D*i*. From the points, *r*, *r*, draw right lines, *rkl*, *rkl*, through the points *k*, *k*, terminated at the points *l*, *l*, by the right lines C*l*, D*l*, drawn perpendicularly to the lines of defence GD, HC, which muſt be produced till they meet the radii of the polygon in ſome points as *p*, *p*, in order to take upon the ſame radii the diſtances *pq*, *pq*, for terminating the covered flanks, of which the common centre *x* is found by deſcribing from the extremities D*l*, C*l*, of the right lines C*l*, D*l*, arcs with a radius equal to three-fourths of C*l* or D*l*.

The diſtance between the two covered flanks on each flank of every baſtion is equal to 12 rods of 12 Paris feet each, or twenty-four toiſes, and the parapets every where are 10 ſuch rods or 4 toiſes thick.

The caſemates which Mr. Bombelle adds at the points of the baſtions, and which, in caſes of neceſſity, may ſerve as retrenchments, are deſcribed by taking on the capitals of the baſtions the right lines G*s*, H*s*, equal reſpectively to half the lines G*r*, H*r*, and deſcribing from the points *s*, *s*, as centres, arcs, *rr*, *rr*, for the caſemates, each of which has its parapet 4 toiſes broad. They are ſomewhat lower towards the points of the baſtions than the other parts of the baſtions, and the ways to them are through paſſages as *o*, *o*, in the baſtions.

This author covers his ravelin with a ſort of counterguard or tenaille beyond its ditch, which he makes 8 rods of 12 Paris feet each, or 16 toiſes broad, or a third part of the breadth of his great ditch, thus rendering his ravelin a tenailleid, or horned half-moon.

Round covered flanks were firſt invented by the Italians; and Mr. Bombelle uſes them in order to render them the more capacious, and the fitter for reſiſting the ſhock and effects of the enemies' cannon. They ſeem, however, to have too much convexity, advancing too far towards the centre of each baſtion, and leaving too ſmall a diſtance between the two high flanks.

As his flanks are great, he makes uſe of no ſecond flanks on the curtains. But contrary to ſound ſenſe and reaſon, and inconſiſtently with the genuine principles of conſtruction, he makes them of the ſame lengths or ſizes in all polygons. His angle *diminué* alſo is invariably of a given magnitude, *viz.* of 20° 56′, which by his conſtruction on the ſides of a ſquare leaves the flanked angle, or angle of each baſtion, equal only to 48° 8′ in a pentagon, to 66° 8′, in a hexagon, to 78° 8′, and ſo on. His angle *diminué* in a ſquare, is therefore more than double what it ought to be, by upwards of two degrees. And in a pentagon it does not fail quite $7\frac{1}{2}$ degrees ſhort of being twice as great as it ſhould be in reality. He makes it even greater in a ſquare than it ought to be in an octagon.

Mr. Vauban in his method fortifies inwards; and like Count Pagan, from whom he has borrowed his perpendicular for the hexagon and all higher polygons, begins with the perpendicular to the exterior ſide, and the raſant lines or lines of defence. He does not, however, make the faces of his baſtions ſo long, or his flanks quite ſo ſhort. And he omits ſecond flanks as not of very great moment, as they can be added at any time, without changing either the flanks or curtains.

Biſect, as in Count Pagan's conſtruction, the exterior ſide AB in the point C. (*fig.* 5.) At the point C erect a perpendicular, CD, equal to an eighth part of AB in the ſquare, to a ſeventh part of AB in the pentagon, and to a ſixth part of AB in the hexagon and all higher polygons. From the extremities A, B, through the point D, draw the lines of defence ADH, BDG. On theſe take AE, BF for the faces of the baſtions, equal each to two ſeventh parts of AB, and take EH, FG, each equal to EF, the diſtance between the ſhoulders E and F. Then join the points G, H, for the curtain GH. And if a ſimilar conſtruction be made on each of the other ſides of the figure or polygon, we get the maſter-line of the curtains and baſtions, or the principal or outline of the body of the place. To this muſt be added a rampart from 10 to 12 toiſes broad at the baſe, and elevated more or leſs above the level of the place, on the outer part of which, at top, there is raiſed a parapet three toiſes broad at the baſe, and elevated above the rampart from ſix feet to $7\frac{1}{2}$. The ditch of the body of the place, or the great ditch, is 20 toiſes wide oppoſite to the flanked angles or ſaliant angles of the baſtions, and it is formed by deſcribing from theſe angles with a radius of 20 toiſes, circular arcs, and drawing right lines from the *epaules*, or ſhoulders, to touch theſe arcs. For the parts of theſe lines lying between their interſections and the points of contact, together with theſe arcs, form the outline of the ditch.

The foregoing figure is a regular hexagon, and the exterior ſide is here ſuppoſed to be equal to 180 toiſes.

To determine the ſaliant angle S (*fig.* 6.) of the half-moon or ravelin, ſet off 50 toiſes on the perpendicular DC, produced beyond the exterior ſide AB; from the point S draw right lines to the counterſcarp of the great ditch, ſo that if produced acroſs the ſame, they would, according to ſome authors, terminate on the *epaules* or ſhoulders of the baſtions, but according to others, about 3 toiſes from the ſhoulders on the faces of the baſtions. Theſe lines ſo drawn from the ſaliant angle S, of the ravelin to the counterſcarp, form the faces SL, SM, of the half-moon or ravelin. It is generally ſuppoſed that when the faces SL, SM of the ravelin terminate when produced acroſs the great ditch on the faces of the baſtions a few toiſes from the *epaules* or ſhoulders, they cover the flanks much better than they do when they terminate on the ſhoulders themſelves.

The ditch before each ravelin is 12 toiſes broad; its counterſcarp is parallel to the faces, and is made of a circular form, before the ſaliant angle of each like the ditches before the ſaliant angles of all works in general.

When the ravelin is made with flanks, as PN, QO, the faces SP, SQ, when produced acroſs the great ditch, ought to terminate on the faces of the baſtions 5 toiſes at leaſt from the *epaules* or ſhoulders.

When a ravelin has flanks, they are commonly made by ſetting off 10 toiſes from L to P, and M to Q, from the extremities of the faces, and by drawing them from the points P, Q, parallel to the capital *r*S of the ravelin.

There is ſometimes a redoubt made in a ravelin, which is done by ſetting off from the extremities, L, M, of the faces on the ſemi-gorges L*r*, M*r*, and then drawing right lines for its faces parallel to thoſe of the ravelin. The ditch before ſuch a redoubt ſhould be 6 toiſes broad, and its counterſcarp parallel to its faces.

Orillons and retired flanks are deſcribed in the following manner.

The front, AEG, HFB, being deſcribed as above taken, E*a* equal to a third part of the flank EG. From the oppoſite flanked angle B, draw the right line B*a*, on which produced take *ab*, equal to 5 toiſes. Take alſo on the line of defence, BG, produced, G*e* equal to 5 toiſes, and join *b*, *c*. On *be* as a baſe deſcribe the equilateral triangle *bcf*, and from the angular point *f* as a centre, deſcribe the circular retired flank *be* with the radius *fb* or *fe*.

Again, if E*a* be biſected in the point *c*, and *cd* be drawn perpendicularly to E*a* to meet a perpendicular to the face AE, from the point E in the point *d*, and if from the point *d* as a centre a circular arc be deſcribed with *d*E as radius, we ſhall get the circular orillon E*a*.

ab is called the revers, or back part of the orillon, and G*e*, the *enfoncement* or depth of the caſemate or concave flank *bc*.

In like manner are the retired or concave flank *hi*, and the circular orillon F*g* deſcribed.

The orillons are uſeful in covering the retired or concave flanks, which by means of them cannot be ſeen but directly in front. And as Mr. Vauban makes his orillons round, they cannot be ſo eaſily deſtroyed as they might be were they of any other figure or form.

The calculation of the lines and angles of a conſtruction on a polygon, according to this method of Mr. Vauban, is as follows:

If AB be ſuppoſed to be the ſide of a hexagon, the angle of the centre will be equal to 60°, and the angle of the polygon to 120°. And as the perpendicular CD is by the conſtruction equal to a ſixth part of AB, the angle *diminué* ABD or BGH is determined by the following analogy:

As AC or BC, the half of AB, } or, As 3
Is to CD the perpendicular, } Is to 1,
So is radius
To the tangent of the angle CAD or CBD, which is nearly equal to 18° 26′ 6″. Wherefore the flanked angle or angle of the baſtion is equal to 83° 7′ 48″ nearly. And ſince the triangle EFG is iſoſceles by the conſtruction, and the angle EFG, which is equal to the angle ABD, is of courſe equal to 18° 26′ 6″, we have the angles FEG, FGE, equal each to half the exceſs of 180° above 18° 26′ 6″, or to 80° 46′ 57″ nearly. Wherefore the angle EGH of the flank, which is equal to the angle FGE, together with the angle FGH, or angle *diminué*, is equal to 99° 13′ 3″. And the angle AEG of the *epaule*, or ſhoulder, being equal to the angle EGF or EGD, together with the angle EDG, which is equal to the angles ABD, BAD, taken together, or to twice the angle *diminué*, is equal to 117° 39′ 9″.

Now ſince AC, half of the exterior ſide AB, is given, and CD is found by the foregoing analogy, AD is known, its ſquare being (47 E. 1.) equal to the ſquares of AC and CD; and as AE is equal to two-ſevenths of AB, the exterior ſide ED is known. But AD is to ED, as AB is to EF or FG, which are of courſe known. Or, either of theſe lines may be found by the following analogy.

As the ſine of the angle EFD, which is equal to the angle *diminué*, or to 18° 26′ 6″,
Is to its oppoſite ſide DE,
So is the ſine of the angle EDF, which is equal to 180°, twice the angle *diminué*, or to 143° 7′ 48″,
To the oppoſite ſide EF, the diſtance between the epaules.

And if from EF, or its equal EH, there be taken ED, the complement DH, or its equal DG, will be known. Wherefore the curtain GH is determined by either of the two following analogies.

As AD
Is to the exterior ſide AB,
So is the complement DG or DH
To the curtain GH.
Or, As the ſine of the angle *diminué* DGH
Is to the ſine of the angle GDH, which is = 143° 7′ 48″ nearly,
So is the complement DH
To the curtain GH.

The flank EG is eaſily found by means of either the triangle EFG, or the triangle EDG, as in the following analogies.

As the ſine of the angle FGH, which is = 80° 46′ 57″ nearly,
Is to the ſine of the angle EFG, which is = angle *diminué*, or 18° 26′ 6″ nearly,
So is EF the diſtance between the two oppoſite epaules
To the flank EG.
Or, As the ſine of the angle EGD, which is = 80° 46′ 57″ nearly,
Is to the ſine of the angle EDG, which is = twice the angle *diminué*, or 36° 52′ 12″ nearly,
So is ED the diſtance from the epaule to the interſection of the lines of defence
To the flank EG.

And as half the flanked angle is equal to 41° 33′ 36″, and the angle AHG, which is equal to the angle *diminué*, to 18° 26′ 6″ nearly; the angle formed by the capital of the baſtion, and the lengthened curtain, or the curtain HG produced to meet the ſame, will be equal to 120° 0′ 18″ nearly. Wherefore the lengthened curtain is found by this analogy.

As the ſine of 120° 0′ 18″
Is to the ſine of 41° 33′ 36″, half the flanked angle,
So is AH
To the lengthened curtain: from which, if the curtain HG be taken, we get the demi-gorge.

And the capital of the baſtion is found by this analogy:

As the ſine of 120° 0′ 18″

Is to the ſine of 18° 26′ 6″, the angle *diminué*,
So is AH
To the capital of the baſtion.

And the perpendicular diſtance, DI, of the curtain from the interſection of the lines of defence is found by the analogy, As AB is to CD, ſo is GH to DI.

Suppoſing the exterior ſide AB, as in his mean fortification, to be equal to 180 toiſes, the principal lines belonging to the conſtruction may eaſily be found, as in the following manner.

The perpendicular CD being by conſtruction $= \frac{AB}{6}$ is $=$ 30 toiſes.

The *tenaille* AD or BD being equal to $\sqrt{BC^2 + CD^2}$ is equal to $\sqrt{9000}$ toiſes $= 30\sqrt{10} = 94.8683298$ nearly.

The face BF of the baſtion is commonly equal to 50 toiſes, or two-ſevenths of AB nearly.

The diſtance DF of the *epaule* F from the interſection D of the lines of defence being equal to $BD - BF$, is equal to $10\sqrt{90} - 50 = 44.8683298$ toiſes nearly.

If from the *epaule* F there be drawn Fl perpendicular to the exterior ſide AB, we ſhall have $Bl = \frac{BC \times BF}{BD} = 5\sqrt{90}$ toiſes $= \frac{BD}{2} = 47.4341649$ toiſes nearly; and Fl the perpendicular diſtance of the *epaule* F from the exterior ſide $= \frac{CD \times BF}{BD} = 5\sqrt{10}$ toiſes $= \frac{BD}{6} = 15.8113883$ toiſes nearly.

The diſtance EF, between the two oppoſite *epaules*, E, F, or its equal EH or FG, is equal to $AB - 2\,Bl = AB - BD = \overline{180 - 30\sqrt{10}}$ toiſes $= 85.13167$ toiſes nearly.

The complement DG or DH being equal to $FG - DF$ is equal to $\overline{230 - 10\sqrt{360}}$ toiſes $= 40.26334$ toiſes nearly. The perpendicular diſtance DI of the interſection of the lines of defence from the curtain GH being $= \frac{CD \times DG}{BD}$ is equal to $\overline{23\sqrt{10} - 60}$ toiſes, or 12.7323861846 toiſes nearly. Conſequently the perpendicular diſtance CI between the exterior ſide AB and the curtain GH being equal to $CD + DI$, is equal to 42.7323861846 toiſes nearly.

The curtain GH being equal to ſix times DI, is equal to $\overline{138\sqrt{10} - 360}$ toiſes, or 76.3943171 toiſes nearly.

If Fm be drawn perpendicularly from the *epaule* F to AH, the line of defence, Em, being equal to $\frac{EF \times BC}{BD}$ is equal to $\overline{54\sqrt{10} - 90}$ toiſes, or 80.76299365 toiſes nearly.

The perpendicular Fm being to Em as CD is to BC, is equal to a third part of Em or $\overline{18\sqrt{10} - 30}$ toiſes, or 26.921 toiſes nearly.

The diſtance mH of the point m from the extremity H of the line of defence being equal to $EH - Em$, is equal to $\overline{270 - 84\sqrt{10}}$ toiſes, or 4.3686765442 toiſes nearly.

The diſtance Dm of the point m from the interſection D of the lines of defence being equal to $Em - DF$ or $Em - DE$, is equal to $\overline{24\sqrt{10} - 40}$ toiſes, or 35.8946538448 toiſes nearly. But ſince FEH is an iſoſceles triangle, the angle FEH or DBC is equal to twice the angle mFH, which is therefore equal to 9° 13′ 3″ nearly.

The flank FH being equal to $\sqrt{Fm^2 + mH^2} = 3\sqrt{16400 - 5100\sqrt{10}}$ toiſes, is equal to 27.27322895 or 27.273 toiſes nearly. And if from the extremity H of the line of defence AH there be drawn Hn to meet the face FB of the baſtion in the point n, we ſhall have Hn equal to $\frac{DH \times Fm}{Dm} = \frac{\overline{230 - 60\sqrt{10}} \times \overline{18\sqrt{10} - 30}}{24\sqrt{10} - 40}$ toiſes, or 30.1976 toiſes, exceeding the perpendicular CD to the exterior ſide by 0.1976 of a toiſe only.

And as Fn is a fourth proportional to Dm, mH, and DF, or is equal to $\frac{mH \times DF}{Dm} = \frac{\overline{270 - 84\sqrt{10}} \times \overline{30\sqrt{10} - 50}}{24\sqrt{10} - 40}$ toiſes, it is equal to 5.461 toiſes nearly. And Dn is equal to 50.3292 toiſes nearly.

Now in Count Pagan's conſtruction, from whom Mr. Vauban has borrowed the length of his perpendicular, on which the other parts chiefly depend, the flank FH is equal to $\overline{18\sqrt{10} - 33}$ toiſes, or to 23.921 toiſes nearly, which falls ſhort of the perpendicular Fm, drawn from the *epaule* F, in Vauban's conſtruction, to the line of defence AH, by 3 toiſes, and of the flank FH by 3.35222895 toiſes. In any polygon, having its exterior ſide equal to 180 toiſes, their perpendiculars are equal, as well as the ſaliant angles of their baſtions. And we are perſuaded, that even the greateſt admirers of Vauban can aſſign no good reaſon for his not having followed Count Pagan alſo, with regard to the poſition of his flank, and placed it at right angles to the line of defence, inſtead of making them meet in an angle of 80° 46′ 57″. There is great reaſon to ſuppoſe, that the Count would have made the face of his baſtion conſiderably ſhorter than he did, had he not intended to have three flanks inſtead of one. He makes it 55 toiſes. But it is naturally to be preſumed, that, had he intended to conſtruct with a ſingle flank, he would have biſected the perpendicular diſtance between his orillon and inner flank, (which is 19 toiſes,) and drawn his flank at right angles to the line of defence through this point of biſection, thereby forming a more complete conſtruction for the body of the place than Vauban has done. And it is ſomewhat remarkable, that this line nearly coincides with the perpendicular Hn, to Vauban's line of defence, from its point H of interſection with the flank. Had he therefore, inſtead of taking 5 toiſes from the face of Count Pagan's baſtion, taken 10, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his baſtion its proper length, and, at the ſame time, made the flank itſelf about equal to the perpendicular, as it ought to be, ſince perpendiculars to the exterior ſides of polygons were firſt introduced into conſtruction for the ſole purpoſe of obtaining flanking defences. The lengths, however, with both theſe authors, as well as the other writers on fortification, are merely arbitrary, and by no means derived from reaſoning either on the properties of the figures, or their relative degrees of importance and capability of defence. For there appears no reaſon for giving the ſame perpendicular to a hexagon and every other polygon of a greater number of ſides, as Vauban has done, or to all regular figures above the ſquare, as Count Pagan has done.

This author retains part of the fauſſe-bray, which uſed to go round the whole body of the place, at the diſtance of from 4 to 5 toiſes from the ſame, making uſe of it as *tenailles* oppoſite to his curtains, which are made differently.

A tenaille is commonly from two to three feet only higher than the level ground of the ravelin. The tenaille *abcdefg*, (*Plate* VI. *fig.* 7.) is conſtructed by firſt ſetting off from the epaules E, F, on the lines of defence E*a*, F*g*, equal each to three toiſes, for a paſſage between it and the flanks of the baſtions; then taking *ab*, *gf*, for its faces, equal each of them to 16 toiſes, by deſcribing from the ſhoulders *b* and *f*, as centres arcs with a radius equal to *bf*, and then by interſecting theſe arcs from the ſame ſhoulders as centres, with a radius equal to 10 toiſes, for its flanks *bc*, *fe*. Some, however, make the faces *ab*, *gf*, equal to half the lines *a*D, *g*D reſpectively, and place the flanks at right angles to the lines of defence, which is certainly the beſt poſition for them.

The tenailles *abcd*, *efgh*, (*fig.* 8.) are without flanks, and have their faces on the lines of defence. The paſſage between them, as well as the paſſages between them and the flanks, are three toiſes wide. Theſe are called *ſimple tenailles*, and the foregoing is called a *reinforced tenaille*. There is alſo a third ſort of tenailles, which have only faces *ab*, *gf*, and flanks *bc*, *fe*, without a curtain *ee*.

Simple tenailles, with their faces on the lines of defence, but without flanks, are not ſo well calculated for ſcouring and defending the ditch as either the *reinforced tenailles* are, or thoſe with faces, and flanks without curtains. However, as they are not liable to be enfiladed, Mr. Vauban has generally preferred them to the other two, in moſt of the places which he fortified.

The *reinforced tenailles* defend the ditch much better, and add low flanks to thoſe of the baſtions, but are liable to have their own flanks enfiladed, an inconvenience that might be remedied by conſtructing them in ſuch a manner as to be covered by the extremities of the parapets of the oppoſite ravelins, or by the adjoining *lunettes*. Theſe are well calculated for ſcouring not only the ditch, but alſo the level ground of the ravelin, and the ditch before the *corps de guard*, *reduit*, or redoubt, commonly made within it, which cannot be ſo well ſeen or defended from any other parts.

Thoſe with faces and flanks only, have the ſame advantages with theſe as to the defending or ſcouring of the ditch, but are alſo, like them, liable to have their flanks enfiladed, which ſhould be guarded againſt in the ſame manner.

The better to ſcour and defend the ditch, and oppoſe its paſſage, this fortifier places in it, oppoſite to the middle of the *tenaille*, or of the curtain, a caponiere, or double way, covered with a parapet raiſed three feet above the bottom of the ditch. It is about 12 feet broad, is perpendicular to the curtain, and is paliſaded on both ſides. This work is good, and very uſeful, as it commands without being commanded, and ſerves as a paſſage for the muſketeers from the body of the place to the outworks. He thus has four flanks for the defence of his ditch, namely, that of the body of the place, that of the orillon, that of the tenaille, and the caponiere.

Tenailles are reckoned ſo neceſſary, that it is with good reaſon that there are few places fortified without them. For when the ditch is dry, the ſpaces behind them ſerve as places of arms, from which the troops may ſally to oppoſe the enemies' deſcent of the ditch, to retard his operation, and deſtroy his works in it, and then retire to them as places of ſafety. They alſo render the communication between the body of the place and the ravelins more eaſy and ſecure, which is a great advantage, as the ravelins are thereby enabled to make a much better defence than they otherwiſe could do, being readily ſupplied at any time with troops and neceſſaries. And when the ditch is wet, the ſpaces behind them ſerve as harbours for boats, which armed men can make uſe of, both for oppoſing the paſſage of the ditch, and for facilitating the communication between the tenailles and the ravelins.

This fortifier, in order to increaſe the ſtrength of a place, places frequently works called *lunettes* (which literally ſignify ſpectacles) on both ſides of his ravelin. He ſometimes makes one face of his lunette perpendicular to the middle of the face of the ravelin, and ſometimes perpendicular to the face of the ravelin, and ſo as produced to the ſame about one-third from the ſaliant angle. In the former caſe he makes that face of the lunette equal to 30 toiſes, and determines its other faces by taking for the demi-gorge 25 toiſes, on the counterſcarp of the great ditch from that of the ditch before the ravelin; and in the latter he makes the demi-gorge equal to 20 toiſes only. The ditch before the lunettes is 12 toiſes broad, the thickneſs of the parapet is equal to three toiſes, and that of the rampart to eight, as in the ravelin.

When he makes uſe of lunettes, he ſometimes covers the ſaliant angle of the ravelin with a work called *bonnet*, of which the faces are parallel to thoſe of the ravelin, and when produced biſect thoſe of the lunettes. The ditch before it is ten toiſes wide.

Tenaillons. The term *tenaillon* is ſometimes applied to a reinforced tenaille; but it is generally confined to a work ſomewhat like a lunette, made on each ſide of a ravelin, but differing from a lunette in this circumſtance, that one of the faces of a tenaillon, though it is 30 toiſes long, like that of the lunette, is in the direction of the ravelin produced beyond its ditch, whereas that of the lunette is perpendicular to it. The other face of the tenaillon is determined by taking 15 toiſes on the counterſcarp of the great ditch from that of the ravelin. There is ſometimes in a tenaillon a battery 15 toiſes long, and 10 toiſes retired from the front and parallel thereto.

There are generally retrenchments in tenaillons which have their parapets either parallel to their fronts or perpendicular to their other faces, which, when produced, terminate on the faces of the baſtions. The ditch before ſuch a retrenchment is about three toiſes wide; and as theſe works are commonly made of earth, without any revetement of maſonry, there is a banquette, called *berm*, before the parapet, next to the ditch, about eight feet broad, to prevent it from falling into the ſame.

As to the conſtruction of counter-guards, horn-works, crown-works, covert-ways and glaces, detached redoubts, ſecond ditches, and covert-ways, and profiles. See the ſame under theſe articles reſpectively.

Mr. Vauban, in his ſecond method with tower-baſtions, according to the plans of Landau and Beſford, begins with his conſtruction inwards, and fortifies outwards in the following manner.

Suppoſing A B (*fig.* 9.), to be the interior ſide of the hexagon of 120 or 130 toiſes, draw A C, B D from the centre thereof, through the extremities A, B; ſet off ſix toiſes from A to *b*, and from B to *c*; through the points *b* and *c*, draw right lines at right angles to A B, on which ſet off ſix toiſes from *b* to *f*, and *c* to *h*, and four toiſes from *b* to *d*, and *c* to *g*; and from the points *f*, *d*, draw perpendiculars *fr*, *dn*, to the capital A C, as alſo from the points *h*, *g*, perpendiculars to the capital B D. Then, if *r* E be taken equal to *rf*, and *p* F to *ph*, the points E, F, will be the ſaliant angles of the tower-baſtions, of which E*fdn* and F*hgq* are the halves.

If on the capitals A C, B D, there be taken E C, F D, equal each to 40 toiſes, the points C, D, will be the ſaliant angles of the counter-guards before the towers. From the points C, D, draw the lines of defence C*c*, D*b*, to the points *c*, *b*, where the flanks of the towers interſect the curtain. On theſe ſet off 56 toiſes, from C to G, and D to H, for the faces C G, D H, of the counter-guards. The flanks and tenailles are found or determined as in his firſt method.

The ditch before the ſaliant angles of the towers is ſix toiſes broad, and its counterſcarp is drawn to the extremities of the flanks of the counter-guards. The right line, which joins the ends of theſe flanks, determines the inſide of the tenailles.

The ditch before the counter-guards is 12 toiſes broad at the ſaliant angles, and its counterſcarp is drawn towards the oppoſite ſhoulders, in the ſame manner as in his firſt method.

The capital of the ravelin is 45 toiſes, and its faces, when produced, terminate on thoſe of the counter-guards, about 10 toiſes from the ſhoulders. Ten toiſes, however, are cut off from the faces of the ravelin, for the flanks which are parallel to its capital.

The ditch before the ravelin is 10 toiſes broad, the covert-way five, the ſemi-gorges of the places of arms 12 each, the faces 17 each, and the glacis is 20 toiſes broad.

The conſtruction of Mr. Vauban's third method, according to the plan of New Briſach, is applied to an octagon, of which the exterior ſide is equal to 180 toiſes, and is made inwards. The perpendicular to the exterior ſide is, as in his firſt method, equal to 30 toiſes. The faces of the counter-guards are each of them equal to 60 toiſes. The flanks are found by ſetting off 22 toiſes, in arcs deſcribed from the oppoſite ſhoulders, as centres, and with the diſtance between as radius. A right line drawn through the extremities of the flanks, parallel to the exterior ſide, to meet the capitals of the counter-guards, determines both the inſide of the tenailles, and the ſaliant angles of the tower-baſtion.

And if another right line be drawn parallel to this, at the diſtance of nine toiſes from it, the points, where it meets or interſects the capitals of the counter-guards, will be centres of the towers; from which points, if ſeven toiſes be ſet off each way for their demi-gorges, the poſitions of their flanks, which are perpendicular to the ſaid line, will be determined. For each of theſe flanks, five toiſes are ſet off outwards, and four from the ſaid line. And the line joining the inſide of the flanks at the end of four toiſes completes the towers.

The ditch is ſix toiſes broad before the ſaliant angles of the towers, and its counterſcarp meets the line joining theſe angles, within ten toiſes of the extremities of the flanks of the counter-guards.

The great ditch before the counter-guards is 15 toiſes broad, and its counterſcarp is parallel to the faces. The capital of the ravelin is 55 toiſes in length, and that of the redoubt within it, is equal to 23 toiſes. The faces of the ravelin are drawn towards thoſe of the counter-guards, within 15 toiſes from the ſhoulders, and thoſe of the redoubt are parallel to theſe. Twelve toiſes are cut off from each face of the ravelin, and ſix from each of the redoubts by the flanks, which are parallel to its capital. The ditch before the ravelin is twelve toiſes wide, and that before the redoubt is ſix. The covert-way and glacis are the ſame as in his ſecond method. The profiles alſo are nearly the ſame in both. This method, indeed, differs but little from his ſecond, except in two ſmall flanks, of about four toiſes each, which in this he makes in each curtain, that are not in the other. The parapets of his counter-guards, on both ſides of the ſaliant angles for the diſtance of about twenty feet, are raiſed four feet higher than the reſt, to prevent theſe works from being annoyed by ricochet-batteries.

In Mr. Vauban's firſt method of military conſtruction, it may not be amiſs to give a table of the principal parts thereof, for drawing the maſter-line by, as alſo an ichnographical one of the principal dimenſions of the body of the place, tenailles, ravelin, covert-way, traverſes, and places of arms, as publiſhed with his approbation (for he never publiſhed any thing himſelf reſpecting it.)

TABLE for the Conſtruction.

	Forts.						Little Fortification.				Mean.		Great.	
Side of Figure, or Polygon.	80	90	100	110	120	130	140	150	160	170	180	190	200	260
Perpendiculars.	10	11	12½	14	15	16	20	21	23	25	30	31	25	22
Faces of Baſtions.	22	25	28	30	33	35	40	42	45	47	50	53	55	60
Capitals of Ravelins.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

And the following is an ichnographical table of the thickneſſes, &c. of the works compoſing the body of the place, &c.

		Toiſes.
Of the Body of the Place.	Thickneſs of the rampart at its baſe	11
	Thickneſs of the parapet at its baſe	3
	The breadth of the ditch	20

		Toiſes.
Of the Tenaille.	Its diſtance from the orillon of the baſtion	3
	Thickneſs of its rampart in the face and flank at the baſe	7
	Thickneſs of the rampart of its curtain at the baſe	5
	Thickneſs of its parapet at the baſe	3

Thickneſs

		Toiſes.
Of the Half-moon or Ravelin.	Thickneſs of its rampart at the baſe	10
	Thickneſs of its parapet at the baſe	3
	The breadth of its ditch	12
Of the Covert-way, Traverſes, and places of Arms.	The breadth of the covert-way	5
	Length of the demi-gorge of the places of arms at the re-entering angles	10
	Length of the faces, each of the places of arms	12
	Length of the traverſes at the re-entering angles	5
	Length of the traverſes at the ſaliant angles	$4\frac{1}{4}$
	Thickneſs of each traverſe at the baſe	3

The traverſes on the ſides where their banquettes are, or on their inſides, are from 5 to $5\frac{1}{2}$ feet high, and from 3 to 4 on the outſide, towards the covert-way, which they ſcour at the re-entering angles.

He gives his caponiere a banquette on each ſide, and the parapet of the place two or three, to ſuit men of different heights or ſtature, that they may all of them fire on the ſame level.

He makes a cut oppoſite to each traverſe in the parapet of the covert-way, $4\frac{1}{2}$ or 5 feet deep, for the ſoldiers to paſs, which he ſhuts up with a ſmall merlon, except at the ſaliant angles, where ſuch cuts could not be ſeen by thoſe who defend the place.

When he gives flanks to his ravelin, he makes places of arms in its ditch, perpendicular to its faces, and near the angles of the epaules, to prevent the paſſage of the ſame. When the counterſcarp of the ditch is reveted, or faced with maſonry, he makes ſteps at all its angles for the convenience of the troops, and the ſervice of the covert-way. Each detached piece or work ſhould, for a ſimilar reaſon, have a pair of ſtairs to lead up to it.

He makes the countermines of a place under the terreplain of the rampart, on a level with the ditch, and about ten feet diſtant from the *revetement*, to which they are parallel, and have a communication with it through ſmall arched *heads*, or paſſages. From the countermines of the place men go down into the caponieres, and then up into the countermines of the covert-way, from which *heads* or paſſages are carried on under the field to *fourneaux* or ſmall mines, made for blowing up the beſieger's works, and retarding their approaches.

He was of opinion, that when an eminence falls gradually from its ſummit towards the glacis of a place, works ought to be made one before another, with their ſaliant or flanked angles ſufficiently raiſed; that the moſt diſtant ought to cover all the reſt, and draw its defence from them; and that they ought all of them to be built in ſuch a manner, as to prevent an enemy from making a retrenchment in the firſt, without being expoſed to the fire of the ſecond; or in the ſecond, without being expoſed to that of the third, and ſo on.

The glacis ſhould as often as poſſible be compoſed of pebbles, or of ſtones covered with turf, ſince the beſiegers can work but ſlowly in it when ſo made, and the parapets thrown up in it by the pioneers, are apt to occaſion their being killed or wounded, as the cannon-ſhot of the place ſtriking againſt, ſcatter the ſtones, and make them fly in different directions.

He obſerves, that the bridges of his curtains do not interfere with the fire from his flanks along the faces of the baſtions in the ditch, and he prefers that ditch which, by means of ſluices, can be filled or emptied at pleaſure.

The conſtruction of the Chevalier de Ville's method of fortifying is the following.

He begins inwards, and conſtructs outwards. He makes his flanks equal to the demi-gorges, and each of them equal to a ſixth part of the ſide of the figure or polygon on which he conſtructs. In the ſquare and pentagon, he determines the flanked angle or ſaliant angle of the baſtion by a raſant line; but in all figures and polygons of a greater number of ſides than five, he makes it equal to a right angle, by deſcribing a ſemicircle, as E G N on a right line, (*fig.* 10.) E N joining the epaules E and N, thereby making a ſecond flank, as D I, C H, which increaſes with the number of ſides in the figure or polygon. The length A G, of the capital of the baſtion is, in this caſe, equal to the gorge line C P, or the diſtance between the points where the flanks of the baſtion meet the adjoining curtains, a circumſtance which furniſhes an eaſy method of finding the points of the baſtions.

In conſtructing his caſemates, or retired flanks and orillons, he ſets of from C and D, on the flanks C E, D F, lines equal each to a third part of C E or D F, or of the demi-gorge, as D *a*, for inſtance, on D F. He alſo takes F *b* in the face H F produced, equal to D *a*, and then draws *b c* parallel to F *a*, to meet a right line joining *a*, and G the point of the oppoſite baſtion. Then *b c* is the front of the orillon, when it is made ſquare. But when he makes it round, he deſcribes two arcs from *b* and *c*, as centres, with a radius equal to *b c*, and from their interſection as a centre through the points *b*, *c*, he deſcribes the arc of his orillon.

The calculation of the lines and angles, according to his conſtruction, may be made in the following manner.

If we ſuppoſe A B to be the ſide of a hexagon, the angle A O B of the centre will be equal to 60 degeees, and the angle B A S, or A B T, of the figure, equal to 120°. And as the flank is by the conſtruction perpendicular to the curtain, the angle E C D of the flank is, of courſe, equal to 90 degrees. But as the flanked angle E G N is alſo equal to 90 degrees, the half of it, A G I, is equal to 45 degrees, and conſequently the angle *diminué* A I G, being equal to half the exceſs of the angle of the polygon above the flanked angle, is equal to 15°. And the angle of the epaule is of courſe equal to 105°.

Wherefore, if A B be aſſumed of a given length, whether equal to 120 toiſes, or otherwiſe, the capital A G of the baſtion, and the gorge-line C P, which is equal to it, is eaſily found by the following analogy, and the iſoſceles triangle C A F.

As the ſine of the angle A C P, or A P C, half the exceſs of 180° above the angle of the polygon, or half the angle of the centre,
Is to the ſine of the angle of the polygon or centre,
So is the flank of the baſtion or $\frac{AB}{6}$
To the gorge-line C P, or capital of the baſtion A G.

And the raſant line G I, in the oblique-angled triangle A G I, is found by this analogy.

As the ſine of the angle *diminué* A I G

Is to the ſine of the angle G A I, or its ſupplement O A I, half the angle of the polygon,
So is the capital A G of the baſtion
To the raſant line G I.

And the line A I is obtained from the ſame triangle, by this analogy.

As the ſine of A I G the angle *diminué*
Is to the ſine of A G I, half the flanked angle,
So is the capital A G of the baſtion
To the line A I.

From which, if there be taken the flank or demi-gorge, there will remain the complement C I; which, taken from the curtain C D, leaves the ſecond flank D I. The complement C I is alſo eaſily found from the right-angled triangle, E C I, by the following.

As radius
Is to the tangent of the angle C E I = 90° — the angle *diminué*,
So is the flank E C, a ſixth part of A B,
To the complement C I.

The ſide G H of the exterior polygon is determined by taking a fourth proportional to O A, A B and O A + A G.

The foregoing methods of conſtruction have been called the *French manner*, particularly thoſe of Count Pagan and Mr. Vauban, who borrowed from him the length of his perpendicular, which is the principal part of conſtruction, and that on which all the other parts chiefly depend. Vauban's method, however, has been chiefly followed on account of its plainneſs and ſimplicity, with a ſingle flank. It is proper, nevertheleſs, to give the conſtructions of ſome of thoſe methods of fortifying that have been made uſe of in other nations.

The Italians, who have not been anxious about making the flanked angle, or angle of the baſtion, either right or obtuſe, but prefer having it acute for the purpoſe of getting a ſecond flank on the curtain, have ſeveral methods of fortifying delivered by their authors, amongſt which that of Sardi has been eſteemed one of the beſt.

He begins inwards and conſtructs outwards, ſuppoſing A B equal to 800 geometrical paces or feet (*fig.* 11.). Of theſe he allows 150 for the demi-gorge A C or B D, and the ſame for the flank C E or D F, which he places perpendicularly to the curtain C D, on which he takes an eighth part D I for the ſecond flank, making I the point in the curtain, from which the raſant line drawn through E the extremity of the flank or angle of the epaule, gives the ſaliant point G of the baſtion on the lengthened radius O A. And this operation, continued round the figure or polygon, completes the conſtruction.

He makes a caſemate in each flank, capable of holding three pieces of cannon, by ſetting off from the extremity of the curtain on the demi-gorge, a line equal to a third part of the flank, and the ſame on the flank itſelf. And he makes his orillons either ſquare or round.

He places ſquare cavaliers on the middle of his curtains, of which the faces are parallel to the parapet of the rampart, and 30 feet diſtant from the ſame. In each of theſe he puts 7 pieces of cannon, three of which look into the field, and the other four towards the two adjoining baſtions to flank ſuch breaches as the beſiegers may make in the faces of them, and prevent them from giving the aſſault.

The calculation of the principal lines and angles in Sardi's conſtruction, may be made in the following manner.

Since the interior ſide A B is by ſuppoſition equal to 800 geometrical paces or feet, and the demi-gorge A C, and flank C E, each equal to 150 of theſe, the curtain C D is equal to 500, and the ſecond flank D I, which is the eighth part thereof, is equal to 62½. Conſequently the complement C I is equal to 437½ ſuch feet or paces.

But if we ſuppoſe A B to be the ſide of a hexagon, the angle A O B of the centre will be equal to 60°, and the angle S A B or A B T of the polygon will be equal to 120°. And the angle E C D of the flank is by the conſtruction equal to 90 degrees.

The angle *diminué* C I E is therefore found from the right-angled triangle E C I by this analogy.

As the complement C I
Is to the flank C E,
So is the radius
To the tangent of the angle *diminué* C I E, which is about 18° 55′. If this be added to the angle of the flank, which is equal to 90°, we get 108° 55′ for the angle C E G of the *epaule*. And if the ſaid angle *diminué* of 18° 55′ be taken from the angle O A I, or half the angle of the polygon, which is here equal to 60°, we get 41° 5′ for the angle A G I half the flanked angle. Conſequently the flanked angle is about 82° 10′.

If to the complement C I we add the demi-gorge A C, we get A I equal to 587½ ſuch feet or paces, and the raſant line G I is therefore found from the oblique-angled triangle A I G by the following analogy.

As the ſine of half the flanked angle A G I
Is to the ſine of the angle G A I, or of half the angle of the polygon,
So is the line A I
To the raſant line G I.

The capital A G of the baſtion is alſo obtained from the ſame triangle by this analogy.

As the ſine of half the flanked angle A G I
Is to the ſine of the angle *diminué* A I G,
So is the line A I
To the capital A G of the baſtion.

If to the curtain C D we add the demi-gorge A C, we get the lengthened curtain A D, equal to 650 ſuch feet or paces, and from thence by means of the oblique-angled triangle G A D the fichant line G D in the following manner.

As the ſum of the lengthened curtain and capital A D, A G,
Is to their difference,
So is the tangent of half the ſum of the angles A G D, A D G, or of one quarter of the angle of the polygon,
To the tangent of half their difference, which is found to be about 12° 31′. This taken from 30° one quarter of the angle of the polygon, or 120°, leaves 17° 29′ for the angle A D G, and added to the ſame gives 42° 31′ for the angle A G D. Wherefore,

As the ſine of the angle A D G
Is to the ſine of the angle G A D, or of half the angle of the polygon,
So is the capital A G of the baſtion,
To the fichant line G D.

The Italian writers on fortification ſeem fond of having the flanked angles, or angles of the baſtions acute, in order that the faces of the baſtions, on the ſame ſide of the place, may defend one another, and ſerve as flanks when the caſemates and flanks are battered down or ruined. But the ſecond flank on the curtain is by this conſtruction too ſmall to make the flanked angle always acute. To make it anſwer this purpoſe, it would be an improvement of it to make the ſecond flank increaſe in length, as the number of the baſtions, or of the ſides of the figure increaſes.

It is perhaps worthy of remark, that the angle A D G by this conſtitution on a hexagon, exceeds that ſubtended by the true perpendicular of a hexagon by about 17′ only.

The angles of the ſquare and pentagon are too ſmall for a ſecond flank. And the Chevalier de Ville, whoſe conſtruction much reſembles Sardi's in ſeveral reſpects, appears to have borrowed from him the idea of making his flanks equal to his demi-gorges. He takes care however to avoid ſecond flanks in the ſquare and pentagon, and in other figures to make them increaſe with the number of the ſides of the figure.

The following is the conſtruction of the Dutch method of fortifying according to Marolois.

Before he begins his conſtruction he aſcertains the magnitude of the flanked angle, or angle of the baſtion, by adding 15° to half the angle of the polygon, which makes it in the ſquare equal to 60°, in the pentagon equal to 69°, in the hexagon equal to 75°, in the heptagon equal to about 79° 17′, in the decagon equal to 87°, in the dodecagon equal to 90°, which he alſo allows for it in all figures or polygons of a greater number of ſides.

He makes the curtain I K (*fig.* 12.) equal to 36 rods of 12 Paris feet each, or 72 toiſes, the face of the baſtion A F equal to 24 ſuch rods or 48 toiſes, making the ratio of the curtain to it a ſeſquialteral one, or that of 3 to 2. He makes the flank-forming angle F M I equal to 40°, when he wiſhes to have only a ſingle flank, in order that the demi-gorge I M may be to the flank in the ratio, nearly of 6 to 5, and equal to 35° only, when he intends to have a covered flank, making then the ratio of the demi-gorge to the flank about that of 7 to 5.

Let A B be an exterior ſide. Make the angle B A O equal to half the angle of the polygon. Biſect the ſame by the right line A P. Take the angle P A E equal to 7° 30′. On the raſant line A E ſet off from A 48 toiſes for the face A F. From the epaule F draw the perpendicular F G, and produce G F indefinitely towards I, making at the point F an angle I F M of 50°. Draw through the point M, where the line F M meets the radius A O, an indefinite right line, M N, parallel to the exterior ſide A B, which will be a ſide of the inward polygon. Take the curtain I K, equal to 72 toiſes, and the line G H equal to it. Join K H, and on it take K L equal to the flank I F.* Make the demi-gorge K N equal to the demi-gorge I M, and H B equal to A G. Draw the face B L, and the capital B N, which, being produced, will meet the capital A M alſo produced in the centre O.

The calculation of the principal lines and angles of the conſtruction on the ſides of a polygon fortified, according to Marolois's method, may be made in the following manner.

If we ſuppoſe A B to be the ſide of a hexagon, we have the angle of the centre equal to 60°, the angle of the polygon equal to 120°, and conſequently O A B half the angle of the polygon equal to 60°. Wherefore O A E, half the flanked angle, is equal to 37° 30′, which taken from O A B, half the angle of the polygon or 60°, leaves 22° 30′ for the angle *diminué* E A B. But the angle of the flank is a right angle by the conſtruction. If to this then there be added the angle *diminué*, we ſhall have 112° 30′ for the angle A F I of the *epaule* or ſhoulder, from which if the angle I F M, which is equal to 50°, be taken, there will remain 62° 30′ for the angle A F M. The angle A M F is = 80°.

The capital A M of the baſtion is found from the oblique-angled triangle A M F by this analogy.

As the ſine of the angle A M F

Is to the ſine of the angle A F M,

So is the face A F of the baſtion

To the capital A M.

And the line M F is found by this analogy.

As the ſine of the angle A M F

Is to the ſine of the angle F A M,

So is the face A F of the baſtion

To the line F M.

The flank I F is found from the right-angled triangle M I F by this analogy.

As radius

Is to the ſine of the flank-forming angle I M F=40°,

So is the line F M

To the flank I F, which is equal to about 19 toiſes.

And the demi-gorge M I is found from the ſame triangle by this analogy.

As radius

Is to the ſine of the angle I F M=50°,

So is the line F M

To the demi-gorge M I, which is equal to about $22\frac{2}{3}$ toiſes, the double of which or $45\frac{1}{3}$ toiſes added to the curtain I K, which is equal to 72 toiſes, gives the interior M N, equal to about $117\frac{1}{3}$ toiſes.

The exterior ſide A B is determined by means of the line A G, which is found from the right-angled triangle A G F, by this analogy.

As radius

Is to the ſine of the angle A F G = 67° 3′,

So is the face A F of the baſtion, which is equal to 48 toiſes,

To the line A G, which is equal to about $44\frac{1}{3}$ toiſes, the double of which added to G H, that is, equal to 72 toiſes, gives $160\frac{2}{3}$ toiſes for the exterior ſide A B.

The ſecond flank E K is determined by means of the complement E I, which is found from the triangle E I F, by either of the following analogies.

As the ſine of the angle *diminué* I E F=22° 30′

Is to the ſine of the angle E F I=67° 30′,

So is the flank I F

To the complement I E.

Or, As radius

Is to the tangent of the angle E F I=67° 30′,

So is the flank I F

To the complement I E, which is equal to about $45\frac{5}{6}$ toiſes, and which taken from the curtain, which is equal to 72 toiſes, leaves $26\frac{1}{6}$ for the ſecond flank E K or I C.

The perpendicular diſtance of the interſection of the lines of defence, from the middle of the exterior ſide A B, is found by this analogy.

As radius

Is to the tangent of the angle *diminué*, which is=22° 30′;

So is half the exterior ſide A B

To the perpendicular from it to the interſection of the lines of defence, which is therefore equal to about $32\frac{1}{2}$ toiſes.

This conſtruction furniſhes an eaſy method of working on the ground, when through interruptions from buildings, hedges, thickets, &c. and from the unevenneſs and irregularity of the ground itſelf, a regular polygon cannot eaſily be deſcribed by finding the centre of the circumſcribing circle. For ſuch a polygon may be traced on the ground by means of the maſter-lines of the curtains and baſtions, ſetting off firſt ſucceſſively the angle of the polygon without any reference to the centre. This author, however, inſtead of making his flank equal to his perpendicular, as it ought to be, makes it fall ſhort of the ſame by not leſs than $13\frac{1}{2}$ toiſes.

There are other methods of conſtruction delivered by Dutch writers, which, however, are hardly deſerving of notice. And as in all their methods, they make a ſecond flank on the curtain, and for the moſt part draw at the ſame time the counterſcarp of the great ditch parallel to the faces of the baſtions, they render the defence very defective. For the branches of the counterſcarp being thus parallel to the fichant lines, will, when produced, frequently meet the curtains, and will of courſe cover the greateſt part of the ditch itſelf, from the view of the flanks of the baſtions. And as the principal part of the ditch is thus ſeen by the ſecond flanks only, which are eaſily ruined, the entrance into it is rendered eaſy to the beſiegers.

The following is the conſtruction of the Spaniſh method of fortifying.

Take the interior ſide A B (*fig.* 13.) equal to 120 toiſes. From A to C, and B to D, ſet off 20 toiſes or a ſixth part of A B, for each of the demi-gorges A C, B D. On perpendiculars to A B at the points C, D, take C E, D F, equal reſpectively to A C, B D, or to 20 toiſes each, or a ſixth part of A B. Let O be the centre of the circle, which circumſcribes the polygon, of which A B is a ſide. From D through E, and C through F, draw right lines to meet the radii O A, O B, of the ſaid circle, produced in the points G, H. Then E G, F H will be the oppoſite faces of the baſtions C E G P Q, D F H R S, and A G, B H their capitals. And the ſame conſtruction continued on the other ſides A M, M T, T V, V N, N B, completes the operation.

The calculation of the principal lines and angles of this conſtruction is made in the following manner.

Since A B is equal to 120 toiſes, and A C, B D, each equal to 20, the curtain C D is equal to 80 toiſes. And ſince C E, D F, are each equal to 20 toiſes, or the ſixth part of A B, and alſo perpendicular to A B by the conſtruction, C D is to C E as four to one, and as radius to the tangent of the angle C D E, which is therefore equal to about 14° 2′. Wherefore the angle C E D is equal to about 75° 58′, and the angle C E G of the epaule or ſhoulder is equal of courſe to about 104° 2′. Theſe angles, therefore, are the ſame in all polygons. But the flanked of conſequence, with the angles of the polygons.

Now, if we ſuppoſe A B to be the ſide of a hexagon, we have the angle A O B of the centre equal to 60°, and the angle M A B or A B N of the polygon equal to 120°. Conſequently half the flanked angle O G D or A G D, which is equal to the exceſs of O G H or O A B, half the angle of the polygon, above the angle *diminué* A D G or C D E, is equal to 45° 58′: and the whole flanked angle, or angle P G E of the baſtion, is equal to 91° 56′.

The capital A G of the baſtion, is found from the oblique-angled triangle A G D, by this analogy.

As the ſine of half the flanked angle A G D, which is =45° 58′
Is to the ſine of the angle *diminué* A D G=14° 2′,
So is the lengthened curtain A D, which is=100 toiſes,
To the capital A G of the baſtion, which is equal to about 33.73 toiſes.

And the raſant line or line of defence D G, is found from the ſame triangle by this analogy.

As the ſine of half the flanked angle A G D=45° 58′
Is to the ſine of the angle D A G=120°,
So is the lengthened curtain A D, which is=100 toiſes,
To the raſant line or line of defence D G, which is equal to about 120.46 toiſes, or $120\frac{1}{2}$ toiſes nearly.

But D E is equal to $\sqrt{\overline{CE}^2+\overline{CD}^2}=\sqrt{\overline{20}^2+\overline{80}^2}=4\sqrt{425}$ toiſes=to 82.86 toiſes nearly. Wherefore the face G E of the baſtion is equal to 37.6 toiſes nearly.

The gorge-line C Q is found from the iſoſceles triangle C A Q, by the following analogy.

As the ſine of the angle A C Q=half the angle of the centre
Is to the angle of the polygon C A Q,
So is the demi-gorge A C, which is = 20 toiſes,
To the gorge-line C Q, which in a hexagon, as this figure is ſuppoſed to be, is equal to about 34.64 toiſes.

The line O G being equal to about 153.73 toiſes, the exterior ſide G H, when A B is the ſide of a hexagon, will alſo be equal to about 153.73 toiſes. But G H is always determined by taking a fourth proportional to O A, A B, and O G.

The perpendicular diſtance K L of the interſection of the lines of defence, from the exterior ſide G H, is found by this analogy.

As radius
Is to the tangent of the angle *diminué* L G K=14° 2′,
So is G L or the half of G H, the exterior ſide,
To the perpendicular K L, which in the hexagon, as this figure is ſuppoſed to be, is equal to about 19.2 toiſes, falling ſhort of the flank C E by about 0.8 of a toiſe, or eight-tenths of a toiſe.

The Spaniards, who are rather partial than otherwiſe to obtuſe flanked angles, have no ſecond flank on the curtain, but always conſtruct their fortifications with a raſant, and never with a fichant line of defence, not minding whether the flanked angle or angle of the baſtion be acute, right, or obtuſe. Their mode of conſtruction, except as to the ſecond flanks, and the making of the flanked angle right, is the ſame with that of the Chevalier de Ville, above deſcribed, which being compounded of the Italian and Spaniſh methods, has on that account been called the compoſed draught, or the compoſed method of conſtruction.

Let A B (*Plate* VII. *fig.* 14.) be the ſide of a regular hexagon inſcribed in a circle, and equal to 160 toiſes. Set off from its extremities A and C on it A C, B D as demi-gorges, and each equal to an eighth part of A B, or to 20 toiſes. From the points C and D on right lines perpendicular to A B take C E, D F, as flanks equal each to 20 toiſes, or an eighth part of A B alſo. Take the curtains C I, D K, from the points C D, and A B, each equal to 40 toiſes, or a fourth part of the interior ſide A B; and from the points I, K, on right lines, drawn perpendicularly to A B inwards, take I L, K M, for the retired flanks, each equal to 20 toiſes, or the eighth part of the interior ſide. Join the points L, M, by drawing L M for the retired curtain. From the extremities L, M, thereof through the points K, I, draw the right lines L K, M I, which being produced, will paſs through the outward extremities E, F, of the flanks C E, D F, and will meet the lengthened radii O A, O B, in the points G, H, which will determine the ſaliant points of two of the baſtions. And a ſimilar operation continued quite round on the other ſides of the polygon, will complete the conſtruction.

As the foregoing figure is ſuppoſed to be a regular hexagon, the angle of the centre is equal to 60°, and that of the polygon to 120°. And as M L is to L I, as 40 to 20 or 2 to 1, the natural tangent of the angle *diminué* L M I, or M G H to unity, as radius is equal to $\frac{1}{2}$ or to 0.5000000, which is nearly equal to the natural tangent of 26° 34′. If this angle be taken from 60°, half the angle of the polygon, there will remain 33° 26′ for half the flanked angle, or half the angle of the baſtion. The flanked angle therefore, or the angle of the baſtion, is in a hexagon equal to 66° 52′.

Now the line G I is found from the oblique-angled triangle A G I, by this analogy.

As the ſine of 33° 26′, half the flanked angle, or A G I
Is to the ſine of the angle G A I=120°,
So is the line A I, which is equal to 60 toiſes

To the line G I, which is equal to 94.31 toiſes nearly.

And the capital A G of the baſtion is found from the ſame triangle by this analogy.

As the ſine of A G I, half the flanked angle = 33° 26′
Is to the ſine of the angle *diminué* A I G = 26° 34′,
So is the line A I, which is equal to 60 toiſes,
To the capital A G of the baſtion, which is equal to about 48.704 toiſes.

But the line I M is equal to $\sqrt{\overline{IL}^2+\overline{LM}^2}=\sqrt{20^2+40^2}=4\sqrt{125}=44.72$ toiſes nearly.

But E I is equal to I M. Wherefore G E, the face of the baſtion, being equal to G I − E I, is equal to about 49.59 toiſes, or 49.6 toiſes nearly.

The ſhort or little line of defence G M or H L, being equal to G I + I M, is equal to $\overline{94.31+44.72}$ toiſes, or 139 03 toiſes, or 139 toiſes nearly.

The lengthened radius O G, and conſequently the exterior ſide G H, when A B is the ſide of a hexagon, is equal to $\overline{160+44.72}$ toiſes, or to 204.72 toiſes.

The perpendicular diſtance of the interſection I, of the lines of defence, from the exterior ſide G H, is found by either of the two following analogies.

As radius
Is to the tangent of the angle *diminué* *i* G H = 26° 34′,
So is half the exterior ſide G H, or 102.36 toiſes,
To the perpendicular diſtance of *i* from the ſame.
Or, As radius
Is to the ſine of the angle *diminue* *i* G H = 26° 34′,
So is the little line of defence G M = 139 toiſes
To the perpendicular diſtance of the point *i* from G H, which is equal to about 62.166 toiſes.

This method was adopted for the purpoſe of conſtructing on a large front, and thereby leſſening the number of baſtions. And to keep the lines of defence G M, H L, within muſquet-ſhot, a curtain L M retired inwards, is made equal to a fourth part of the interior ſide A B, and oppoſite to the middle thereof. This manner of fortifying has been called the *ordre renforcé* or re-inforced order, concerning which ſeveral Italian and Spaniſh authors have written large treatiſes. Like moſt other writers on fortification, who have delivered different methods of conſtruction, they very abſurdly make their angle *diminué* invariably the ſame in all polygons, without aſſigning any good reaſon for doing ſo, drawn from the natures or properties of the polygons themſelves, the facility or difficulty of embracing them reſpectively, or from their relative degrees of capability of defence. In this method, the perpendicular diſtance of the interſection *i* of the lines of defence, from the exterior ſide G H, is more than thrice the length of the flank C E or D F.

Of Coehorn or Koehoorn's methods.

The famous Minno, baron of Koehoorn, who took many of the places, which the celebrated marſhal Vauban had fortified, publiſhed three methods of conſtruction, the firſt for a hexagon, the ſecond for a heptagon, and the third for an octagon. The publication of his treatiſe on fortification however took place before he had acquired that great experience, which juſtly procured him the reputation of being one of the firſt engineers, that has ever appeared in Europe; and the methods delivered in it are not reducible to practice. That he afterwards thought ſo himſelf is evident from the towns which he fortified. For if, after acquiring experience in the attack of places he had really been of opinion that the methods he had publiſhed, were capable of making ſuch a prodigious reſiſtance or defence as he endeavoured in his book on fortification to ſhew, that they were, it is a circumſtance difficult to be accounted for, that he never once thought of uſing them, when he had frequent opportunities of doing ſo. It ought alſo to be remembered, that his ſyſtem of fortification was publiſhed before the method of firing *en ricochet* was either practiſed or invented.

In his firſt method the works occupy twice as much ground as they do in Mr. Vauban's, and being entirely of earth, low, and liable to be eaſily ſurpriſed, would require thrice as many men, at leaſt, for their defence. His ſecond and third methods are, in fact, impracticable, as the fortification in each of them takes up five times as much ground as the town or place it ſurrounds.

This being the caſe, we will juſt give a general deſcription of them. In all the three he begins inwards and conſtructs outwards. The firſt he applies to a hexagon and ſuppoſes the ſurface of the water to be only about four feet lower than the level ground. In this he conſtructs from an interior ſide of 150 toiſes, from the extremities of which he ſets off on the ſame 39 toiſes for each of the demi-gorges and 80 toiſes on the lengthened radii of the hexagon for the capital of each of the baſtions. He thus leaves 72 toiſes for the length of his curtain. From the extremities of the interior ſide he takes, on the lengthened radii reſpectively, 40 toiſes for the points of interſection of the higher faces of the baſtions, which are alſo equal each to 40 toiſes, and parallel to the lower faces that are in the lines of defence. The ſpace between the lower and higher faces of the baſtions is a dry ditch, the bottom of which is only about ſix inches above the level of the water in a wet ditch. Behind the lower parapet there is a banquette of three feet and a rampart of five, and under this rampart is a ſtone gallery, that runs from one end of it to the other, and is divided into ſeveral apartments, which are ſhut with doors. There is alſo a gallery, which goes from the ſaliant angle formed by the lower faces to that formed by the higher with loop-holes at ſmall diſtances from one another, looking into the dry ditch. There are likewiſe rows of paliſades placed parallel to the higher face at the diſtance of four toiſes from them.

The great ditch is 24 toiſes broad, and its counterſcarp is parallel to the lower faces of the baſtions. The demi-gorges of the ravelin are each equal to 29 toiſes, and the faces each to 45 toiſes. The dry ditch between the lower and upper faces of it is 16 toiſes broad. The rampart is 28 feet broad, the banquette three, and the parapet 20. The lower faces are parallel to the higher ones.

The angle *diminué*, or the angle formed by the exterior ſide, and either line of defence, is in this method equal to 24° 38′ 48″.

His ſecond method he applies to a heptagon, and ſuppoſes the level of the ground to be only about three feet above that of the ſurface of the water. In it he conſtructs outwards from an interior ſide of 126 toiſes in length, from the extremities of which he takes on the ſame 30 toiſes for each of the demi-gorges. On the lengthened radii of the heptagon he ſets off 72 toiſes for the capital of each of the baſtions, at the extremities of which he draws right lines forming with the ſaid capitals angles each of 40°, and on theſe lines he ſets off 66 toiſes for the faces of the baſtions reſpectively. From the ſaliant angles of the baſtions as centres with radii equal to the diſtance from the ſame to the extremities of the demi-gorges 30 toiſes diſtant from thoſe of the interior ſides he deſcribes arcs, in which he ſets off reſpectively chords equal each to 30 toiſes, and on theſe chords deſcribes the mean flanks which are arcs of 60°.

The outline of his higher flank is 13 toiſes diſtant from that of the mean, and this flank is an arc deſcribed from the ſame centre, that the mean flank is deſcribed from, having its chord equal to 40 toiſes.

The dry ditch round the body of the place is 20 toiſes broad before the faces of the baſtions, to which its counterſcarp is parallel. There is a wet ditch before his tenailles 10 toiſes broad with two bridges at each end near the orillons, the one of which leads directly acroſs it and the other along the face of the baſtion.

The ſaliant angle of the ravelin is 125 toiſes diſtant from the curtain of the body of the place and is of 70 degrees of magnitude. The faces are each 50 toiſes long, and the faces of the redoubt in it are 16 toiſes diſtant from thoſe of the ravelin, and each 14 toiſes long. The wet ditch before the lower faces of the ravelin is 24 toiſes broad, and the work beyond that ditch, which he calls the ſecond counterſcarp, is 20, and parallel to the ditch.

The flanked angle or angle of the baſtion in this method is equal to 80°, and the angle *diminué* or the angle formed by the exterior ſide and either line of defence is equal to twenty-four degrees and two ſevenths. In his firſt method the angle of the baſtion or flanked angle is equal to 70° 4′ 24″.

He applies his third method to an octagon, of which the ſide is equal to 110 toiſes, and from which he conſtructs outwards; from its extremities he ſets off 21 toiſes for each of the demi-gorges. On the lengthened radii, or radii of the octagon produced, he ſets off from the ſaid extremities of the interior ſide 64 toiſes for the capitals of each of the baſtions, the faces of which he ſuppoſes to be each equal to 54 toiſes, and the ſaliant or flanked angle equal to 85°. He thus makes his curtain equal to 68 toiſes.

In his firſt and ſecond methods he has three flanks including that of the tenaille. But in this he has only two, the lower of which is determined or found by deſcribing an arc through the extremity of the tenaille from the ſaliant angle of the oppoſite baſtion as centre and ſetting off from the ſaid extremity in the ſaid arc a chord equal to 20 toiſes, on which an arc of 60 degrees is deſcribed for the flank. The upper flank is deſcribed from the ſame centre, that the lower one is deſcribed from through one extremity of the curtain, and its chord is equal to 30 toiſes.

The wet ditch before the body of the place is 20 toiſes broad, and its counterſcarp is parallel to the faces of the baſtions.

The capital of the detached baſtion is equal to 100 toiſes, its faces are directed towards the ſaliant angles of the inner baſtions. The dry ditch between the lower and higher faces of the detached baſtions is 20 toiſes broad; and the higher faces are parallel to the lower, and each of them 31 toiſes long. The ditch before the detached baſtions 24 toiſes broad. It is evident, that in this third method of Coehorn the angle *diminué* or the angle formed by the exterior ſide and either line of defence is equal to 25 degrees. For ſince the angle of the centre in an octagon is equal to 45°, that of the octagon is equal to 135°, from which, if the flanked angle, that by the conſtruction is equal to 85°, be taken, we get 50° for the double of the angle *diminué*, which is of courſe equal to 25°.

Of Mr. Belidor's methods.

This author delivers three methods of conſtruction, the firſt he applies to an octagon, of which the ſide is equal to 200 toiſes. In the three he begins outwards and conſtructs inwards. In the firſt he makes the perpendicular to the exterior ſide equal to 50 toiſes, the faces of his baſtion equal each to 70 toiſes, and he finds his flanks in the ſame way with Mr. Vauban in in his firſt method. He makes his baſtion with flanks equal each to about 26 toiſes. On the line joining the extremities of theſe flanks he conſtructs inwards, erecting a perpendicular to the middle thereof equal to 13 toiſes, through the inner extremity of defence and takes on them the faces equal each to 22 toiſes. The parts of the lines of defence from their interſection to the points where they terminate the flanks, are each equal to 14 toiſes. The dry ditch before this front is 10 toiſes broad at the inner extremities of the baſtion, and its counterſcarp produced terminates at the oppoſite ſhoulders. He connects the flanks of the baſtions with the curtains or lines joining the faces of the interior front by means of works in the form of arcs called ram's-horns, which are deſcribed from the middle points of the ſaid faces as centres with a radius of 25 toiſes. The ſaliant angle of the redoubt in his baſtion is in the interſection of the two adjoining curtains produced, and the faces of it terminate on thoſe of the inner front within three toiſes of the *epaules* or ſhoulders. The ditch before it is 3 toiſes broad. It has a ſtone wall in the faces from three to four feet thick with loopholes. Mr. Belidor adds no outworks to this method of conſtruction, which has certainly the advantage of all thoſe with detached baſtions. The retrenchments within are capable of a good defence, but occupy too much ground, particularly the ditches, that might be better diſpoſed of. The flanks of ſuch large baſtions as his are too ſmall. The great ditches are too large, being 20 toiſes broad at the ſaliant angles of the baſtions with its counterſcarp directed towards their ſhoulders.

In this method his angle *diminué* or the angle formed by the exterior ſide and either line of defence is equal to 26° 33′ 54″, and of courſe the angle of his baſtion or the flanked angle, as the conſtruction is applied to an octagon, is equal to 81° 52′ 12″.

His ſecond method of conſtruction he alſo applies to an octagon, of which the exterior ſide is equal to 200 toiſes, the perpendicular to which, from the middle point thereof, he makes equal to 55 toiſes. The faces of his baſtions, which are detached, are each equal to 70 toiſes, as in his firſt method. And the flanks as well as in the firſt are found in the ſame way as Mr. Vauban's.

The right line, that paſſes through the inner extremities of his baſtion, ſerves as an exterior ſide for conſtructing the inward polygon on, the perpendicular to which, at the middle point thereof, is equal to 5 toiſes, through the inner extremity of which the lines of defence are drawn. On theſe the faces are ſet off, each equal to 24 toiſes; and the flanks are chords of arcs deſcribed from the oppoſite ſhoulders of the detached baſtions as centres.

The inward polygon is in fact nothing elſe than a ſtrong wall, behind the curtain of which, and at the diſtance of about 18 feet from it, there is an epaulement or a parapet of earth 3 toiſes thick. And within the baſtions there are cavaliers, of which the fronts are circular arcs, deſcribed with a radius of from 23 to 24 toiſes. Their flanks are each equal to 7 toiſes, and their gorges to 32 toiſes each.

The counterſcarp of the ditch before this inner polygon is diſtant from it at the ſaliant angles, and is parallel to the curtain.

His tenailles, called ram's-horns, touch the outer lines of defence within three toiſes of the *epaules* or ſhoulders of the detached baſtions, and are ſo deſcribed as to meet the ſaid lines of defence inwards, beyond their interſection in the points, where the counterſcarp of the inner ditch meets the ſame.

The outline of the curtain between the ram's-horns is 9 toiſes beyond or without the inner ditch.

The exterior line, from the retrenchment within his detached baſtion is conſtructed, runs acroſs the ſame, and meets the faces thereof about 20 toiſes from the *epaules*, or ſhoulders, the perpendicular to which line at the middle point thereof is equal to 17 toiſes. Through the inner extremity of this perpendicular the lines of defence for the retrenchment are drawn. On theſe lines, from the faces of the baſtion, thoſe of the retrenchment are ſet off equal each to 20 toiſes. The chord, on which the orillon is deſcribed, is equal to 5 toiſes, as is alſo that on which the retired flank is deſcribed. Both are made according to Mr. Vauban's method. The circular curtain of this retrenchment, and the rounded part of the ditch adjoining it, are deſcribed from the ſaliant angle of the inner conſtruction next to it, with a radius of 25 toiſes. The great ditch before the ſaliant angles of the detached baſtions is 20 toiſes broad, and as it is ſuppoſed to be dry, Mr. Belidor made a *caponiere* from the curtain between the ram's-horns to the ravelin of about 18 or 20 feet wide, the parapets of which he made terminate on both ſides in a ſlope or glacis.

The capital of the ravelin he makes equal to 66 toiſes, and that of the redoubt within it equal to 30 toiſes. The faces of the ravelins are directed towards thoſe of the retrenchments within the detached baſtions, and thoſe of the redoubt within it to the ſhoulders of the ſaid baſtions. The batteries in the ravelin are retired 8 toiſes back from the faces of it. The ditch in front of the ravelin is 12 toiſes, and the breadth of that before the redoubt is equal to 7 toiſes.

The demi-gorges of the *lunettes* are each equal to 25 toiſes, and their faces are perpendicularly directed towards thoſe of the ravelin and detached baſtions. The ditch before them is 8 toiſes wide, and the batteries in them are retired 8 toiſes back from their faces, and are each of them 15 toiſes long. The covert-way is 6 toiſes broad.

In this method the angle *diminué*, or the angle formed by the exterior ſide and either line of defence, is equal to 28° 48′ 39″; and as the conſtruction is applied to an octagon, the angle of the baſtion, or the flanked angle, is of courſe equal to 77° 22′ 42″.

It is manifeſt that in this conſtruction the perpendicular to the exterior ſide, or of the great polygon, is much longer than it ought to be, ſince it exceeds the true perpendicular belonging to a polygon of 30 ſides. For the angle *diminué*, which it gives, is greater than the true angle *diminué* belonging to a polygon of 30 ſides, by upwards of one degree. And the angle of the baſtion, or flanked angle, falls ſhort of the real flanked angle in a polygon of 30 ſides, by not leſs than 33°. The baſtions are thereby made by far too large and extenſive. The great ditch appears alſo to be too wide, as the excavation of it will furniſh more earth than what is wanted for raiſing the ramparts. The works indeed, taken altogether, are too expenſive to be erected. For it would require almoſt a whole army to defend them, beſides ſuch a prodigious quantity of ſtores and ammunition, as cannot be allotted for the ſervice or defence of any one place.

Mr. Belidor applies his third method of conſtruction, as he does his firſt and ſecond, to an octagon, of which the exterior ſide is equal to 200 toiſes. But he makes the perpendicular to it at the middle point thereof equal only to 40 toiſes, which is very nearly indeed equal to the true perpendicular of an enneagon of the ſame exterior, and therefore comes nearer to the true perpendicular of an octagon than that which has been deſcribed for it by any other writer on fortification. On this account we will give the conſtruction of part of the body of the place on an octagon according to this method.

Let AB (*Plate* VIII. *fig.* 15.) be equal to 200 toiſes inſide of an octagon. Biſect AB in the point C, and draw CD perpendicular thereto. From C to D ſet off to D, equal to 40 toiſes, and from the extremities A, and B, of the exterior ſide AB, through the point D, draw the lines of defence. On them take AE and BF for the faces of the baſtions, equal each to 55 toiſes. The parts D*n*, D*r*, between the interſection, D, of the lines of defence, and the broken parts of the curtain, take each equal to 30 toiſes, and the length of each of the broken parts remains equal to 25 toiſes. The orillon is equal to 9 toiſes, and is part of a flank found according to Mr. Vauban's method. The flanks are retired 8 toiſes, and are arcs of 60° each. The outlines of the ram's-horns are 13 toiſes diſtant from one another. The paſſages at their extremities are each 3 toiſes wide. The outermoſt or loweſt is deſcribed with a radius of 30 toiſes, and the other is deſcribed from the ſame centre. By making the ſame conſtruction on two other ſides of the octagon, the poſitions of the other faces, AG, BH, of the baſtions is determined as well as the magnitude of the ſaliant angle of each. He places cavaliers in the gorges of the baſtions.

The capital of his ravelin is 44 toiſes, the demi-gorges of it are each equal to 31 toiſes, and its flanks, which are directed towards the ſhoulders of the baſtions, are each of them equal to 9 toiſes. The ditch before the ravelin is 10 toiſes wide, and the covert-way is 6 toiſes broad.

The glacis before the ſaliant angles of the baſtions is 15 toiſes broad. The demi-gorges of the places of arms are each equal to 26 toiſes, and thoſe of the redoubts or ſtone walls within them to 20. And the faces are parallel to the oppoſite demi-gorges. He makes arrows and detached redoubts after the manner of Mr. Vauban, but gives flanks to his arrows, which are parallel to the paſſages of 10 toiſes wide, that lead to them.

In this his third method of conſtruction, the angle *diminué*, or the angle BAD, or ABD, formed by the exterior ſide and either line of defence, is equal to 21° 48′ 5″, which differs from the true angle *diminué* of an enneagon by about 3 minutes only. And as it is applied to an octagon, the angle of the baſtion, or the flanked angle, is of courſe equal to 91° 23′ 50″.

It muſt be allowed that this conſtruction for the body of the place is good. The ram's-horns are unqueſtionably well contrived, and are much preferable to tenailles, as they cannot be enfiladed from any one place, as they reſiſt better, by their bending or curvature outwards, the enemies' batteries, and render the flanks much ſuperior to any batteries that the beſiegers can erect againſt them. Like a mere conſtructor on paper, however, he makes ſo many outworks, that they occupy a vaſt extent of ground, cannot be defended but by a very numerous garriſon, and uncommonly large ſupply of ammunition, artillery, and proviſions, and cannot be erected but at an immenſe expence.

The learned and ingenious Mr. Ozanam has given four methods of conſtruction, in all of which he begins inwards, and fortifies outwards, from an interior ſide of 120 toiſes, and at the ſame time places or takes his flanks on right lines drawn from the centre of the polygon through the extremities of the demi-gorges ſet off on the interior ſides.

In his firſt method he makes each demi-gorge equal to as many toiſes more than 20 as the polygon to be fortified has ſides. In the ſquare the demi-gorge is therefore equal to 24 toiſes, in the pentagon to 25, in the hexagon to 26, in the heptagon to 27, and ſo on to the decagon, in which the demi-gorge being equal by this rule to 30 toiſes, he makes it continue of this length in all higher polygons. He makes each flank equal to four times as many toiſes as the number of the ſides of the polygon, allowing 16 toiſes for it in the ſquare, 20 in the pentagon, 24 in the hexagon, 28 in the heptagon, and ſo on to the decagon, where the flank being by this rule equal to 40 toiſes, continues of that length in all higher polygons.

The angle formed by right lines from the ſaliant angle, and either ſhoulder or *epaule* of his baſtion, he calls the *flank-forming angle*.

The following is a table of the lines and angles of a fortified polygon, from the ſquare to the dodecagon, according to his firſt method of conſtruction, the inward or interior ſide being equal to 120 toiſes.

Polygons	Sides. 4	5	6	7	8	9	10	11	12
Angle of the centre	90° 0′	72° 0′	60° 0′	51° 26′	45° 0′	40° 0′	36° 0′	32° 44′	30° 0′
Angle of the polygon	90° 0′	108° 0′	120° 0′	128° 34′	135° 0′	140° 0′	144° 0′	147° 16′	150° 0′
Flank-forming angle	14° 2′	13° 1′	11° 53′	10° 36′	10° 2′	9° 21′	8° 44′	7° 50′	7° 22′
Angle of the flank	120° 58′	112° 59′	108° 7′	105° 7′	102° 28′	100° 39′	99° 16′	98° 32′	97° 58′
Angle diminué	9° 42′	13° 19′	16° 49′	20° 14′	23° 46′	27° 16′	30° 43′	30° 49′	31° 16′
Angle of the epaule	130° 40′	126° 18′	124° 56′	125° 21′	126° 14′	127° 55′	129° 59′	129° 21′	128° 54′
Flanking angle.	160° 36′	153° 22′	146° 22′	139° 32′	132° 28′	125° 28′	118° 34′	118° 22′	117° 28′
Flanked angle	70° 36′	81° 22′	86° 22′	88° 6′	87° 28′	85° 28′	82° 34′	85° 38′	87° 28′
	Toiſes. Feet.								
Demi-gorge	24 0	25 0	26 0	27 0	28 0	29 0	30 0	30 0	30 0
Curtain	72 0	70 0	68 0	66 0	64 0	62 0	60 0	60 0	60 0
Flank	16 0	20 0	24 0	28 0	32 0	36 0	40 0	40 0	40 0
Great line of defence	117 3	117 5	119 0	120 3	122 5	126 0	129 0	127 0	125 4
Face of the baſtion	36 1	37 5	40 1	42 2	45 2	48 5	52 3	50 0	49 1
Capital of the baſtion	28 0	33 3	39 4	46 1	53 4	61 2	69 4	67 5	67 3
Little radius	84 5	102 1	120 0	138 2	156 5	175 2	194 1	217 5	231 5

The following is this conſtruction on a hexagon, of which the exterior ſide is equal to 120 toiſes.

Let A B C E F D (*fig.* 16.) be a regular hexagon, inſcribed in a circle, of which the radius, A O, is equal to 120 toiſes. From the extremities A and B, ſet off A L, B M, for demi-gorges, equal each to 20+6 or 26 toiſes. In like manner ſet off A P, C Q; B *a*, D *b*; C T, E V; E *c*, F Y; F Z, D X; equal each to 26 toiſes. From the centre O, through the points, L, M, *a*, *b*, P, Q, T, V, *c*, Y, Z, X, draw the right lines O I, O H, O *d*, O *e*, O N, O S, O *m*, O *l*, O *k*, O *h*, O *g*, O *f*, and take I L, K M, *a d*, *b e*, Q S, T *m*, V *l*, *c k*, Y *h*, Z *g*, X *f*, equal each to 6 × 4, or 24 toiſes. From the points L, M, through the points K, I, draw right lines to meet the radii O B, O A, lengthened or produced in the points H, G. From the points *a*, *b*, through the points *e*, *d*, draw right lines in like manner, and ſo on round the figure. This operation will determine the ſaliant angles of the baſtions, and all the parts of the conſtruction.

The calculation of the different lines and angles in this conſtruction may be made in the following manner.

Since A B is equal to 120 toiſes, if from it there be taken the demi-gorge A L, or B M, which is equal to 26 toiſes, there will remain 94 toiſes for the lengthened curtain, A M, or B L, from which, if 26 toiſes be taken, we get the curtain L M, equal 68 toiſes. But as this figure is a hexagon, the angle of the centre is equal to 60°, and the angle of the polygon to 120°. The little radius is alſo of courſe equal to 120 toiſes.

The angle, I L M, of the flank, or its equal, A L O, is found by means of the following analogy.

As the ſum of the ſides O L + A L = 146 toiſes,

Is to their difference O L − A L = 94 toiſes,

So is the tangent of half the ſum of the angles A L O, A O L = 60°,

To the tangent of half their difference, which is equal to about 48° 7′. This angle added to 60° gives 108° 7′ for the angle I L M of the flank, and taken from 60° leaves 11° 53′ for the flank-forming angle A O L, or A O I.

In like manner the angle *diminué*, L M I, or M G H, is found from the oblique-angled triangle I L M, by means of this analogy.

As the ſum of the ſides L M, L I, which is equal to 92 toiſes,

Is to their difference, which is equal to 44 toiſes,

So is the tangent of half the ſum of the angles L I M, L M I = 35° $56\frac{1}{2}'$,

To the tangent of half their difference, which is equal to about 19° 77′. This angle, taken from 35° $56\frac{1}{2}'$, leaves about 16° 49′ for the angle *diminué* L M I, or M G H, and added to 35° $56\frac{1}{2}'$ gives about 55° 4′ for the angle L I M; conſequently the angle G I L of the epaule is equal to 124° 56′. And if 33° 38′, which is equal to twice the angle *diminué*, be taken from 180° we get 146° 24′ for the flanking angle G *i* H, or I *i* K. Double the angle *diminué*, or 33° 38′, taken from 120°, the angle of the polygon leaves 86° 22′ for the flanked angle, or angle of the baſtion.

The angle *diminué*, 16° 49′, taken from 108° 7′ the angle of the flank leaves 91° 18′ for I L K, or I L H, the inner or inward flanking angle.

The line of defence, G M, is found from the oblique-angled triangle, A G M, by means of the following analogy.

As the ſine of A G M, half the flanked angle, or 43° 11′,

Is to the ſine of the angle of the gorge, G A M = 120°,

So is the lengthened curtain A M = 94 toiſes,

To the line of defence G M, which is equal to about 119 toiſes.

And the capital, A G, of the baſtion, is found from the ſame triangle, by means of this analogy.

As the ſine of A G M, half the flanked angle, or 43° 11′,

Is to the ſine of the angle *diminué* = 16° 49′.

So is the lengthened curtain A M = 94 toiſes,

To the capital A G of the baſtion, which is equal to about $39\frac{2}{3}$ toiſes, to which, if we add the little radius O A, which is equal to 120 toiſes, we get $159\frac{2}{3}$ toiſes, for the great radius O G, to which the exterior ſide, G H, is equal, as the figure is a hexagon. And in every polygon, the exterior ſide, G H, is a fourth proportional to the little radius O A, the great radius O G, and the interior ſide A B.

The face, G I, of the baſtion, is determined by finding the line I M from the oblique-angled triangle, I L M, by this analogy.

As the ſine of the angle *diminué* I M L = 16° 49′,

Is to the ſine of the angle I L M of the flank = 108° 7″,

So is the flank I L, which is equal to 24 toiſes,

To the line I M, which is equal to about $79\frac{5}{6}$ toiſes, and when taken from I M, the line of defence, leaves about $40\frac{1}{6}$ toiſes for G I, the face of the baſtion.

The angle A O B is called the angle of the centre.

The angle B A C is called the angle of the polygon.

The angle N G I is called the flanked angle, or angle of the baſtion.

The angle I *i* K, or G *i* H, is called the outward flanking angle.

The angle G I L is called the angle of the epaule or ſhoulder.

The angle I L M is called the angle of the flank.

The angle I M L, or M G H, is called the angle *diminué*.

The angle A O L is called the flank-forming angle.

P N G I L is called a baſtion.

A P, or A L, is called the demi-gorge of the baſtion.

The line joining the points P, L, is called the gorge of the baſtion.

The angle I L K, or I L H, formed by the flank I L and the line of defence L H is called the inner flanking angle.

A B is called the inward or interior ſide.

G H is called the outward or exterior ſide.

O A is called the little radius.

O G is called the great radius.

I L, or K M, is called a flank.

L M is called the curtain.

A M, or L B, is called the lengthened curtain.

G M, or L H, is called a line of defence.

A G is called the capital line, or capital of the baſtion.

A I, or H K, is called the face, or *pan* of the baſtion.

The flank I L is called right flank, when it makes a right angle with the curtain; oblique flank when it makes an oblique angle with the ſame; and acute flank when it makes an acute angle with the curtain; as it does by Errard's method in figures up to the octagon. When the orillon is rounded or formed by the arc of a circle, it is called a round orillon, and when it is rectilinear, or formed by the face of the baſtion, produced a few toiſes beyond the *epaule*, and a right line drawn from the extremity of the ſaid prolongation, either parallel to the flank, or nearly ſo, it is called a ſquare orillon. It is made for the purpoſe of covering part of the flank, which for that reaſon, or in order to be the more effectually covered, is taken a few toiſes inwards from the flank itſelf towards the centre of the baſtion, and is generally made in an arc of a circle, though it would be better in a right line, or on the chord of an arc. It is on this account called the *retired*, or *covered flank*, and ſometimes the *caſemate*, and *place-baſſe*. And its depth, or enfoncement on the line of defence, produced beyond its interſection with the curtain, as well as its diſtance from the outſide of the orillon, is called the *retirade* or *retrenchment of the flank*, or the *platform of the caſemate*.

The line Q S is called flank, becauſe it defends the face G N of the oppoſite baſtion. For, in fortification, *to flank* has the ſame meaning or ſignification with the phraſe *to defend*. When the line G Q is not compoſed of the face G N of the baſtion, and a prolongation thereof to the angle Q of the flank, it is called *flank-fichant*, becauſe a muſketeer, at its extremity Q, can fire, or *ficher*, as the French term it, at or againſt any part of the face G N. Hence the line Q G, drawn from the ſaid extremity Q of the flank, is called the *fichant-line of defence*, and ſometimes only the *fichant-line*. It is alſo called the *great line of defence*. But when the face, G N, of the baſtion produced, meets the curtain Q P, in any point, R, between the points Q and P, or in any point R nearer to the ſaid baſtion, the line G R is called the *raſant-line of defence*, or ſimply the *raſant-line*, and alſo the *little line of defence*, being ſhorter than the line G Q, becauſe a muſketeer cannot from the point R fire at or againſt any part of G N, the face of the baſtion, but can only raſe or fire along it. The part Q R of the curtain intercepted between the lines G Q, G R, is called the *ſecond flank*, as alſo the *fire* or *the curtain*, becauſe from every point in it, except the extremity R, one may ſhoot or fire againſt every part of the face G N. Second flanks are not always, nor indeed frequently, made. And when there are none, there are no *fichant lines*, but only *raſant-lines of defence*, in which caſe the flanks are called *raſant flanks*, becauſe from their extremities, that join the curtains, one can only raſe or fire along the faces of the oppoſite baſtions, but from any intermediate points between thoſe extremities and the *epaules*, he can fire at or againſt the ſaid faces. The flanks form the principal defences, ſince an enemy cannot, whilſt they remain entire, approach the body of the place. And they are, for that very reaſon, the parts which he firſt endeavours to deſtroy, in order to facilitate his paſſage of the great ditch.

The angle ILM, which the flank IL makes with the curtain LM, is called the *angle of the flank*, and the angle GIL, which the flank IL forms with the face GI of the baſtions, is called the *angle of the epaule*, or ſimply the *epaule*, from which comes the word *epauler*, to cover on one ſide, or to cover the flank or the ſhoulder of the beſieged in ſuch a manner, that he cannot be ſeen or diſcovered on that ſide from without. The face GI, which thus covers the *epaules* or ſhoulders of thoſe who aſſiſt in defending the place in the flank IL, is therefore called *epaulement*. The point or angle A, of the inward or interior polygon, is called the centre of the baſtion.

When the flank, IL, is on a right line, drawn from the epaule I, to the centre O of the polygon, as it is in all his four methods of conſtruction, it forms, when produced to the ſaid centre O, an angle AOL, which is called the *flank-forming angle*. The angle IGN, which the two faces GI, GN, form at the point G of the baſtion, is called the flanked angle, or angle of the baſtion, becauſe it is flanked or defended by the two oppoſite flanks QS, MK. The right line GH, drawn from one flanked angle to another, and which marks the diſtance between them, is called the *baſe-line*, and the ſide of the outward or exterior polygon, which in regular conſtruction is always parallel to AB, the correſponding ſide of the inward or interior polygon. A re-entering angle is that which retires inwards; and in terms of fortification it is called a *tenaille-angle*, or ſimply a *tenaille*. And ſuch of them as are formed by the meeting or interſection of two raſant lines, making an obtuſe angle, are called *flanking angles*, as for inſtance the angle G*i*H; and the lines G*i*, H*i*, forming it, are alſo called *tenailles*. The angle G*i*H is alſo called the *outward flanking angle*, to diſtinguiſh it from the angle ILH, formed by the flank IL, and the raſant line GL, when the flank is raſant, which is called the *inward*, or *inner flanking angle*; or from the angle GRQ, when there is a ſecond flank RQ, which is alſo called an *inward flanking angle*.

The raſant lines, GM, HL, always make acute angles with the curtain LM, either of which, as IML or GML, is called the *angle diminué*, or *angle diminiſhed*, and is equal to the angle MGH, which GM forms with the baſe-line, or exterior ſide GH. The angle GAL, formed by the capital AG and the demi-gorge AL, is called the *gorge-angle*, or angle of the gorge, and is always equal to the exceſs of 180° above half the angle of the polygon OAB; which half angle is called the *baſe-angle*.

In his ſecond method of fortifying or conſtructing, he ſuppoſes the demi-gorges to be the ſame as in his firſt method: but inſtead of making each flank equal, as in it, to four times as many toiſes as the number of the ſides of the figure or polygon, he, in this, makes each flank equal to 10 toiſes, together with twice as many more as the figure or polygon has ſides. He thus allows 18 toiſes for each flank in the ſquare; 20 for each in the pentagon; 22 in the hexagon; 24 in the heptagon; 26 in the octagon; 28 in the enneagon; and 30 in the decagon, in which the flank and demi-gorge being equal to each other, and to 30 toiſes reſpectively, he makes them continue ſo in all higher polygons.

But as it happens by this method of conſtruction, that in the octagon, and all the higher polygons, the flanked angle or angle of the baſtion becomes obtuſe, in order to limit it to a right angle, he deſcribes on a right line, joining the epaules or outer extremities of the flanks of each baſtion, a ſemicircle, which occaſions a ſecond flank upon the curtain, and two lines of defence, one raſant and the other fichant.

The calculation of the principal lines and angles in this conſtruction is eaſily made.

In his third method of conſtruction he makes his demi-gorges, as in the ſecond, of the ſame length as in the firſt, and his flanks of the ſame length as in the ſecond: but inſtead of limiting the flanked angle or angle of the baſtion to a right one, by ſuppoſing a ſemicircle to be deſcribed on a right line, joining the two epaules, he ſuppoſes it to remain always acute, by making the capital AG equal to the gorge-line PL.

The calculation of the principal lines and angles is eaſily made on this ſuppoſition.

In his fourth method he has no ſecond flanks, but makes all the defences raſant. He conſiders this method as more general than the three foregoing ones, which it certainly is, ſince it does not limit the lengths either of the demi-gorges or of the flanks, which, in this as well as in the others, are always on right lines, drawn from the centre of the polygon, through the extremities of the demi-gorges. And although the demi-gorges become greater with the number of the ſides of the polygon, they increaſe ſo ſlowly, that in one of 60 ſides the demi-gorge is only equal to about $37\frac{1}{2}$ toiſes. The following is his conſtruction for this method.

From the centre O of the polygon or figure, draw a right line perpendicular to the inward or interior ſide AB. Divide this perpendicular into ſuch a number of parts, as exceeds the number of the ſides of the figure or polygon by unity. Set off two of thoſe parts from each extremity of the inward or interior ſide, which is always ſuppoſed to be equal to 120 toiſes for each demi-gorge, and take three of them from the ſaid extremities on the little radii produced for the capital of each baſtion. Then, from the outer extremities G, H, of theſe capitals, which are the points of the baſtions, draw right lines to the points M, L, where right lines, drawn from the centre through the extremities M, L, of the demi-gorges, interſect the interior ſide. And theſe raſant lines, ſo drawn, will determine both the faces GI, HK, and the flanks IL, KM.

By this conſtruction, which is very ſimple and eaſy, the flanked angle or angle of the baſtion begins to become obtuſe in the enneagon, where it is equal to about 92° 6′, and grows more and more ſo in the higher polygons. This angle, however, increaſes but ſlowly, or at the rate of about one degree in each ſucceſſive polygon, amounting in the dodecagon to about 96° 26′.

The calculation of the principal lines and angles, in this conſtruction, is eaſily made in the following manner.

The perpendicular, from the centre O of the polygon to the inward or interior ſide AB, is found by this analogy.

As radius

Is to the tangent of the angle $OAB = 60°$,

So is half the interior ſide AB, or 60 toiſes,

To the perpendicular from O to AB, which is equal to about 104 toiſes. Wherefore the gorge AL being, by this conſtruction, equal to two-ſevenths of this perpendicular, is equal to about $29\frac{2}{3}$ toiſes; and the capital AG, being equal to three-ſevenths of it, is equal to about $44\frac{1}{2}$ toiſes. The lengthened curtain AM is conſequently equal to about $90\frac{1}{3}$ toiſes. Wherefore the angle *diminué* AMG, or IML, is eaſily found from the oblique-angled triangle AMG, by this analogy.

As the ſum of the ſides AM, AG, which is equal to $134\frac{5}{6}$ toiſes,

Is to their difference, which is equal to $45\frac{5}{6}$ toiſes, So is the tangent of half the angle OAM, or 30°,

To the tangent of half the difference of the angles AGM, AMG, which is equal to about 11° 6′. Conſequently the angle AGM, or half the flanked angle, is equal to about 41° 6′, and the angle *diminué* LMI to about 18° 54′. Wherefore the flanked angle, or ſaliant angle of the baſtion, is equal to about 82° 12′, to which adding the angle of the centre, or 60°, we get the flanking angle G*i*H, equal to about 142° 12′.

The angle ILM, in this conſtruction, is obtained by means of the following analogy.

As the ſum of the perpendicular from O to AB and half LM, or $134\frac{1}{3}$ toiſes,

Is to their difference, which is equal to $74\frac{2}{3}$ toiſes, or as 403 to 224,

So is the tangent of 45°, which is equal to radius,

To the tangent of 28° 42′, which added to 45°, gives 73° 42′ for the angle OLM, and conſequently 106° 18′ for the angle ALO, or its equal ILM, the angle of the flank; to which if the angle *diminué* LMI = 18° 54′ be added, we get the angle GIL of the epaule, equal to 125° 12′. And if from the angle OLM there be taken the angle OAB, or half the angle of the hexagon, we get 13° 42′ for the flank-forming angle AOL.

The flank IL is found from the triangle ILM by this analogy.

As the ſine of the angle LIM, which is equal to about 54° 48′,

Is to the ſine of the angle *diminué* IML, which is equal to about 18° 54′,

So is the curtain LM, which is equal to about $60\frac{2}{3}$ toiſes,

To the flank IL, which is equal to about 24 toiſes.

And the perpendicular diſtance of the interſection *i* of the lines of defence, from the exterior ſide GH, is found by this analogy.

As radius

Is to the tangent of the angle *diminué* *i*GH = 18° 54′,

So is the half of the exterior ſide GH, which is equal to about 82.25 toiſes,

To the perpendicular diſtance of *i* from GH, which is equal to about 28.1605 or 28.16 toiſes nearly, exceeding the flank by 4.16 toiſes.

Mr. Muller, in his "Elements of Fortification," has delivered what he is pleaſed to call a new conſtruction. It differs, however, from Mr. Vauban's firſt method only in the following particulars.

1ſt. Inſtead of ſuppoſing, like Vauban, each flank to be the chord of an arc deſcribed from the ſhoulder or *epaule* of the oppoſite baſtion as centre, he ſuppoſes it to be the chord of an arc deſcribed from the interſection of the line of defence and counterſcarp produced.

2dly. He makes his retired flanks rectilinear, inſtead of making them in circular arcs.

3dly. Inſtead of uſing Vauban's tenailles before the flanks, he places ram's-horns before them.

4thly. He makes his orillon 5 toiſes long only, inſtead of 9, like Mr. Vauban.

Laſtly. Inſtead of drawing the right line, which terminates the retired flank from the ſaliant angle of the oppoſite baſtion, like Mr. Vauban, he draws it from a point on the face 5, or rather 10, toiſes within the ſaid angle.

For, in his conſtruction of this method, he begins, like Vauban, in his firſt method outwards, and conſtructs inwards. Like him he alſo ſuppoſes the exterior ſide of the polygon to be equal to 180 toiſes; and after obſerving that the perpendicular may be of any length, as the 6th, 5th, or 4th part of that ſide, he, like him, alſo fixes on 30 toiſes for its length. Like him alſo he makes the face of his baſtion equal to 50 toiſes, or to $\frac{2}{7}$ths of the exterior ſide.

He determines the ſaliant angle of his ravelin in this manner: he ſets off on the face of his baſtion from 12 to 15 toiſes from the ſhoulder or epaule, and from the oppoſite angle of the flank as centre, with the diſtance therefrom on the line of defence to the extremity of the line, ſet off from the ſhoulder on the face of the baſtion, he interſects the perpendicular to the exterior ſide, produced beyond it outwards.

He alſo gives the conſtruction of a place with detached baſtions from an inward or interior ſide of 130 toiſes, applied to an octagon, in which he ſubſtitutes ſmall baſtions inſtead of Vauban's tower-baſtions. In this method, he makes the demi-gorges of his ſmall baſtions each equal to 12 toiſes, the capitals of his detached baſtions each equal to 55 toiſes, and their faces equal each to 60 toiſes. He determines the ſaliant angle of his ravelin, by deſcribing from the extremity of the flank, as centre, through a point in the face of the oppoſite baſtion, about 20 toiſes from the ſhoulder, an arc to interſect the right line, in which is the capital of the ravelin.

He likewiſe gives the conſtruction of a place with detached orillon-baſtions, beginning outwards, and conſtructing inwards from an exterior ſide of 200 toiſes, and applying it alſo to an octagon.

He makes his perpendicular, in this conſtruction, equal to 40, or a fifth part of the exterior; the faces of his baſtions equal each to 55 toiſes; the radius of the arc, that ſerves to determine the poſition of his flank, equal to 22 toiſes; the width of the ditch of the ſaliant angles equal to 16 toiſes; his orillon equal to 5 toiſes; and he keeps his flank retired 5 toiſes.

The marquis de Montalembert has publiſhed a large treatiſe on fortification, in which he makes much uſe of caſemates and arches ſo much condemned by the Chevalier de Ville. His conſtruction is in fact the ſame with Mr. Blondel's, applied to a right line or polygon, of an infinite or indefinite number of ſides. For in this extreme caſe, which is of all others the moſt defective, Mr. Blondel's conſtruction leaves no curtain, but gives the perpendicular equal to half the exterior ſide, and the angle *diminué* equal to 45°. In deſcending, however, from the right line or polygon of an indefinite number of ſides, Mr. Blondel's conſtruction affords a curtain, which gradually increaſes as the number of the ſides of the polygon decreaſes, whilſt the angle *diminué* at the ſame time gradually decreaſes, which in a hexagon, by his rule for determining it, *viz.* by taking from 45°, a third part of the angle of the centre of the polygon, is equal to 25°. But the marquis de Montalembert makes his angle *diminué* in every polygon, and on all occaſions, invariably equal, to 45°. His conſtruction is formed by the placing of triangles contiguous to one another, or by the juxtapoſition of the angles at the baſes of triangles in ſuch a manner, as to make the other ſides form re-entering angles equal each to a right angle, from which circumſtance it is called *la fortification perpendiculaire.* It therefore affords no curtains or baſtions, but when the ſection is of only an ordinary height, it neceſſarily creates dead parts from the re-entering angles quite to the ſaliant ones, or throughout its whole extent.

It may indeed be alleged, that theſe dead parts can be removed by caſemates in the revetements, counterſcarps, caponiers, &c. &c. and no doubt they may. But what good reaſon can be aſſigned for adopting a mode of conſtruction, which creates every where thoſe very defects, which in conſtructing the body of any place, it has hitherto been the firſt object and principal buſineſs of every fortifier to avoid, and they then having recourſe to a number of expenſive, and otherwiſe unneceſſary, contrivances, merely to get rid of the defects thus created.

As we underſtand that this ſyſtem of fortification has been much diſapproved of by ſome of the ableſt engineers, on the Continent of Europe; and as the late duke of Richmond, when maſter-general of the ordnance, was ſo partial to it, that it was with much difficulty and after a great deal of diſcuſſion, that the engineers in the Portſmouth diviſion, could perſuade him to adopt Vauban's firſt method in preference to it, for the new pentagonal fort, that has been erected on Portſea iſland, near Lancaſtown harbour; a candid and impartial compariſon between theſe two methods of conſtruction may not be uſeleſs to profeſſional men, or unacceptable to the public. But we cannot make a compariſon between them more ably, correctly, and ſcientifically, than it is drawn in an anonymous publication of 1794, re-publiſhed in 1805, in the following words.

"It is manifeſt then, that after a work is once adapted to the ground it is to occupy, &c. the firſt conſideration is to conſtruct it in ſuch a manner, as to leave no dead parts; that is, to leave no ſuch parts as cannot be ſeen, fired on, or flanked from ſome other parts. That this is a fundamental maxim, and ought to be a primary object of attention in the conſtruction of every work, is manifeſt from this circumſtance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be raiſed along the exterior ſides of figures themſelves, or the curves circumſcribing them, as along the ſeveral parts of thoſe figures, into which the ſides are uſually broken for this purpoſe. The ſtrength of a work, indeed, depends chiefly on its flanks; ſince an enemy cannot approach the body of the place, whilſt the flanking defences remain entire. But if there be dead parts, the moment an enemy gets to them, he finds himſelf in a ſtate of ſecurity, and out of the reach of the beſieged's fire. An idea therefore of the neceſſity of avoiding them has always made ſuch a forcible impreſſion on the minds of able fortifiers, as to induce them to limit the heights of ſections. For even when the ſide of a polygon is 180 toiſes long, and is broken into two demi-baſtions, and a curtain with flanks, if the ſection of the work be very high, the guns in theſe flanks cannot ſee or ſcour the ditch but at too great a diſtance. When it is only of an ordinary height, it is wel lknown that the guns in the flanks do not ſee the ditch effectually nearer than the interſection of the lines of defence, which in Vauban's conſtruction is 44.8683 toiſes, or 45 toiſes nearly from the ſhoulders of the baſtions, and 40.2632, or 40 toiſes and a quarter nearly from the re-entering angles formed by the curtain and flanks. When the exterior ſide, therefore, is leſs than 180 toiſes, the ſection ought to be kept proportionally lower, provided only it be not ſo low as to expoſe the body of the place to ſurpriſe. But if it once be admitted as a maxim, that a fortification ought to be conſtructed without the leaſt regard to any flanking defence, and that the avoiding of dead or unſeen parts is an object not worthy of attention, it is evident that the rectilinear and curvilinear are greatly preferable to the zig-zag or triangular conſtruction formed by conſtituting triangles on the ſides of any right-lined figure or polygon. The fire from a ſtraight line is the beſt of the direct kind that can be obtained, being equally and uniformly diſtributed. And the enemy cannot advance againſt it directly, without a good deal of delay, inconvenience, and trouble, but muſt carry on his approaches ſomewhat in the way commonly practiſed, till he gets to the dead parts in front of it: when, unleſs contrivances be made uſe of that have no natural or inſeparable connexion with the conſtruction itſelf, it will ceaſe to be formidable for want of flanking defences. This obſervation likewiſe holds good in a great meaſure with regard to regular curves, from which the fire is alſo regularly diſtributed. The interior area too in each of theſe comprehended within the ſame enceinte, length of encloſure, or extent of rampart, is much greater than in the triangular conſtruction, which naturally, inſtead of producing any fire that is direct or at right angles to the exterior ſides, produces no good flanking one for itſelf, but cauſes a continuity of dead parts, when the ſection is high and the lines of defence but ſhort, to reign throughout its whole extent. An enemy can approach it without annoyance from the beſieged in lines biſecting either the ſaliant or re-entering angles, or in ſhort in lines directed to any intermediate points whatever between theſe angles.

It muſt therefore be allowed, that the triangular conſtruction, whether the re-entering angles be right ones (as in the "Fortification perpendiculaire" of the marquis de Montalembert), or acute or obtuſe ones, is naturally the moſt defenceleſs and ill contrived of any, that can poſſibly be thought of or conceived: for it creates dead parts throughout the whole extent almoſt of the work, and is equally deſtitute of flanking fires for itſelf, and of a good or well diſtributed direct one againſt the enemy.

The marquis, fig. 4, planche 15, vol. i. of his performance, gives what he calls his regular conſtruction in a dodecagon, of which the exterior ſide is 180 toiſes. The radius of the circumſcribing circle is of courſe equal to 347.733297 or 347.7333 or 348 toiſes nearly, and the perpendicular diſtance from its centre to the exterior ſide 335.884572, or 335.8846, or 336 toiſes nearly. Conſequently the annular area occupied by his conſtruction is equal to that of the inſcribed circle, in the circumference of which are his re-entering angles of 90°, or which comes to the ſame thing, to half the area of the circle circumſcribing the dodecagon. But if Vauban's conſtruction be made on the ſides of the ſame figure, the annular area occupied by it will be to that of the inſcribed circle, to which the curtains are tangents at the points, where the perpendiculars produced meet them, as 34980.228 to 85938.24, or as 17490 to 42969 nearly, or in ſmall numbers as 20 to 49 nearly.

The exterior area between the conſtruction and the ſides of the dodecagon in Momtalembert's method is to that in Vauban's as 8100 to 4270.2687, or in ſmall numbers, as 19 to 10 nearly; and as both the ſaliant and re-entering angles in the former are leſs than in the latter, this difference of loſt area will be conſiderably increaſed in practice. For in the marquis's conſtruction, each of the ſaliant angles contains 60 degrees, and each of the re-entering ones 90; whereas in Vauban's the ſaliant angle of each baſtion is 113° 7′ 48″, and each of the re-entering ones formed by the flanks and curtains is 99° 13′ 3″.

Montalembert's conſtruction gives the enceinte or boundary of the body of the place equal to 3054.70128 toiſes, exceeding Vauban's, which is equal to 2771.2836, by 283.41768 toiſes.

When he inſerts or intercalates triangles having their ſaliant angles right ones and in ſtraight lines, as in figures 3, 5, 7 and 8, planche 15, after the method pointed out in fig. 1, he loſes ſtill more area in proportion to the interior ſpace. And the very circumſtance of his having recourſe to different centres of conſtruction, even on figures that are regular, is ſufficient to create a ſuſpicion, that he did not underſtand even his own method in its full extent.

Although he muſt certainly be conſidered as a very ſhallow and ſuperficial geometer, the reaſon for his not fixing on any polygon under a dodecagon for illuſtrating his regular conſtruction, is very obvious; for no regular figure of a ſmaller number of ſides, will by it give ſaliant angles of ſixty degrees, which is the ſmalleſt angular magnitude that engineers have generally reckoned admiſſible in fortification. I can ſee no good reaſon, however, (ſays our author) for his abandoning regular polygons, when he has occaſion for more triangles than twelve, and by way of interpolation inſerting the additional ones to this number between right lines parallel to the ſides of triangles, ſquares, or rectangles; ſince a conſtruction on the ſides of a regular polygon furniſhes much more interior area, with a comparatively but trifling increaſe of length in the enceinte or encloſure of the body of the place.

The compariſon, which he draws, p. 197, (illuſtrated by fig. 9, planche 15.) between Vauban's method on the ſides of a ſquare, of which each is equal to one hundred and eighty toiſes, and his own on the ſides of a dodecagon inſcribed in the circle circumſcribing this ſquare, is a very improper and unfair one. In this figure, each of thoſe lines, which he calls his lines of defence, is equal to 46.5874 toiſes, and muſt, with a ſection of an ordinary height, have dead parts in front of it throughout its whole extent. Each of the ſides is equal to 65.8846 toiſes very nearly, and not to 66 toiſes one foot, as from his ſcale he erroneouſly ſtates it to be. The moſt candid and impartial mode of comparing theſe two methods of conſtruction together is to ſuppoſe both to be made on the ſides of one and the ſame figure. The marquis's conſtruction, however, on the ſides of a ſquare, neither leaves interior area nor ſaliant angles. For its re-entering angles meet in the centre of the circumſcribing circle. But as in it the lines of defence when equal form angles of 45° with the exterior ſide, each of the ſaliant angles, which it gives in any polygon, is equal to the exceſs of the angle of that polygon above 90°; or which comes to the ſame thing, to the exceſs of the re-entering angle formed by the lines of defence above the angle at the centre of the figure, ſince the exceſs of the angle of any regular polygon above 90° is equal to the exceſs of 90° above the angle at the centre of the circumſcribing circle ſubtended by one of its ſides. Conſequently, when the polygon has an indefinite number of ſides, or becomes a ſtraight line, the ſaliant angle is equal to ninety degrees. Thus a ſquare with this conſtruction gives no ſaliant angle at all; a pentagon one of 18 degrees; a hexagon one of 30 degrees; a heptagon one of 38 degrees and four ſevenths; an octagon one of 45 degrees; an enneagon one of 50 degrees; a decagon one of 54 degrees; an endecagon one of 57 degrees and three elevenths; a dodecagon one of 60 degrees; a polygon of 18 ſides one of 70 degrees; a polygon of 36 ſides one of 80 degrees; and ſo on indefinitely. By this conſtruction on a pentagon, of which the ſide is equal to 180 toiſes, the re-entering angles come within 34 toiſes of the centre of the circumſcribing circle; and within 19, if the exterior ſide be only equal to a hundred toiſes. How little interior area then would have been left, had this conſtruction been made uſe of for the new pentagonal work on Portſea iſland, called Fort Cumberland, of which one of the exterior ſides is equal to 120 fathoms, and each of the other four to a hundred! Even on a hexagon, of which the ſide is equal to 180 toiſes, it brings the re-entering angles within 66 toiſes of the centre of the circumſcribing circle, and gives the annular area occupied by it to the area of the inſcribed circle as $2\sqrt{3}$ to $4-2\sqrt{3}$, or as 6.4641 to 1, or in ſmall numbers as thirteen to two nearly. If it be even made on parts of one and the ſame ſtraight line as exterior ſides, of which each is equal to 90 toiſes only, the perpendicular diſtance between that line and the right line paſſing parallel to it through the re-entering angles exceeds that between the parallel right lines, limiting Vauban's conſtruction on parts of one and the ſame ſtraight line as exterior ſides equal each to 180 toiſes, or two of the others, by 2.2676 toiſes, and only becomes equal to it, when the exterior ſide is reduced to 85.4648 toiſes.

The angle (108°) of a pentagon exceeds 90° by 18°, which are equal to the exceſs of 90° above (72°) the angle of the centre. But 18° are equal to $90° \times \frac{1}{5}$ or $360° \times \frac{1}{4 \times 5}$. In like manner the exceſs of (120°) the angle of a hexagon above 90° is equal to 18° + 12° (= 30°) the exceſs of 90° above (60°) the angle of the centre, that is, to $360° \times (\frac{1}{4.5} + \frac{1}{5.6})$. Wherefore we get $360° \times (\frac{1}{4.5} \times \frac{1}{5.6} + \frac{1}{6.7} \times$, &c. indefinitely or *ad infinitum*) $= 90°$, and of courſe $\frac{1}{4.5} + \frac{1}{5.6} + \frac{1}{6.7} +$, &c. *ad infinitum* $= \frac{1}{4}$. Whence it is obvious, that methods of ſumming an endleſs variety of ſuch ſeries, together with ſuch ſeries, as $\frac{n+m}{n.\overline{n+1}.\overline{n+m+1}} + \frac{n+m+1}{\overline{n+1}.\overline{n+2}.\overline{n+m+2}} +$, &c. *ad infinitum*, and innumerable other forms, may eaſily be derived from common geometry and the angular relations of rectilinear figures. But the ſummation of infinite ſeries is a ſubject which it is not my intention to enter into the conſideration of at preſent.

There is a circumſtance attending this conſtruction, which, I dare ſay, never occurred to the marquis. It is this: though on the ſides of a ſquare it brings the re-entering angles to the centre of the circumſcribing circle, and leaves neither interior area nor ſaliant angles; yet, if it be made on the ſides of any given regular polygon, and the re-entering angles be joined by right angles forming a ſimilar polygon, and on them a ſimilar conſtruction be made, and ſo on indefinitely or *ad infinitum*, it will never bring the re-entering angles to the centre of the circle circumſcribing the given polygon, but nearer to it than by any given right line or diſtance. And if ſpirals be ſuppoſed to paſs from the angles of the polygon through the angular points of equal angles in endleſs or indefinite ſucceſſion (each equal to 45 degrees, together with the ſaliant angle of the conſtruction and the complement of its half) formed by the lines of defence taken ſingly from the firſt in the indefinitely ſucceſſive conſtructions, will paſs round the centre of the circle circumſcribing the given polygon an indefinite number of times without ever reaching it; and the area between any two of theſe ſpirals commencing from one of the exterior ſides of the polygon will become nearer in point of equality than by any given ſpace or area to ſuch a part of the polygon, as is expreſſed by the number of its ſides, without ever equalling it. The ſum or aggregate of theſe lines of defence, in decreaſing geometrical progreſſion and endleſs ſucceſſion, can always be expreſſed by a given definite ſtraight line.

From what has been obſerved, the following inferences may certainly be very fairly and impartially drawn reſpecting Montalembert's conſtruction:—1ſt. When the exterior ſides are ſhort, it naturally creates, with a ſection of an ordinary height, dead parts throughout its whole extent. It may perhaps be alleged, that this capital defect can be removed by caſemated defences with artillery near the re-entering angles on a level almoſt with the ditch. To a certain degree it certainly may: but that method of conſtruction, which by itſelf naturally removes every ſuch defect without any ſubſequent or adventitious contrivance, is ſurely entitled to preference in the opinion of every able or intelligent fortifier.

2dly. His ſaliant angles are too ſmall, being leſs in a dodecagon than Vauban's are even in a ſquare; for in a dodecagon his ſaliant angle is only equal to ſixty degrees, whereas in a ſquare Vauban's is equal to 60° 55′ 39″, and in the dodecagon 113° 7′ 48″. This is unqueſtionably an eſſential defect.

3dly. It furniſhes no fire that is direct or perpendicular to the exterior ſides. That this is a great defect cannot be denied.

4thly. Oppoſite to each re-entering angle, at the diſtance only of 90 toiſes from the exterior ſide, there is a quadrangular ſpace (which no fire from the place ſcours, commands, or touches), commencing in an angle of 90 degrees, and terminating in one of 30 degrees, at the ſame diſtance from the exterior ſide with the centre of the dodecagon.

5thly. Oppoſite to every ſaliant angle, and at the diſtance from it only of about 254 toiſes and a half, there is a ſpace that is not ſcoured or commanded by the fire of the place, which commences in an angle of 60 degrees, widens till its breadth becomes equal to the radius of the circle circumſcribing the dodecagon, and then runs on indefinitely at that width between parallel lines.

6thly. The greateſt width of each of the firſt-mentioned ſpaces not traverſed by the fire of the place is to the correſponding width of each of the ſpaces traverſed by it as 104 to 147, nearly: and the greateſt width of each of the laſt-mentioned ſpaces not traverſed by the fire is to the correſponding width of each of the ſpaces traverſed by it as the radius of the circle circumſcribing the dodecagon to 131.769 toiſes, or as 264 to 100, nearly.

7thly. As the reſpective breadths of theſe ſpaces not covered by the fire of the place bear ſo great proportions to the correſponding breadths of thoſe covered by it, and, as the diſtance between every two of them is only equal to one of his lines of defence, or 127.2794 toiſes, the beſiegers may advance almoſt to the very creſt of the glacis without any interruption from the fire of the beſieged. But it is an important object in defence to keep the beſiegers at a diſtance from the body of the place as long as poſſible. For when they once get within the diſtance of ſerious muſketry from it, they will infallibly ſilence artillery, whether the embraſures be open or covered at top, or whether the guns be in caſemates or not.

8thly. The beſiegers may eaſily deſtroy his principal covered muſketry-defences before they are expoſed to his principal caſemated defences with artillery, which being low, to take off the dead parts unavoidably occaſioned by the very nature and badneſs of his conſtruction, are chiefly calculated for defending the paſſage of the ditch, and cannot annoy an enemy till he gets to the very creſt of the glacis, after which every thing almoſt, except battering in breach, is determined without artillery.

Laſtly. The great proportion which the annular area, occupied by his conſtruction, bears to that of the inſcribed circle, will for ever render it unfit for the purpoſe of fortifying any conſiderable town or city.

The marquis de Montalembert's conſtruction has no claim even to originality, if we except the great impropriety (I had almoſt ſaid folly) of making the lines of defence in it form the ſame angle in all figures, and on all occaſions; for when applied to a ſtraight line (as in fig. 1, planche 15, vol. i.) it is the ſame with Mr. Blondel's. In this caſe both give the perpendicular equal to half the exterior ſide, the angle *diminué* equal to 45°, the ſaliant angle of the baſtion equal to 90°, the ſame line of defence, the ſame flanking or re-entering angle, and no curtain. The only difference between them conſiſts in this, that Mr. Blondel, in deſcending from the right line or polygon of an indefinite number of ſides to inferior polygons, makes his angle *diminué* gradually decreaſe according to the rule he has delivered for aſcertaining its magnitude, whereas the marquis keeps his in all figures invariably the ſame. [Mr. Blondel's rule for aſcertaining the angle *diminué* is the following: add fifteen degrees to one-third part of the exceſs of the angle of the polygon above 90 degrees.] Mr. Blondel's conſtruction on an indefinite right line gives the perpendicular nearly double what it ought to be; and the marquis, by keeping this prepoſterouſly large perpendicular in all figures on the ſame exterior ſide and his angle *diminué* invariable, finds the ſaliant angle of his dodecagon equal only to 60°, the ſmalleſt that is generally conſidered by engineers as admiſſible in fortification. This circumſtance, therefore, by the marquis's own acknowledgment, renders his conſtruction inapplicable to any polygon of a ſmaller number of ſides than twelve, and is certainly ſufficient of itſelf to demonſtrate not only its impropriety, but, I believe I may venture to ſay, even abſolute abſurdity. It in fact furniſhes nothing but ſtar-figures with re-entering angles of 90°; and it is manifeſt that no regular figure of this ſort under a dodecagon will give ſaliant angles of 60°.

Notwithſtanding theſe obſervations, which I have certainly made with the ſtricteſt attention to truth, and, I flatter myſelf, alſo to candour, I am heartily diſpoſed to allow every ſort of merit to the marquis's voluminous performance, that either his grace or any other perſon can point out as really belonging to it. I never can be hoſtile to any perſon who even endeavours to enlarge the pomœria either of abſtract ſcience or profeſſional knowledge; for the very attempt is laudable. And I muſt confeſs I am inclined to believe, that ſome of his caſemated contrivances might, in certain ſituations and circumſtances, be advantageouſly united with Vauban's conſtruction. I cannot help conſidering him however as rather a ſuperficial geometer, and as a very looſe and incorrect writer. But to prevent the poſſibility of charging me with miſrepreſentation in regard of his incorrectneſs, I will briefly quote his own words.

In his "Diſcours Préliminaire," p. 38, he ſays, "Le premier ſyſteme de M. de Cohorn eſt abſolument le même que celui du Comte de Pagan, auquel il a ſeulement ajouté une tour caſmatée à chaque orillon, pour défendre les faces hautes des baſtions."

That he ſhould have hazarded ſuch an aſſertion is to me aſtoniſhing. For theſe two methods differ widely and eſſentially. In Coehorn's firſt method, which is applied to a hexagon, for inſtance, the ratio between the perpendicular and exterior ſide is very different from what it is in Count Pagan's; ſince in the firſt the angle formed by the exterior ſide and line of defence is equal to 24° 38′ 48″, whereas in the laſt it is only equal to 18° 26′ 6″. The difference is 6° 12′ 42″. The ſaliant angle of the baſtion in a hexagon by Count Pagan's method is equal to 83° 7′ 48″, whereas in Coehorn's firſt method it is only 70° 42′ 24″, falling ſhort of the other by 12° 35′ 24″. Theſe are capital and eſſential differences. And every perſon who chooſes to examine them will find them very different in many other reſpects. Vauban indeed appears to have borrowed more from Pagan than Coehorn has done. For, in any polygon having its exterior ſide equal to 180 toiſes, their perpendiculars are equal as well as the ſaliant angles of their baſtions; and I am perſuaded that even the greateſt admirers of Vauban can aſſign no good reaſon for his not having followed Count Pagan alſo with regard to the poſition of his flank, and placed it at right angles to the line of defence inſtead of making them meet in an angle of 80° 46′ 57″. There is great reaſon to ſuppoſe that the Count would have made the face of his baſtion conſiderably ſhorter than he did, had he not intended to have three flanks inſtead of one. He makes it 55 toiſes. But it is naturally to be preſumed, that had he intended to conſtruct with a ſingle flank, he would have biſected the perpendicular diſtance between his orillon and inner flank (which is 19 toiſes), and drawn his flank at right angles to the line of defence through this point of biſection, thereby forming a more complete conſtruction for the body of the place with ſingle flanks than Vauban has done. And it is ſomewhat remarkable, that this line nearly coincides with a perpendicular to Vauban's line of defence from its point of interſection with the flank. Had he therefore, inſtead of taking five toiſes from the face of Count Pagan's baſtion, taken ten, and then placed his flank at right angles to the line of defence, he would, without lengthening this line, have given the face of his baſtion its proper length, and at the ſame time made the flank itſelf about equal to the perpendicular, as it ought to be, ſince perpendiculars to the exterior ſides of polygons were firſt introduced into conſtruction for the ſole purpoſe of obtaining flanking defences. Were I at preſent treating formally of fortification, I would deliver a very ſimple method of conſtruction for rendering the flanks always equal to the perpendiculars to the ſides of the polygons. The lengths however aſſigned to theſe perpendiculars are merely arbitrary, and by no means derived from reaſoning either on the properties of the figures or their relative degrees of importance and capability of defence. For there appears no reaſon for giving the ſame perpendicular to a hexagon and every other polygon of a greater number of ſides, as Vauban has done, or to all regular figures above the ſquare, as Count Pagan has done. In like manner Coehorn's perpendiculars are too long, and merely arbitrary: for in his firſt method, which is applied to a hexagon, the angle formed by the exterior ſide and line of defence is, as I have already obſerved, equal to 24° 38′ 48″; in the ſecond, which is applied to a heptagon, 24 degrees and two ſevenths; and in the third, which is applied to an octagon, 25 degrees. This angle in Belidor's firſt and ſecond methods applied to an octagon is alſo too great, being in the former equal to 26° 33′ 54″, and in the latter to 28° 48′ 39″. In his third method however, which is alſo applied to an octagon, it is equal to 21° 48′ 5″, and is not ſo much diſtant from what it really ought to be, as it differs only about three minutes from the angle ſubtended by the true perpendicular of an enneagon.

The perpendiculars are alſo a great deal too long in Blondel's method, which, when it is applied to a ſtraight line or polygon of an indefinite number of ſides, gives one equal to half the exterior ſide.

The marquis, vol. i. p. 193, ſays, "Mais dès que lignes de défenſe peuvent avoir juſqu'à cent cinquante toiſes, et les hypoténuſes environ deux cent dix-huit toiſes, il ſuit que le rayon de ce polygône régulier inſcrit dans le cercle peut être de quatre cent vingt-une toiſes et demie, le rapport du côté du dodecagône à ſon rayon étant comme quinze eſt á vingt-neuf environ, et ce rayon eſt à-peu-près celui d'un polygône à baſtions de quinze côtés, par conſéquent de quinze baſtions."

A right-angled triangle however, having each of the ſides containing the right angle equal to 150 toiſes, does not give the hypothenuſe equal to 218 toiſes, but to 212.132 toiſes, which, as the ſide of a dodecagon, gives the radius of the circumſcribing circle equal to 409.876 toiſes very nearly, and not to 421 and a half, as he ſtates it to be.

In page 203 he falls into the ſame miſtake.—Take however his own words:

"Mais l'on a vu, comme il eſt aiſé de le ſentir, qu'il eſt un terme où le rayon d'un cercle ne pourroit plus déterminer le côté de notre maniere de fortifier: et ce terme eſt celui où la corde de l'angle au centre de trente degrés que le rayon donneroit, paſſeroit deux cent vingt toiſes, puiſqu'alors cette corde priſe pour diagonale auroit deux côtés de plus de cent cinquante toiſes chacun, qui eſt une diſtance plus grande que celle admiſe pour la portée des armes à feu de but en blanc."

Here he mentions 150 toiſes as the greateſt admiſſible length for each of the lines of defence, and 220 for the correſponding hypothenuſe, or exterior ſide, which he calls the diagonal. But the fact is, that a hypothenuſe of 220 toiſes, gives either ſide of an iſoſceles right-angled triangle conſtituted on it greater than 155 toiſes and a half. There are many miſtakes of a ſimilar nature in this gentleman's performance, who appears to have uſed ſcales much more than calculation. The expoſure of error, however, is an unpleaſant taſk, even when the elucidation of truth is the object."

From the whole of what is above delivered, it appears evident, that the magnitude of the angle *diminué*, and of the perpendicular to the exterior ſide, on which the other parts of the conſtruction chiefly depend, is with all the writers on fortification a mere arbitrary aſſumption, for which they do not even attempt to aſſign any reaſon, and much leſs any good one, drawn from the nature of the polygons themſelves, the relative degrees of difficulty in embracing them, or their reſpective degrees of capability of defence. The truth is this, that every polygon has a perpendicular belonging to itſelf, of a preciſe and determinable length, or bearing a given ratio to the exterior ſide. And the aſcertaining of the true perpendiculars belonging to all different polygons is the great deſideratum now wanted for perfecting military conſtruction. We underſtand, that Mr. Glenie, formerly of his majeſty's corps of engineers, has had in his poſſeſſion a complete inveſtigation of this important problem for upwards of twenty-five years. But as he has not yet choſen to make it known to any perſon, we could not expect him to communicate it to us. He has, however, been pleaſed to furniſh us with the following rules, which have been made known to ſeveral individuals, both for regular and irregular conſtruction, on the latter of which nothing of extenſive application or much deſerving of notice has as yet been delivered by the writers on fortification.

A ſhort paper on fortification, delivering a method of conſtruction for always making the flanks either equal to the perpendiculars to the exterior ſides, or in any given ratio to them, and alſo a rule alike applicable to regular and irregular conſtruction; and, in its application to the latter of theſe, infinitely more extenſive than all that has been hitherto publiſhed on the ſubject. By James Glenie, eſq. A. M., and fellow of the Royal Societies of London and Edinburgh.

"After the invention of gun-powder, the ancient method of ſecuring and fortifying places was gradually departed from. Various and important alterations were by degrees introduced into fortification, as the conſtruction and management of artillery became more and more improved. Many treatiſes have been written on the ſubject in different nations and languages. And could we for a moment ſuppoſe improvements in the *ars muniendi* to have kept pace with theſe publications, we muſt naturally conclude, that military conſtruction has by this time reached almoſt all the perfection it is capable of. But although war has been a profeſſion in Europe, and the attack and defence of places has been ſtudied as a ſcience for almoſt theſe two centuries paſt, it is a certain and undeniable fact, that no writer on fortification has as yet either diſcovered or demonſtrated the true lengths of thoſe lines, on which the other parts of the conſtruction of a work chiefly depend; *viz.* the perpendiculars to the ſides of a polygon, from which the body of the place is to be conſtructed. No writers on this ſubject have aſſigned any ſufficient, good, or even plauſible reaſons for the lengths they give to theſe lines. With them all, without a ſingle exception, the perpendiculars to the exterior ſides of a work are mere arbitrary aſſumptions, and not the reſult either of any ſcientific or profeſſional inveſtigation. Even Mr. Muller, in the three new conſtructions which he gives in his “ Elements of Fortification,” in imitation of others, aſſumes thoſe lines in a manner altogether arbitrary, without aſſigning any reaſon whatſoever for ſuch aſſumptions. In page 76 of his ſaid elements, in his problem “ for determining the ſeveral parts of a front of a fortification,” he makes uſe of the following words: “ But as to the length of the perpendicular C D, it is no ways determined; for ſome engineers make it twice as long as others; they ſeem indeed to differ from one another merely out of contradiction; ſince none of them, that I know of, has given any reaſon for this practice.” This obſervation ſufficiently ſhews, in what an imperfect ſtate military conſtruction remains even at preſent. For the true lengths of the perpendiculars form the great deſideratum in it, ſince on them the flanking defences chiefly depend; for the ſole purpoſe of obtaining which, and preventing *dead* parts, the ſides of a polygon are broken, each of them into a curtain with two demi-baſtions to form the reſpective fronts of the work. And it muſt be allowed, that when a work is once adapted to the ground, it is intended to occupy, and its poſition is fixed on, the firſt conſideration after determining the true lengths of the perpendiculars to the exterior ſides, is to conſtruct the whole of it in ſuch a manner, as to have no dead parts; that is, to leave no ſuch parts, as cannot be ſeen, fired on, or flanked from ſome other parts. That this is a leading or fundamental maxim, and ought to be a primary object of attention in the conſtruction of every work, is manifeſt from this circumſtance, that were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the exterior ſides themſelves of a fortification as on the figures, into which they are uſually broken for that purpoſe. The ſtrength of a work, indeed, it muſt be confeſſed, depends chiefly on its flanks, ſince an enemy cannot approach the body of the place, whilſt the flanking defences remain entire. But if there be any dead parts through a deficiency of ſuch defences, the moment an enemy gets to them, he finds himſelf in a ſtate of ſecurity, and out of the reach of the beſieged's fire. The abſolute neceſſity of avoiding them, has always made ſuch a forcible impreſſion on the minds of able fortifiers, as to make them limit the height of ſections. For even when the ſide of a polygon is not more than 180 toiſes, or 360 yards long, and is broken into a curtain with two demi-baſtions, if the ſection of the work be very high, the guns in the flanks cannot *ſee* or ſcour the ditch but at too great a diſtance; and it is well known, that when it is only of an ordinary height, they cannot ſee or command it effectually, nearer than the interſection of the lines of defence. But were it even to be alleged, which would however be an allegation altogether inadmiſſible, that a fortification ought to be conſtructed without the leaſt regard to any flanking defences, and that the avoiding of dead or unſeen parts is an object unworthy of attention, it is evident that the rectilinear is preferable to the zig-zag or angular conſtruction formed by the placing of triangles contiguous to one another, or by the juxta-poſition of angles at the baſes of triangles. For the fire from a ſtraight line is the beſt of the direct kind that can be obtained, being equally and uniformly diſtributed. And the enemy cannot advance againſt it directly, without a good deal of delay, inconvenience, and trouble, but muſt carry on his approaches ſomewhat in the way commonly practiſed, till he gets to the dead parts in front of it, when it will ceaſe to be formidable for want of flanking defences. The angular or zig-zag line, on the other hand, has no good direct fire, and indeed no flanking fire whatever, where it is moſt wanted, or can be of any utility; but a continuity of dead parts, when the ſection is of a ſufficient height, reigns throughout its whole extent. An enemy can approach it without being expoſed to any direct fire from the beſieged, that can annoy him, in the lines biſecting either the ſaliant or re-entering angles, or, in ſhort, in lines directed to any other intermediate points whatſoever, between theſe angles.

And it is no leſs evident, that the direct fire from the circumference of a circle, or from any other curve, that returns into itſelf, is much more equal and uniform, and better diſtributed than that from an angular or zig-zag line.

That able general and fortifier, the celebrated marſhal Vauban, whoſe ſyſtem has been moſt generally followed in Europe, in conſtructing from the ſides of a ſquare, made the perpendicular an eighth part of one of them, in a pentagon a ſeventh part, and in a hexagon, and all polygons of a greater number of ſides, a ſixth part. For this practice, however, he has not aſſigned any reaſons. It is impoſſible indeed to aſſign any good reaſon for giving to a polygon of twenty or thirty ſides, or to a conſtruction on part of a right line, which may be regarded as a polygon of an indefinite or infinite number of ſides, and to a hexagon, or a figure of only ſix ſides, the ſame length of perpendicular. Any perſon, without even a knowledge of geometry, to enable him to draw deductions from the properties of figures themſelves, who reflects but a little on the ſubject, muſt naturally conclude, that there can be no ſound or good reaſon for doing ſo. The truth, in fact, is this, that every polygon has a preciſe and determinate perpendicular of its own, proportional to and connected with its capability of being defended, and of being embraced by a beſieging enemy, as, ſays Mr. Glenie, I ſhall clearly demonſtrate in a ſubſequent paper, that may ere long be preſented to the ſociety, as well as ſhew, how an indefinite number of infinite ſeries may not only be derived from, but alſo ſummed geometrically by means of polygons: and I make no doubt, that had Vauban poſſeſſed a ſufficient knowledge of mathematics for the purpoſe of applying them to the improvement of the theoretical part of his profeſſion, he would have diſcovered the preciſe or genuine lengths of perpendiculars, which different polygons ought to have, and would have regulated his practice accordingly, in the numerous works he conſtructed. Unwilling to give into prolixity, I will not, at preſent, enumerate the different lengths of perpendiculars to the ſides of one and the ſame figure or polygon, which the various writers on fortification have aſſumed, although the enumeration would prove beyond controverſy, that in aſſuming them they were guided by their own whims and fancies, and not by any juſt or determinate rule. It muſt however be regarded as a ſingular fact, that though perpendiculars to the ſides of polygons were firſt introduced into conſtruction, for the ſole purpoſe of obtaining flanking defences, not one of theſe writers, in even treating formally of regular fortification, has either offered, or attempted to deliver, a method of conſtruction for rendering the flanks always equal to the perpendiculars as they ought to be. To ſupply this defect I will now proceed to give ſuch a conſtruction, which, like many other things in ſcience, moſt pregnant with utility, and moſt extenſive in their conſequences, has probably been hitherto overlooked chiefly on account of its ſimplicity.

Conſtruction.

Let A B (*fig.* 17.) be a ſide of any given polygon, either regular or irregular. Let it be biſected in the point C, and let C V be an indefinite perpendicular to A B at the point C. Through the point O let indefinite right lines A S, B T, be drawn from the points A, B, and let C D, C E, be each equal to one-half of AO or BO. Draw the right lines DF, E G, parallel to C V till they meet A S, B T, in the points F, G; and from the ſaid points F, G, draw F K, G L, perpendicular reſpectively to B T, A S. Then I ſay that F K, G L, are each equal to C O.

Demonſtration.

Since by conſtruction A D is equal to B E, and A C to B C, and C O is perpendicular to A B, the angle C A O, or D A F, is equal to the angle C B O or E B G, and D F is equal to E G, being parallel thereto. Wherefore F G is parallel to A B, and equal to D E, which is equal to A O or B O. Conſequently, ſince F K is perpendicular to B T, and G L to A S, by conſtruction, the triangles A C O, G K F, F L G, are equiangular and equal, and C O, F K, G L are equal. Q. E. D.

Thus then the flanks G L, F K, drawn at right angles to the lines of defence A L, B K, or A S, B T, are by this very ſimple conſtruction always equal each of them to the perpendicular C O, whether A B be the ſide of a regular or an irregular polygon.

The perpendicular diſtances F L, G K, of the flanks G L, F K, from the ſhoulders F, G, of the demi-baſtions A F K, B G L, are each of them equal to half the exterior ſide A B. And each of theſe perpendicular diſtances F L, G K, is to the curtain K L, as the ſine of the angle formed by either flank, and ſaid curtain, to the ſine of the angle at the ſhoulder of either demi-baſtion, that is, as the coſine of the angle formed by the exterior ſide, and either line of defence, to the coſine of twice this angle.

From the ſimilarity of the triangles A C O, A D F, B C O, B E G, we have each of the faces A F, B G, of the demi-baſtions equal to $\frac{AO \times AD}{AC}$, or to $\frac{AO \times \overline{AC - \frac{AO}{2}}}{AC}$, or to $\frac{AO \times \overline{2AC - AO}}{2AC}$. Now if A B, or 2 A C, be denoted by 2 P and A O — A C by 2 Q, each of theſe faces will be expreſſed by $\frac{\overline{P + 2Q} \times \overline{P - 2Q}}{2P}$, or by $\frac{P}{2} - \frac{2Q^2}{P}$, which, when the perpendicular C O is but ſmall, is nearly equal to the half of A C, or to a fourth part of the exterior ſide A B.

Each of the angles A F K, B G L, of the ſhoulders of the demi-baſtions is equal to a right angle, together with the angles B A O, A B O, formed by the exterior ſide A B, and the lines of defence.

Scholium.

In like manner may a conſtruction be delivered, which will make each of the flanks F K, G L, have any given ratio $m : n$ whatſoever to the perpendicular C O. For if C D or C E be taken to $\frac{AO}{2}$ as $n : m$, we ſhall have D E equal to $\frac{AO \times m}{n}$, or $n : m$ :: A O : D E (F G) :: C O : G L or F H. And if A C be denoted as above by P and A O by P + 2 Q, each of the faces A F, BG, of the demi-baſtions, will, in this caſe, be equal to $\frac{2n - m}{2n} \times P + \frac{n - m}{n} \times 2Q - \frac{m}{n} \times \frac{2Q^2}{P}$.

Mr. Muller, in the preface to his "Elements of Fortification," expreſſes himſelf in the following words:

"Notwithſtanding the art. - - others."

"For the true art conſiſts in - - weakeſt."

Mr. Muller certainly treats of irregular fortification in a more direct and particular manner than any other author that wrote on the ſubject before him. But his conſtructions on the ſides of an irregular polygon are ſimilar to that which he makes uſe of on the ſides of a regular one. His perpendiculars in both are mere arbitrary aſſumptions, and the flanks, as well as the faces, of his demi-baſtions in each front of both are equal. The rules therefore delivered by him, as well as by the other writers on fortification, may juſtly be regarded as only applicable to regular conſtruction. For although they treat of irregular fortification, they ſuppoſe the perpendiculars to biſect the exterior ſides, the lines of defence, drawn from the extremities of any one of theſe ſides, to make equal angles with it, and the correſpondent parts, ſuch as the faces and flanks ſet off from the ſame, to be equal, alike, and ſimilar. They do not ſo much as even contemplate or once ſpeak of any caſe, wherein the lines of defence make different angles with the exterior ſide, or wherein either the flanks or faces of the ſame front are of different lengths, or unequal to each other. It frequently happens, however, that an engineer cannot preſerve this equality between either the faces or the flanks ſet off from the ſame exterior ſide, without loſing the principal advantages ariſing from the nature and ſituation of the ground, and deviating from what ought to be the leading maxim in the conſtruction of every work, namely, the proportioning of the fire of each part, as nearly as poſſible, to that which the enemy can bring againſt it; or, in other words, the defence in every place to the attack. To remove this difficulty and inconvenience, and to enable engineers to practiſe with facility and expedition the whole poſſible variety of irregular conſtruction, I will proceed to deliver a rule, which I have had in my poſſeſſion for nearly twenty-two years, but have not till now thought proper to communicate to the public. Its ſimplicity has, I ſuppoſe, been the principal cauſe of its being ſo long unnoticed or unattended to. It is eaſily and expeditiouſly carried into practice. It is alike applicable to regular and irregular conſtruction, and in its application to the latter is infinitely more extenſive than all, that has hitherto been publiſhed on the ſubject.

This rule is derived from the following very ſimple geometrical propoſition.

If from the extremities of any given right line, two right lines be drawn in any angles, either equal or unequal, and from any two points in theſe lines, two other right lines be drawn reciprocally meeting them, produced beyond their interſection in any given angle, the angles formed thereby at theſe points, will be equal between themſelves, and each of them equal to the two firſt mentioned angles, together with the given angle.

Demonſtration.

Let AB (*fig.* 18.) be the given right line, from the extremities A and B, of which right lines AF, BE are drawn, making any angles F A B, E B A, therewith whatever, either equal or unequal; and from any two points, C and D, in theſe lines, let other right lines C E, C D reciprocally meeting them, produced beyond their interſection I in angles C E I, D F I, equal each to the given angle. I ſay that the angles

A C E, B D F, formed thereby, are equal, and that each of them is equal to the angle C E I or D F I, together with the angles F A B and E B A.

For (by 32 E. 1.) the angle A C E is equal to the angle C E I, together with the angle C I E: and by the ſame propoſition, the angle C I E is equal to the angle I A B, together with the angle I B A. Therefore A C E is equal to C E I or D F I, together with F A B and E B A.

In like manner, B D F is equal to D F I or C E A, together with F A B and E B A, and conſequently is equal to A C E. Q. E. D.

From the foregoing very ſimple propoſition is derived the following rule.

Whether the angles, which the lines of defence drawn from the extremities of any exterior ſide make therewith, be equal or unequal, and the angle made by another flank with its line of defence be equal, or greater, or leſs than a right angle; in every caſe, the angle of either ſhoulder is equal to theſe three angles taken together; that is, to the angle formed by either flank with its line of defence, together with the two angles formed by the lines of defence with the exterior ſide.

By means of this rule, an engineer may trace out any work, however irregular, in a tenth part of the time requiſite for tracing out even a regular work of the ſame ſize and dimenſions, by the methods of conſtruction hitherto preſcribed and made uſe of. He is under no neceſſity of finding the centre, or of erecting perpendiculars to the exterior ſides, which, in irregular conſtruction, cannot be fixed and aſcertained without calculation, trouble, and inconvenience; but after determining in his own mind on the angles, which the lines of defence are to make with the exterior ſides, and laying them down, fixes the poſitions of the flanks, and ſets them off from the ſhoulders, almoſt as expeditiouſly as he can walk over the ground. He may uſe it in woody places, with nearly as much eaſe and facility as in thoſe that are clear and open; and in every ſituation, in ſhort, where he can ſee to the diſtance of a few yards on each ſide of him. By it he can trace out in the field, and even in the face of an enemy, with almoſt mathematical exactneſs and accuracy, and much more expeditiouſly than by the tentative and inaccurate random-methods commonly made uſe of, and without the aid of a theodolite, plain table, or other bulky or cumberſome mathematical inſtrument: for a pocket Hadley's ſextant, which will be uſeful on moſt occaſions, is all that is neceſſary in any ſituation.

It may not perhaps be improper to mention the circumſtance that firſt led me to think of this rule, and gave riſe to the putting of it in practice. In ſummer, 1783, Colonel Moncrief, Lieutenant Fiddes of the Engineer-corps, and myſelf, went one forenoon to trace out a large pentagonal work, near Stoke's Bay Houſe and Gomer Pond in the Goſport diviſion, on one of the fronts of which it was thought adviſable, from the nature of the ground, to have the flanks of different lengths, and thereby to vary the directions of their fire, and thoſe of the faces of the demi-baſtions, from thoſe which the ordinary method of conſtruction would have given. Colonel Moncrief, who, though he was commonly and juſtly reckoned a good judge of ground and poſitions, was, from the inapplicability of the cuſtomary rules to ſuch a caſe, totally at a loſs for the conſtruction. He had Muller's "Elements of Fortification" in his hands, but could derive no aid or aſſiſtance from them. His embarraſſment, and the novelty of our ſituation, which none of us had thought of beforehand, ſet me a thinking ſeriouſly how we might ſurmount the difficulty. After a few minutes reflection, I diſcovered the foregoing rule, which I immediately applied on the ſpot, and very expeditiouſly. I might, however, as well as others, have overlooked it even to this moment, had it not been for the incident now mentioned. For the ſimpleſt and moſt uſeful things are generally leaſt attended to. I gave copies of it in writing to theſe two gentlemen at their requeſt, and another to his grace of Richmond.

There are various maxims delivered by the writers on fortification, which relate to the conſtruction and defences of the works, independent of the general conſiderations for or againſt the erection of the fortifications themſelves, in different circumſtances and ſituations. Some of theſe maxims, however, are very queſtionable, and, on due examination, would be found to be inadmiſſible, having been laid down by men who did not underſtand the true principles of conſtruction.

The following may, perhaps, be juſtly regarded as the moſt unexceptionable of the maxims that are commonly delivered.

1. There ought to be no part in the whole circuit, or *enceinte*, of a fortreſs or fortification that cannot be ſeen, flanked, or defended from ſome other part. That this is not only an admiſſible but a fundamental maxim, and ought to be a primary object of attention in the conſtruction of every work, is manifeſt from this circumſtance: that, were it not with a view to obtain flanking defences for the different parts, a rampart and parapet might as well be erected on the right lines themſelves, which form the exterior ſides of polygons, as on the figures, into which they are uſually broken for this purpoſe. The ſtrength of a work indeed depends chiefly on its flanks, ſince an enemy cannot approach the body of the place whilſt the flanking defences remain entire. But if there be *dead* or *unſeen* parts, the moment an enemy gets to them he finds himſelf in a ſtate of ſecurity, and out of the reach of the beſieged's fire. An idea, therefore, of the abſolute neceſſity of avoiding them, has always made ſuch a forcible impreſſion on the minds of able fortifiers, as to induce them to limit the height of ſections. For even when the ſide of a polygon is equal to 180 toiſes, or to 360 yards, and is broken into two demi-baſtions and a curtain with flanks, if the ſection of the work be very high, the guns in theſe flanks cannot ſee or ſcour the ditch, but at too great a diſtance. When it is only of an ordinary height, it is well known, that the guns in the flanks do not ſee the ditch effectually nearer than the interſection of the lines of defence, the diſtance of which, in Vauban's conſtruction, from the epaules or ſhoulders, is equal to 45 toiſes nearly. Mr. Blondel's conſtruction, therefore, in polygons of a great number of ſides, and that of the marquis de Montalembert, which is nothing but Mr. Blondel's on a ſtraight line or a polygon of an infinite or indefinite number of ſides, are in this reſpect radically defective, creating dead or unſeen parts throughout their whole extent, which cannot be removed but by caſemates and contrivances, that have no natural connexion whatſoever with the conſtructions themſelves.

2. The defence of every part ought to be always within the certain reach of muſket-ſhot, in order to be defended both by great and ſmall fire-arms: for if any parts be at too great a diſtance from thoſe that flank them, to be within the reach of a ſerious and efficient fire of muſketry, or can be defended by cannon only, the enemy may diſmount theſe cannon by the ſuperiority of his, and thereby deſtroy the defences of ſuch parts at once. But if they be defended

by both cannon and muſketry, ſhould one of theſe two ſpecies of defence be deſtroyed, the other will ſtill remain.

It has been frequently alleged, that a muſket-ſhot will not kill at a greater diſtance than 150 toiſes, or 300 yards, or 900 feet. If this be true, the great line of defence, or the diſtance from the flanked angle or ſaliant angle of the baſtion to the oppoſite flank, ought not to exceed 150 toiſes, or even to be equal to ſo many toiſes. If, on the other hand, the line of defence were to be about two-thirds of that length only, or equal to about 100 toiſes, the baſtions would be too near to one another, and too ſmall, which would both increaſe their number in the ſame circuit or enceinte, and leſſen their ſtrength or capability of defence. The length of the great line of defence, in order to render the fire more certain and efficient, is therefore commonly ſuppoſed to be equal to from 120 to 140 toiſes only.

3. All the defences ſhould be as nearly direct as poſſible: for ſoldiers naturally fire directly before them. The lines of defence, therefore, ſhould be either like Count Pagan's, perpendicular to the flanks, or nearly ſo.

4. A fortification ought to be equally ſtrong on all ſides: for if it be not, an enemy may attack it on the weakeſt, and avail himſelf of its inequality of ſtrength.

To theſe maxims we will take the liberty to add a few others, that are not to be found in the writers on fortification, but which we, nevertheleſs, conceive to be entitled to the moſt ſerious conſideration. They are the following, and we are favoured with them by Mr. Glenie.

1. In regular conſtruction, the two flanks in each front ought to be equal each of them to the perpendicular to the exterior ſide of the polygon, or nearly ſo, ſince perpendiculars to the exterior ſides of polygons were introduced into conſtruction for the expreſs purpoſe of obtaining flanking defences. And in regular conſtruction, when it is neceſſary (as it generally is, in order to make field-works ſuit the ground they occupy) to make the two flanks in the ſame front unequal, their ſum or lengths taken together ſhould be equal to twice the perpendicular diſtance from the interſection of the lines of defence to the exterior ſide, or nearly ſo.

Mr. Glenie, in the foregoing paper, has given a very eaſy method of making the flanks in regular conſtruction, either equal to the perpendiculars, or in given ratios to them.

2. The face of the baſtion, in regular conſtruction, ought never to exceed one-fourth part, or two-eighths of the exterior ſide. The conſtruction, which gives each of the flanks in the ſame front equal to the perpendicular, makes the face of the baſtion equal to a fourth part of the exterior ſide very nearly.

3. The flanked angle, or ſaliant angle of the baſtion, ought never to be leſs than an angle of about $71\frac{1}{2}°$, and ſhould never exceed 120°. In Count Pagan's method, however, and that of Mr. Vauban, who has followed him, this angle in a polygon of only 18 ſides is equal to about 123° 7′ 48″; in one of 30 ſides, to 131° 7′ 48″; and in a conſtruction on a right line, or part of a polygon of an infinite or indefinite number of ſides, to 143° 7′ 48″.

4. The angle of the epaule or ſhoulder ſhould not be leſs than an angle of about $108\frac{1}{2}°$, and ought never to exceed an angle of 150°.

5. The angle of the flank ought not to be leſs than an angle of about $99\frac{1}{2}°$, nor greater than one of about 120°.

6. The outward flanking angle, or the angle formed by the lines of defence at their interſection, ought not to be leſs than 120°, nor ever greater than $161\frac{1}{2}°$.

Laſtly. Different polygons have different perpendiculars, which have reſpectively given ratios to the ſides of the polygons. And the perpendicular that truly belongs to any polygon of a given number of ſides, is different from that which belongs to any other polygon of a different number of ſides; the exterior ſide in each of the polygons being ſuppoſed invariable or the ſame. A conſtruction on the ſides of any polygon of a given number of ſides, ought to be made with the perpendicular that peculiarly belongs to it. An inveſtigation, however, of the various perpendiculars that reſpectively belong to various polygons, from the ſquare up to the right line, which may be regarded as part of a polygon of an indefinite or infinite number of ſides, has never as yet been delivered by any writer on fortification; and it now forms the great deſideratum in military conſtruction.

CONSTRUCTIVE Treason, in *Law*, was defined by 25 Edw. III. cap. 2. See Treason.

CONSUALES Ludi, among the Romans, the ſame with Circenses *ludi*. See alſo Circus.

CONSUALIA, in *Antiquity*, feaſts which were held among the ancients, in honour of the god Conſus, *i. e.* Neptune; different from thoſe other feaſts of the ſame deity called Neptunalia.

They were introduced with a magnificent cavalcade, or proceſſion on horſeback; becauſe Neptune was reputed to have firſt taught men the uſe of horſes; whence his ſurname of 'Ιππιος, *Equeſtris*.

Evander is ſaid to have firſt inſtituted this feaſt: it was re-eſtabliſhed by Romulus, under the name of *Conſus*; becauſe it was ſome god under the denomination of Conſus, that ſuggeſted to him the rape of the Sabines. It is ſaid, that it was with a view to this rape, that he formed this inſtitution. This, however, is certain, that it was to this feaſt all his neighbours were invited; when, taking advantage of the ſolemnities and ſacrifices, he ſeized the women. To draw the greater concourſe of people, he gave out that he had found an altar hid under ground, which he intended to conſecrate, with ſacrifices to the god to whom it had been originally erected.

Thoſe who take upon them to explain the myſteries of the heathen theology, ſay, that the altar hid under ground, is a ſymbol of the ſecret deſign of Romulus to ſeize his neighbours' wives.

The conſualia were of the number of feaſts called *ſacred*; as being conſecrated to a divinity. Originally they were not diſtinguiſhed from thoſe of the Circus: whence it is, that Valerius Maximus ſays, that the rape of the Sabines was effected at the games of the Circus.

Plutarch obſerves, that during the days of this ſolemnity, horſes and aſſes were left at reſt, and were dreſſed up with crowns, &c. on account of its being the feaſt of Neptunus Equeſtris. Feſtus ſays, the cavalcade was performed with mules; it being an opinion, that this was the firſt animal uſed to draw the car.

Servius gives us to underſtand, that the conſualia fell on the thirteenth of Auguſt; Plutarch, in the life of Romulus, places them on the eighteenth, and the old Roman calendar on the twenty-firſt of that month.

CONSUBSTANTIAL, in *Theology*, a term of like import with *co-eſſential*; denoting ſomething of the ſame ſubſtance in kind with another. That this is the meaning of the term ὁμοουσιος has been ſhewn by Petavius, Curcellæus, Cudworth, Le Clerc, Clarke, &c. &c.

The orthodox believe the Son of God to be conſubſtantial with the Father.

The term ὁμοουσιος, *conſubſtantial*, was firſt adopted by the fathers of the council of Nice, convened A. D. 325, and conſiſting of 318 biſhops, to expreſs the orthodox doctrine the more preciſely, and to ſerve as a barrier and precaution againſt the errors and ſubtilties of the Arians; who owned every thing excepting the *conſubſtantiality*.

At the Nicene council, Euſebius propoſed a creed, in which he avoided the word ὁμοουσιος, and anathematized every impious hereſy, without ſpecifying any; but his advice was not followed; ὁμοουσιος was inſerted, and the Arian doctrines were anathematized. Diſputes enſued among the biſhops concerning the meaning and the conſequences of the word ὁμοουσιος. Euſebius aſſented to it, declaring at the ſame time in what ſenſe he underſtood it. His ſenſe of *conſubſtantial* was, that the Son of God was not like created beings, but received his exiſtence and his perfections from the father in a different and in an ineffable manner. Others gave other ſenſes to it; and the debate, ſays Socrates, the eccleſiaſtical hiſtorian, (i. 23. et Soz. ii. 18.) was like a battle fought in the dark. Socrates however was a conſubſtantialiſt, ſo far as even to believe that miracles were wrought by the Monks in favour of that doctrine; though he intimates, that the biſhops of each party diſputed about words of which they had no ideas, and charged one another with conſequences and inferences, which neither ſide would own. By the word ὁμοουσιος the Nicene fathers meant, not the ſame numerical or individual ſubſtance, but the ſame generical ſubſtance or ſubſiſtence. As amongſt men, a ſon is ὁμοουσιος with his father, that is, of the ſame human nature; ſo, in their opinion, the Son of God is ὁμοουσιος with the Father, that is, of the ſame divine nature. By this word, therefore, they intended to expreſs the ſame kind of nature, and ſo far a natural equality. But according to them, the natural equality did not exclude a relative inequality; a majority and minority, founded upon the everlaſting difference between giving and receiving, cauſing and being cauſed. They had no notion of diſtinguiſhing between perſon and being; between an intelligent agent, and an intelligent active ſubſtance, ſubſiſtence, or entity. When they ſaid, that the Father was God, they meant that he was God of himſelf, originally, and underived, Θεὸς αγεννητος, and ὁ Θεος. When they ſaid that the Son was God, they meant that he was God by generation or derivation, Θεοςγεννητος. The unity of God they maintained; and they defended it, firſt, by conſidering the father as the firſt cauſe, the only underived and ſelf-exiſting; ſecondly, by ſuppoſing an intimate, inſeparable, and incomprehenſible union, connection, indwelling, and co-exiſtence, by which the Father was in the Son and the Son in the Father; and thirdly, by ſaying, that in the Father and the Son there was an unity of will, deſign, and conſent, and one divine power and dominion, originally in the Father, and derivatively in the Son. In proceſs of time Chriſtians adopted a notion, that the Son was ταυτοουσιος and μονοουσιος, of the ſame individual ſubſtance with the Father and the Holy Spirit; and they ſeem to have done this with a view of ſecuring the doctrine of the unity.

The Arians declared, that the word was God, as having been made God; but they denied that he was the ſame God, and of the ſame ſubſtance, with the Father; accordingly, they exerted themſelves to the utmoſt to aboliſh the uſe of the word. The emperor Conſtantine uſed all his authority with the biſhops to have it expunged out of the ſymbols; but it ſtill maintained itſelf, and is at this day, as it was then, the diſtinguiſhing criterion between an Athanaſian and an Arian.

Sandius will have it, that the word *conſubſtantial* was unknown till the time of the council of Nice; but it is certain it had been before propoſed to the council of Antioch, held A. D. 270, in which Malchion directed and governed, and in which Paul of Samoſata had been condemned; though it had there the fortune to be rejected. Curcellæus, on the other hand, maintains, that it was an innovation in doctrine in the council of Nice, to admit an expreſſion, the uſe whereof had been aboliſhed by the council of Antioch.

According to St. Athanaſius, the word *conſubſtantial* was only condemned in the council of Antioch, inaſmuch as it implied the idea of a pre-exiſtent matter, prior to the things formed of it; now, in this ſenſe, it is certain, the Father and the Son are not conſubſtantial, there having been no pre-exiſtent matter.

In another council, held at Antioch, A. D. 341, conſiſting of about 100 biſhops, the Arians made a creed and left out the term ὁμοουσιος; but wanting it to be approved by both parties, they called the Son the unchangeable image of the eſſence, counſel, and power of the Father, the firſt born of every creature. The diſputes, however, between the conſubſtantialiſts and the Arians, and alſo the Semi-Arians or ὁμοιουσιοι, *i. e.* the homoiouſians, continued to be carried on with great violence, particularly in the Eaſtern part, for ſeveral years. One remarkable difference has been obſerved between the creeds which were propoſed by the contending parties. The conſubſtantialiſts drew up their creed with a view to exclude and diſtreſs the Arians; whereas the Arians had no deſign to diſtreſs the conſubſtantialiſts, but uſually propoſed creeds to which Athanaſius himſelf might have aſſented; ſo that if the compilers were Arians, their creeds were not Arian. The Semi-Arians agreed with the Arians in rejecting the word ὁμοουσιος, but differed from them in exalting the perfections and dignity of the Son higher than the Arians did, and in affirming that he was ὁμοιουσιος, of *like* ſubſtance and *like* to his father in all things. Dr. Clarke's doctrine, in his "Scripture Doctrine, &c." as ſtated by Le Clerc, (Bibl. Choiſ. xxvi. 419.) ſeems to be the ſame with that of the Nicene council, excepting that he uſes not the word "conſubſtantial." Before the end of the fourth century the conſubſtantialiſts differed and diſputed among themſelves, whether in the Trinity there were three hypoſtaſes, or one hypoſtaſis. See Hypostasis and Trinity.

CONSUBSTANTIATION, a tenet of the Lutheran church, with regard to the doctrine of the real preſence of Chriſt, or the manner of the change made in the bread and wine, in the euchariſt; though the term *conſubſtantiation* was ſubſtituted in the room of tranſubſtantiation, at the cloſe of the thirteenth century, by John, ſurnamed Pungens Aſinus, a doctor of the univerſity of Paris.

The divines of that profeſſion maintain, that, after conſecration, the body and blood of our Saviour are ſubſtantially preſent, together with the ſubſtance of the bread and wine; which is called *conſubſtantiation*, or *impanation*.

This notion, as the biſhop of Meaux juſtly obſerves, has all the diſadvantages, which the Romaniſts, and Sacramentarians, charge on one another, without having a ſingle advantage that can be claimed by either. It has all the abſurdity which the latter charge upon the former, inaſmuch as it repreſents the ſame body exiſting in different places, at the ſame time; and inaſmuch as it repreſents a ſubſtance exiſting without its accidents, or under the accidents of another ſubſtance; but has not the advantage of ſimplicity which the Romiſh doctrine has, in interpreting literally the words, "this is my body." On the Lutheran hypotheſis the expreſſion ought to have been, not "this is my body," but "in, with, and under this is my body." For the Lutherans maintain that the bread remains unchanged, and is that which is ſeen, touched, and taſted; but that the body of Chriſt, the ſame which he had upon the earth and has now in heaven, accompanies the bread. Hence it appears, that the words are to be underſtood neither according to the letter, nor according to any figure of ſpeech ever heard of before. It is neither literally Chriſt's body, nor figuratively the ſign or ſymbol of his body; but it is ſomething with which his body is accompanied. The Lutherans, by maintaining this doctrine of conſubſtantiation, were obliged to adopt another hypotheſis not leſs abſurd, *viz.* the ubiquity, or the omnipreſence, and conſequently the immenſity of the body and human nature of Chriſt; hence they were called *Ubiquitarians.* See alſo IMPANATION, TRANSUBSTANTIATION, and LUTHERANISM.

CONSUEGRA, in *Geography*, a town of Spain in New Caſtile, containing two pariſhes and three convents. It belongs to the knights of Malta; 25 miles S.S.E. from Toledo.

CONSUETUDINIBUS ET SERVITIIS, in *Law*, a writ of right, which lies for the lord againſt the tenant that deforceth his lord of the rent, or ſervice due to him, by cuſtom, or tenure, for his land. This compels a ſpecific payment or performance of the rent or ſervice, and there are alſo others, whereby the lord ſhall recover the land itſelf in lieu of the duty withheld.

CONSUL, the appellation that was given to the firſt, or chief, magiſtrate in the Roman government, vulgarly and commonly called the Roman Commonwealth; though it was compoſed of royalty, ariſtocracy, and democracy, as much as the government of Great Britain is, and was, perhaps, in ſeveral reſpects, the moſt energetic and efficient mixture of theſe three ſimple forms that has ever exiſted in the world, particularly for the purpoſes of conqueſt and ſecurity againſt ſubjugation.

After the deſtruction of royalty at Rome, and the expulſion of Tarquinius Superbus, and his family from thence, in the 244th year of the city, a conſular form of government was eſtabliſhed in the 245th year in its ſtead; the people chooſing to have ſome ſhare in the management of public affairs themſelves; they accordingly choſe two officers, or magiſtrates, annually, who were inveſted with ſovereign authority, and were originally called prætores, *a præeundo*, according to ſome writers, but *a præeſſe* according to others. Theſe were afterwards called conſules, *a conſulendo*, becauſe it was their duty to conſult with the ſenate, with the people, and with each other. From their acting as judges, they were called *judices;* or from their poſſeſſing ſupreme command they were denominated by the Greeks' ΥΠΑΤΟΙ. The firſt conſuls were Brutus and Collatinus. The office of the conſuls laſted a year; and if either of them died in the courſe of the year of their conſulate, a new one was to be elected. In the beginning of the republic the conſuls entered on their office at different times; at firſt, on the 23d or 24th of February, (vii. or vi. Kal. Mart.) the day on which Tarquin was ſaid to have been expelled, which was held as a feſtival, and called "regifugium feſtus;" afterwards on the 1ſt of Auguſt, (Kal. Sext.) which was at that time the beginning of the year, *i. e.* of the conſular, not of the civil year, which always began with January:—in the time of the Decemviri, on the 15th of May, (Id. Maii);—about 50 years after, on the 15th of December, (Id. Decemb.);—then on the 1ſt of July, (Kal. Quint.), which continued till near the beginning of the ſecond Punic war, A. U. 530, when the day came to be the 15th of March, (Id. Mart.);—at laſt, A. U. 598, or 600, it was transferred to the 1ſt of January (in Kal. Jan.), which continued to be the day ever after. After this, the conſuls were uſually elected about the end of July, or the beginning of Auguſt. From their election to the 1ſt of January, when they entered on their office, they were called "conſules deſignati," and whatever they did in public affairs, they were ſaid to do it by their "authority," not by their "power." This interval was made ſo long, that they might have time to acquaint themſelves with the duties of their office, and that inquiry might be made whether they had gained their election by bribery. If, upon trial, they were convicted of that crime, they were deprived of the conſulſhip, and their competitors, who accuſed them, were nominated in their place. They were alſo fined, and declared incapable of bearing any office, or of coming into the ſenate, by the Calpurnian and other laws. (Cic. pro Sylla, 17 and 32. Cic. pro Cornel. Muren. 23, &c. Sall. Cal. 18.) On the 1ſt of January, the ſenate and people waited on the new conſuls at their houſes; from whence, being conducted to the capitol, they offered up their vows, and ſacrificed, each of them, an ox to Jupiter; and then began the exerciſe of their office, by holding the ſenate, conſulting it about the appointment of the Latin holidays, and about other things relating to religion. Within five days they were obliged to ſwear to obſerve the laws, as they had done when elected.

The conſuls were at firſt choſen only from among the Patricians, but afterwards alſo from the Plebeians. L. Sextius was the firſt plebeian conſul, and the ſecond year after him Licinius Stolo; from whom the law, ordaining one of the conſuls to be a plebeian, was called "lex Licinia." Sometimes, but rarely, both conſuls were plebeians; the patricians generally engroſſed this honour. The firſt foreigner who obtained the conſulſhip, was Cornelius Balbus, a native of Cadiz; who became ſo rich, that, at his death, he left to each of the citizens, reſiding at Rome, 25 drachmæ, or denarii, *i. e.* 16s. 1¾d.

The legal age for enjoying the conſulſhip (ætas conſularis,) was 43; and whoever was made conſul at that age, was ſaid to be made in his own year; but we meet with ſome few exceptions from this rule. (ſee AGE.) Before any perſon was made conſul, it was neceſſary for him to have gone through the inferior offices of quæſtor, ædile, and prætor. No one could be created conſul a ſecond time till after an interval of ten years. But theſe regulations were not ſtrictly obſerved.

The inſignia of the conſuls were the ſame with thoſe of the kings, except the crown; namely, the toga prætexta, ſella curulis, the ſceptre, or ivory ſtaff, and 12 lictors, with the faſces and ſecuris. He who had the greater number of ſuffrages was called "Conſul prior," and his name was marked firſt in the kalendar; he alſo had the faſces firſt, and uſually preſided at the election of magiſtrates for the next year. All perſons went out of the way, uncovered their heads, diſmounted from their horſes, and roſe up to the conſuls as they paſſed by them. When a prætor happened to meet a conſul, his lictors always lowered their faſces. Valerius, called Poplicola, took away the ſecuris from the faſces; *i. e.* he took from the conſuls the power of life and death, and only left them the right of ſcourging, at leaſt within the city; for without the city, when inveſted with military command, they ſtill retained the ſecuris, *i. e.* the right of puniſhing capitally. Poplicola likewiſe made a law, granting every one a liberty of appealing, from the conſuls to the people; and that no magiſtrate ſhould be permitted to puniſh a citizen, who thus appealed: a privilege which was alſo enjoyed under the kings. The conſuls originally poſſeſſed kingly powers, both in civil and military matters. But afterwards, when the conſuls came to be much employed from home, or abroad in war, and could not be preſent either to hear or determine civil cauſes, there was an officer conſtituted, under the deſignation of *prætor urbanus*, and frequently called by Cicero *prætor Romanus*, with power to judge matters of law between citizen and citizen. And for the convenience and accommodation, in this reſpect, of the great number of ſtrangers that were always at Rome, another officer was appointed to judge cauſes between them, with the appellation of *prætor peregrinus*. And as provinces came to be added to the Roman ſtate, and the number of cauſes was of courſe greatly increaſed, there were eight prætors appointed, which number continued till the time of Julius Cæſar, who raiſed it to ten.

The conſuls, whilſt they remained in Rome, and before they led out Roman armies into the field, were maſters of all public affairs. For all the other magiſtrates, the tribunes of the people alone excepted, were ſubject to them, and bound to obey their commands. They introduced embaſſadors into the ſenate and gave them audience; and they received all letters from the governors of provinces, and from foreign kings, and ſtates. They alſo propoſed to the ſenate the ſubjects of their debates, and directed all the forms that were obſerved in making their decrees. It was equally a duty likewiſe, belonging to their office, to attend to thoſe affairs that were tranſacted by the people; to ſummon, or call together their general aſſemblies; to report to them, when aſſembled, the reſolutions of the ſenate; and to ratify whatever was determined by the greater number. The laws which they propoſed, and got paſſed, were commonly called by their name. The year was named after them, as it uſed to be at Athens, from one of the archons. The conſuls had alſo command over the provinces, and could, when authoriſed by the ſenate, call perſons from thence to Rome, and puniſh them. (See PROVINCE.) Their authority was ſo great, that kings, and foreign nations, in alliance with the republic, were conſidered to be under their protection. In dangerous conjunctures, the conſuls were armed with abſolute power by the ſenate. In all the preparations that were made for war, as well as in the whole adminiſtration, and management of things in the field, they poſſeſſed an authority almoſt abſolute. For to them it belonged to impoſe on the allies whatever ſervices they judged neceſſary or expedient; to appoint the military tribunes; to enrol the legions, and make the neceſſary levies; and to inflict puniſhments in the field on all that were ſubject to their command. In addition to all this, they had the power to expend whatever ſums they might think convenient, or requiſite, from the public treaſure, and were attended for that expreſs purpoſe by a quæſtor, who was always ready to receive and execute their orders.

When a Roman army encamped, the conſular tent was firſt pitched, and the ground on each ſide of it marked out for it, and on the breaking up of a camp, it was the firſt tent that was permitted to be ſtruck; and one entire company of ſoldiers were always ſtationed round it.

When an action had taken place, in which any of the ſoldiers had ſhewn ſignal proofs of courage, the conſul aſſembled the troops together, and commanded thoſe to approach who had diſtinguiſhed themſelves by any eminent exploit. And after beſtowing on each of them ſeparately, or apart, the commendation that was due to that particular inſtance of their valour, and after recounting likewiſe all their former actions that had ever merited applauſe; he then diſtributed among them the following rewards:—To him who had wounded an enemy a javelin:—To him who had killed an enemy, and ſtripped him of his armour, a goblet, if he were in the infantry; and if in the cavalry, a javelin in ancient times, but afterwards furniture for his horſe. Theſe rewards, however, were not beſtowed on ſoldiers, who, in a general engagement, or in the attack of a city, had wounded or ſpoiled an enemy; but on theſe only, who in ſeparate ſkirmiſhes, and when any occaſion offered, in which, though they were not neceſſarily required to engage in ſingle conteſt, threw themſelves voluntarily into danger, and with deſign, provoked the combat. In taking a city by ſtorm, thoſe who firſt mounted the walls, were honoured by the conſul with a golden crown. And thoſe who ſaved the lives of any of the citizens, or of the allies, by covering them from the enemy in the time of battle, received preſents from the conſul, and were alſo crowned by the perſons whom they had thus preſerved.

Although the conſuls were the diſpenſers of military rewards and puniſhments; although they were entruſted with the abſolute direction of the preparations that were made for war, and exerciſed an uncontrolled authority in the field; although their powers and authorities, when they were preſent in Rome, made ſtrangers ſometimes ſuppoſe the government to be a kind of ſimple royalty; they were in truth, ſo dependent in different reſpects, both on the ſenate and the people, that without their aſſiſtance, they were unable to accompliſh any deſign. Armies require a continual ſupply of neceſſaries. But neither corn, nor habits, nor even the military ſtipends, could at any time be tranſmitted to the legions, without an expreſs order of the ſenate. It was alſo the ſenate that either compelled the conſuls to leave their deſigns imperfect, or enabled them to complete the projects that they had formed, by ſending a ſucceſſor into each of their ſeveral provinces on the expiration of the annual term, or by continuing them in their reſpective commands. The ſenate alſo had the power of either aggrandizing and amplifying the victories that were gained, or of depreciating and debaſing them. It was alſo neceſſary for the conſuls, however far they were removed from Rome, to preſerve the good affections of the people. For though the conſuls might make treaties, the power of annulling, or ratifying, reſted entirely with the people. And what was of ſtill greater moment, the conſuls, on quitting their office, were bound to ſubmit the whole of their paſt adminiſtration to the judgment of the people. On this occaſion they made a ſpeech, and ſwore that they had done nothing againſt the laws.

Conſuls were even continued under the emperors after the republic was deſtroyed; but conſul was here little more than an honourable title; which, however, the people were fond of keeping up; as eſteeming it ſome remains of their ancient liberty. As long as the emperors condeſcended to diſguiſe the ſervitude which they impoſed, the conſuls were ſtill elected by the real or apparent ſuffrage of the ſenate. From the reign of Diocletian, even theſe veſtiges of liberty were aboliſhed, and the ſucceſsful candidates, who were inveſted with the annual honours of the conſulſhip, affected to deplore the humiliating condition of their predeceſſors. In the epiſtles which the emperor addreſſed to the two conſuls elect, it was declared, that they were created by his ſole authority. The title of conſul, however, though the real dignity and ſubſtantial power that accompanied it were loſt, was ſtill the moſt ſplendid object of ambition, the nobleſt reward of virtue and loyalty. The emperors themſelves, even after Conſtantinople became the ſeat of empire, who diſdained the feint ſhadow of the republic, were conſcious that they acquired an additional ſplendour and majeſty as often as they aſſumed the annual honours of the conſular dignity. It dwindled for a long time, and at laſt the ſucceſſion of conſuls finally ceaſed, in the 13th year of Juſtinian, A.D. 541, whoſe deſpotic temper might be gratified by the extinction of a title, which admoniſhed the Romans of their ancient freedom: after him, no emperor either created any conſul, or aſſumed the dignity himſelf. Baſil is the laſt in the conſular liſt, for the year 541. By this time, the dignity was depreciated to that degree, that it was conferred on the meaneſt perſons: indeed, Juſtinian endeavoured to retrieve it 25 years after, and created himſelf conſul, but without effect. Indeed, the annual conſulſhip long lived in the minds of the people; they applauded the gracious condeſcenſion of ſucceſſive princes, by whom it was aſſumed in the firſt year of their reign; accordingly Conſtantine created two conſuls, whoſe office it was to exerciſe ſupreme juriſdictions, the one at Rome, the other at Conſtantinople; and three centuries elapſed, even after the death of Juſtinian, before that obſolete dignity, which had been ſuppreſſed by cuſtom, could be aboliſhed by a law of Leo the philoſopher. Afterwards the title was vilified, as we learn from the emperor himſelf.

From the eſtabliſhment of the republic, and the conſulate under L. Jun. Brutus, and L. Tarq. Collatinus, to the conſulate of Baſil, *i. e.* from the year of Rome 244, or 245, 509 years before Jeſus Chriſt, to the year of Rome 1294, the ſpace of 1049 years, the years were accounted by the conſuls; but from the time of Baſil, in the year of Chriſt 541, we find no mention made of conſuls, or conſulates; but the time was then computed by the years of the emperors' reigns, the indictions, and thoſe of the Chriſtian era.

Indeed, for ſome time after the conſulate of Baſil, the years are marked thus; *poſt conſulatum Baſilii*, 1, 2, 3, &c. (See the Faſti Conſulares of M. D'Almeloveen.) That author reckons 1060 pairs of conſuls, beſides the ſubſtitute conſuls, *ſuffecti*, elected to ſupply vacancies by death; and yet there were but 1049 years, and conſequently only ſo many conſulates.

The perpetual conſulates of the Eaſtern emperors, which compoſe the Faſti Byzantini, commenced in the year of Chriſt 567, and ended in 668, in the laſt year of Conſtans.

Conſtantine Pogonatus would have the conſulate inſeparable from the empire; which it continued to be till the time of Conſtantine Porphyrogenetus.

In this form of government the empire and conſulate were ſo cloſely united, that the empreſs Irene would needs aſſume the conſulate when ſhe was only regent of the empire.

But the French kings, thoſe of Italy, and the Saracen princes who commanded in Spain, taking on them the title of conſuls, as well as emperors of Conſtantinople; theſe laſt deſpiſed it, and laid it aſide; ſo that the name was only continued to the magiſtrates of ſome cities, and certain other officers, as is ſhewn by F. Pagi.

Under the emperors there were *ordinary conſuls*, *honorary conſuls*, and *ſuffecti*; which laſt alſo ſubſiſted in the time of the republic.

In the middle age, we find the word conſul uſed for *comes*, count, and proconſul, for viſcount; as is obſerved by Spelman, and De Marca.

And thus conſul, in our law-*books*, ſignifies an *earl*. Bract. lib. i. cap. 8. tells us, that as *comes* is derived from *comitatu*, ſo *conſul* is derived from *conſulendo*: and in the laws of Edward the Confeſſor, mention is made of *vicecomites*, and *viceconſules*.

Consul, at preſent, is uſed for an officer eſtabliſhed by virtue of a commiſſion from the king, and other princes, in the ports and factories of the Levant, on the coaſts of Africa, Barbary, Spain, and other foreign countries of any conſiderable trade; to facilitate and diſpatch buſineſs, and protect the merchants of the nation.

Theſe commiſſions were never granted to perſons, as conſuls of the French nation, under the age of thirty years. When the conſulate is vacant, the moſt ancient of the deputies of the nation were to diſcharge the function thereof, till the vacancy ſhould be filled up by the king.

The conſuls are to keep up a correſpondence with the miniſters of England reſiding in the courts whereon their conſulates depend. Their buſineſs is, to ſupport the commerce and intereſt of the nation; to diſpoſe of the ſums given, and the preſents made, to the lords and principals of places: to obtain their protection, and prevent the inſults of the natives on the merchants of the nation. There are alſo conſuls of other nations eſtabliſhed in the Levant, eſpecially French and Dutch.

Consuls alſo denote judges elected among the merchants and dealers, in ports and trading towns, chiefly in France; to terminate, *gratis*, and on the ſpot, without any proceſs, ſuch differences and demands as may ariſe relating to their merchandizes, bills of exchange, and other articles of commerce.

The firſt juriſdiction of conſuls eſtabliſhed in France, is that of Tholouſe; the edict of whoſe eſtabliſhment bears date 1549, under the reign of king Henry II.; that of Paris followed fourteen years afterwards. By degrees, they were eſtabliſhed in moſt of the conſiderable trading towns in that kingdom.

Consul, *Chief*, or *Premier Conſul*, the firſt or chief of the magiſtrates, who each of them bore the name of conſul in the late conſtitution of France, which has been ſucceeded by its preſent military deſpotiſm. Napoleon Buonaparte, the preſent emperor of France, was appointed chief conſul, in conſequence of the revolution that took place in 1799.

CONSULAR, of or belonging to a conſul: as for example, a conſular camp, a conſular army, the conſular dignity, the conſular authority, and ſo on.

Consular *comitia*, and *medals*. See the ſubſtantives.

CONSULATE, or Consulship, the office of conſul, which was inſtituted by the Romans, in the year of Rome 245, after they expelled Tarquin the Proud.

CONSULTATION, in *Law*, a writ whereby a cauſe, formerly removed by prohibition from the eccleſiaſtical court to the king's court, is returned thither again.

If the judges of the king's court, upon comparing the libel with the ſuggeſtion of the party, find the ſuggeſtion falſe, or not proved; and therefore the cauſe to be wrongfully called from the court-chriſtian; then, upon ſuch deliberation, or conſultation, they decree it to be returned again, and the writ obtained hereon is called a conſultation.

And, even in ordinary caſes, the writ of prohibition is not abſolutely final and concluſive. For, though the ground be a proper one, in point of *law*, for granting the prohibition, yet, if the *fact* that gave riſe to it be afterwards falſified, the cauſe ſhall be remanded to the prior juriſdiction. If, *e. g.* a cuſtom be pleaded in the ſpiritual court, a prohibition ought to go, becauſe that court has no authority to try it; but, if the fact of ſuch a cuſtom be brought to a competent trial, and be there found falſe, a writ of conſultation will be granted. For this purpoſe the party prohibited may appear to the prohibition, and take a declaration, (which muſt always purſue the ſuggeſtion,) and ſo plead to iſſue upon it; denying the contempt, and traverſing the cuſtom upon which the prohibition was grounded; and if that iſſue be found for the defendant, he ſhall then have a writ of conſultation. The writ of conſultation may alſo be, and is frequently, granted by the court without any action brought; when, after a prohibition iſſued, upon more mature conſideration, the court are of opinion that the matter ſuggeſted is not a good and ſufficient ground to ſtop the proceedings below. Thus careful has the law been, in compelling the inferior courts to do ample and ſpeedy juſtice; in preventing them from tranſgreſſing their due bounds; and in allowing them the undiſturbed cognizance of ſuch cauſes as by right, founded on the uſage of the kingdom or act of parliament, do properly belong to their juriſdiction. Blackſt. Com. vol. iii.

CONSUMMATE ESTATE. See TENANT *by curteſy*.

CONSUMMATION, the end, period, or completion, of any work.—Thus, we ſay, the conſummation of all things: meaning the end of the world. By the incarnation, all the prophecies are to be conſummated.

Conſummation of marriage denotes the laſt act of marriage, which makes its accompliſhment.

CONSUMPTION, in *Medicine*, popularly named a *decline*, is a generic term, occaſionally applied to different diſeaſes, the moſt obvious ſymptoms of which are a gradual decline of the ſtrength and functions of the body, and a diminution of its bulk, in conſequence of the decreaſe or conſumption, as it were, of the fat and muſcular parts. From whatever cauſe, therefore, the nutrition of the body is impeded, conſumption will be the conſequence. The nutrition of the body may be impeded either by ſome great internal diſeaſe, which diſturbs the functions, eſpecially that of digeſtion; or by deficiency of nutriment; or by great evacuations or diſcharges of blood, or fluids ſecreted from the blood. Theſe conſiderations have led noſologiſts to treat of conſumption under three diviſions or genera, with the titles of *Phthiſis*, *Tabes*, and *Atrophia*: the two firſt being produced by internal organic diſeaſes; the laſt by the deficiency, or the abſtraction, or corruption, of nutritious matter.

1. *Phthiſis*, Φθίσις, ſignifying *conſumption* in general, is confined to that ſpecies which originates from diſeaſe of the lungs: this form of conſumption being the moſt frequent and fatal. It is defined "emaciation, with hectic fever, cough, and commonly with purulent expectoration." The emaciation is occaſioned by the diſturbance in the function of digeſtion, which the daily fever produces; by the impediment to the function of reſpiration, which the diſeaſed lungs are unable to carry on; and by the great diſcharges by expectoration, ſweating, or diarrhœa, which latter frequently alternate with each other.

2. *Tabes*, which, in the Latin language, is ſynonymous with *phthiſis* in the Greek, has been arbitrarily reſtricted by noſologiſts to that form of conſumption, which is not accompanied by cough. It is defined, "emaciation, with hectic fever." Any local diſeaſe of long continuance, ſuch as abſceſſes, ulcers, &c. which excites a hectic fever, may become the origin of a *tabes*. But the moſt frequent occurrence of tabes is obſerved in ſcrofulous habits, the ſcrofula being always ſlow in its progreſs: and one of the moſt common varieties of tabes ariſes, where ſcrofula attacks the glands of the meſentery. In this caſe emaciation is produced, not only by the diſturbance of functions, and the ſweats of the hectic fever, but by the phyſical impediment to the nutrition of the body, occaſioned by the morbid condition of the meſenteric glands, through which the chyle cannot paſs, in order to enter the thoracic duct, and thence to be poured into the blood-veſſels.

3. *Atrophia*, derived from the primitive particle α, and τρέφω, *nutrio*, implying *defect of nouriſhment*, has been adopted to denote the ſimple emaciation and loſs of ſtrength, which is not accompanied with hectic fever, nor originates from any organic diſeaſe; but depends altogether on the privation, corruption, or abſtraction, of that which would otherwiſe ſupport the ſtrength of the body. It is defined, "emaciation, without fever." Hence atrophia occurs in thoſe who have ſuffered great evacuations, as from ſalivation, hæmorrhage, ſweat, leucorrhœa, &c.; in thoſe from whom nutriment is abſtracted in undue proportion to their ſtrength and digeſtive powers, as in nurſes ſuckling ſtout children, or continuing them at the breaſt too long; and in thoſe whoſe nutriment is corrupted, as the ſalt proviſions, which excite ſcurvy.

For a view of the nature and requiſite treatment of the different kinds of conſumption, ſee the following articles: TABES *Meſenterica* (or Meſenteric Conſumption), and ATROPHY. Savage's Noſol. Method. Claſs x. ord. 1. Cullen's Synopſis Noſol. Claſs i. ord. 4. and Claſs iii. ord. 1.

CONSUMPTION, *Pulmonary*, the *phthiſis pulmonalis* of medical writers, from φθίω, or φθέω, *corrumpo*, *conſumo*, a diſtreſſing and very fatal diſeaſe, diſtinguiſhed by the occurrence of a frequent cough, with expectoration of puriform matter, hectic fever, emaciation, and debility; to which, in the latter ſtages, colliquative ſweats, often alternating with diarrhœa, ſupervene.

In this diſeaſe the number, degree, and progreſs, of the ſymptoms are extremely various, in different caſes. It uſually commences in an inſidious manner, with a ſlight and ſhort cough, which is often little remarked by thoſe affected with it, but ſoon becomes habitual; or with an occaſional cough, which is more ſevere. At the ſame time, the breathing becomes eaſily hurried by any bodily motion, the patient grows leaner, and becomes languid and indolent. In this ſtate he ſometimes continues for a year, or even for two years, without making any complaint, excepting that he is affected by cold more readily than uſual, which frequently increaſes his cough, and produces catarrh. This, however, is ſometimes relieved, is ſuppoſed to have ariſen from cold alone, and therefore gives no alarm either to the patient or to his friends, nor leads them to take any precaution. But upon ſome occaſion of catching cold, as we commonly ſpeak, the cough becomes more conſiderable; is particularly troubleſome, when the patient lies down at night, and in this ſtate continues longer than is uſual in the caſe of a ſimple catarrh. This may more particularly attract attention, if the increaſe and continuance of cough occur during the ſummer ſeaſon.

The cough, in many inſtances, continues for a long time dry, or without any expectoration; frequently, however, it is accompanied, from the firſt, with an expectoration of a blackiſh or blueiſh mucus, or of tough phlegm; the expectoration being generally moſt conſiderable in the morning, in conſequence of the accumulation of the matter during ſleep. This matter becomes by degrees more copious, more viſcid, and more opake; at length of a yellow or greeniſh colour, and of a purulent appearance, ſometimes ſtreaked with blood. As theſe changes take place, and the cough increaſes, the breathing at the ſame time becomes more difficult, and the emaciation and weakneſs go on alſo increaſing. In the female, as the diſeaſe advances, and ſometimes early in its progreſs, the menſes ceaſe to flow; and this circumſtance, although doubtleſs an effect, the ſex themſelves are generally diſpoſed to believe to be the ſole or principal cauſe of the diſeaſe. During this progreſs ſome pain is commonly felt in the thorax, at firſt under the ſternum, eſpecially, or almoſt ſolely, on the occaſion of coughing: but very often there is a pain in one ſide, ſometimes dull and oppreſſive, ſometimes ſharp and ſhooting, and ſuch as to prevent the perſon from lying eaſy upon that ſide. Even when no pain is felt, it generally happens that phthiſical perſons cannot lie eaſily on one of their ſides, the difficulty of breathing being increaſed, and the cough excited by the attempt.

Theſe ſymptoms have ſeldom continued long, before the pulſe becomes frequent, ſometimes to a conſiderable degree, without much of the other ſymptoms of fever. As it proceeds, the ſkin becomes dry and hot, eſpecially the palms of the hands and ſoles of the feet; a circumſcribed fluſh appears on the cheeks; tranſient chills are often felt by the patient, or he is exceedingly ſenſible to cold; and commonly a regular morning and evening febrile paroxyſm takes place, the evening exacerbation being always the moſt conſiderable, and terminating in ſweats during the night.

The mind is generally little or not at all impaired during the progreſs of pulmonary conſumption; ſometimes it is even more acute than in the previous ſtate of health; and the patient is generally confident of recovery, and his ſpirits buoyed up by hope to the laſt extremity. But the gradual loſs of fleſh and ſtrength, the ſharpneſs of the features, the pearly whiteneſs of the eyes, the incurvation of the nails, and ſometimes the loſs of the hair, but too evidently mark the decay of the bodily functions. At length a colliquative diarrhœa, ſometimes occurring together, but moſt commonly alternating, with the night ſweats, contributes ſtill farther to reduce the patient's ſtrength; and death is frequently preceded by œdema of the feet and legs, and aphthæ in the mouth and throat, and occaſionally by delirium.

Great numbers of people are repeatedly expoſed with impunity to the circumſtances which excite conſumption of the lungs; it is only on a conſtitution of a peculiar nature, prediſpoſed to the diſeaſe, that theſe exciting cauſes operate. This prediſpoſition is frequently hereditary, deſcending from parents whom the diſeaſe had attacked, or who had, at ſome period of their lives, been affected with ſome form of ſcrofula. It is marked by a peculiar inſtability and weakneſs of the vaſcular ſyſtem, more eſpecially of the lungs; inaſmuch as the perſon is ſubject to frequent catarrh, and ſpitting of blood. It is alſo diſtinguiſhed by external peculiarities of form and appearance. Perſons poſſeſſing what has been denominated the ſanguine temperament, namely, having fine ſkin, with large veins, ſoft hair, light eyes, a florid complexion, tall and thin perſon, long ſlender neck, narrow cheſt, and projecting ſhoulders, may be conſidered as having the phthiſical prediſpoſition: and thoſe of the ſanguineo-melancholic temperament, combining with the fine ſkin and complexion, and ſlender form of the former, the dark hair and eyes, and dilated pupils of the melancholic temperament. This combination conſtitutes in general a temperament of peculiar beauty; but in the eyes of the medical phyſiognomiſt, a ſenſe of its delicacy is not the leaſt impreſſion which it excites. Phthiſis ſometimes occurs alſo in perſons who may be ſaid to poſſeſs a ſanguineo-phlegmatic temperament, *i. e.* who have the ſlender form and delicate conſtitution, with an habitually pale complexion, and without the diſpoſition to acute inflammation, which belongs to the ſanguine: it occurs occaſionally too in temperaments almoſt entirely melancholic. See TEMPERAMENT.

In thoſe who have a conſtitutional prediſpoſition to the phthiſical ſtate of the lungs, the diſeaſe is excited by various cauſes of irritation in thoſe organs. Thus it is frequently induced by common inflammation of the lungs, or their membranes, by pleuriſy, peripneumony, catarrh, whooping-cough, aſthma, and the cough connected with meaſles; by frequent over-exertion of the lungs in ſpeaking, ſinging, or blowing muſical inſtruments; by inſpiring certain kinds of duſt or vapour; by hæmoptyſis, or ſpitting of blood; by ſudden variations of the atmoſpheric temperature; by compreſſing the cheſt by tight bandages, &c. Of ſome of theſe cauſes we ſhall ſpeak more particularly.

A great majority of the caſes of pulmonary conſumption is referred, by the ſufferers, to a common cold or catarrh as their origin; the expectoration of mucus, which belongs to catarrh, being gradually changed to an expectoration of pus, and a hectic fever ſupervening. But Dr. Cullen thinks that this ſuppoſition is not eaſily to be admitted; inaſmuch as catarrh is properly an affection of the mucous glands of the trachea and bronchiæ, analogous to coryza, and leſs violent kinds of ſore-throat, which very ſeldom terminate in ſuppuration. He is of opinion, that the apparent catarrh, in ſuch inſtances, was in fact the beginning of phthiſis, for which it may have been miſtaken, as the reſemblance between the two is ſo great as commonly to preclude the means of diſcrimination. This difficulty, however, he admits, preſſes upon us the neceſſity of paying minute attention to every catarrhal cough, eſpecially in thoſe who bear marks of the temperament which is prediſpoſed to conſumption. This obſervation has been inculcated, indeed, from ancient times. "Quod ſi mali plus eſt," ſays Celſus, "et vera phthiſis eſt, *inter initia* protinus occurrere neceſſarium eſt; neque enim facile hic morbus, cum inveteraverit, evincitur." lib. iii. cap. 22. The attention of friends and parents cannot, indeed, be too ſtrongly urged upon this point; to neglect the ſlighteſt catarrhal affection, which continues longer than the uſual ſhort period of a few days, is to neglect the only period of ſuppreſſing a diſeaſe, which almoſt invariably tends to fatality.

Hæmoptyſis, or ſpitting of blood, is enumerated among the cauſes of conſumption, and certainly very frequently precedes it. But this occurrence may, perhaps, be conſidered ſtill more than catarrhal ſymptoms, as a ſign of the commencement, and not a cauſe, of the diſeaſe; more eſpecially when it occurs independently of external violence. Numerous inſtances of hæmoptyſis have occurred, from blows and wounds, in which ulceration did not enſue, or at leaſt was of ſhort duration, and did not materially injure the conſtitution. But when it comes on without any obvious external cauſe, and eſpecially in perſons of one or other of the *temperaments* already deſcribed, ulceration, expectoration of pus, and all the diſtreſſing ſymptoms of phthiſis are generally to be apprehended. In ſuch caſes, there is either a peculiar tenderneſs of the vaſcular ſyſtem in the lungs; or, what is perhaps more generally the fact, an incipient obſtruction, as tubercles, which render the ſmall veſſels liable to give way, when the circulation through them is increaſed by any exertion, or receives an irregular impetus from the action of coughing, occaſioned by cold. In this way catarrh may lay the foundation of phthiſis. Spitting of blood, however, if not among the firſt ſymptoms, very frequently occurs in the courſe of the diſeaſe, eſpecially in the ſtage of purulent expectoration.

When inflammation of the lungs terminates in extenſive ſuppuration, producing one or more collections of purulent matter, termed *vomicæ*, the great irritation often produces hectic fever, which, together with the expectoration of pus, continues after the vomicæ burſt, and the patient is cut off with the ordinary train of ſymptoms belonging to phthiſis.

Perſons who are occupied in various employments, by which the air they breathe is contaminated with various ſubſtances, in the form of a fine powder, are peculiarly liable to be ſeized with phthiſis. Thus hair-dreſſers, bakers, maſons, bricklayers'-labourers, laboratory-men, coal-heavers, and chimney-ſweepers, are frequently ſubject to the moſt obſtinate pulmonic diſeaſes; as are alſo, in an equal degree, the dreſſers of flax and feathers, and the workmen in the warehouſes of leather-ſellers. Many perſons, thus engaged, ſtruggle a long time with a conſtant, hard, troubleſome cough, which at length terminates in conſumption. See Willan on Diſeaſes in London, p. 301.

The exanthematous diſeaſes, ſuch as ſmall-pox and meaſles, the latter of which, more particularly, often lays the foundation of conſumption, ſeem to operate by occaſioning ſome morbid change in the conſtitution, which may be conſidered rather as a prediſpoſition than an actual ſtate of diſeaſe. Dr. Cullen attributes this change to an acrimony left in the fluids by theſe exanthemata, which he believes to be the ſame with the acrimony which prevails in ſcrofula. But if we would avoid hypothetical language, all that can be ſaid is, ſimply, that a prediſpoſition to phthiſis and to ſcrofula is occaſioned by theſe diſeaſes. The meaſles, indeed, may not only induce the prediſpoſition, but, by the irritating cough which it leaves behind, may actually occaſion a conſumption of the lungs.

The venereal diſeaſe, or the irritation of the mercurial medicines neceſſary for its cure, or both combined, appear alſo to excite a prediſpoſition, and lay the foundation of conſumption.

Dr. Cullen has enumerated, among the exciting cauſes of phthiſis pulmonalis, and as the moſt frequent of them all, tubercles in the lungs. In the majority of caſes theſe undoubtedly exiſt; but we muſt conſider them as conſtituting the eſſential part of the diſeaſe itſelf, and, if not originally induced by ſome of the cauſes above enumerated, excited into a ſtate of activity by ſome one of them, perhaps moſt frequently by the common catarrh. Of the pulmonary tubercles, the beſt morbid anatomiſt of the times gives the following account.

There is no morbid appearance, he ſays, ſo common in the lungs as that of tubercles. Theſe conſiſt of rounded, firm, white bodies, interſperſed through their ſubſtance. They are, I believe, formed in the cellular ſtructure, which connects the air-cells of the lungs together, and are not a morbid affection of glands, as has been frequently imagined. There is no glandular ſtructure in the cellular connecting membrane of the lungs; and on the inſide of the branches of the trachea, where there are follicles, tubercles have never been ſeen. They are at firſt very ſmall, being not larger than the heads of very ſmall pins; and in this caſe are frequently accumulated in very ſmall cluſters. The ſmaller tubercles of a cluſter probably grow together, and form one larger tubercle. The moſt ordinary ſize of tubercles is about that of a garden pea; but they are ſubject in this reſpect to much variety. They adhere pretty cloſely to the ſubſtance of the lungs, and have no peculiar covering or capſule, and have little or no vaſcularity. When cut into, they are found to conſiſt of a white ſmooth ſubſtance, having great firmneſs, and often contain in part a thick curdly pus. But when the pus is in conſiderable quantity, it is thinner, and reſembles very much the pus from a common ſore. In cutting into the ſubſtance of the lungs, a number of abſceſſes is ſometimes found, from pretty large tubercles having advanced to a ſtate of ſuppuration. In the interſtices between theſe tubercles, the lungs are frequently of a harder, firmer texture, with the cells in a great meaſure obliterated. The texture of the lungs on many occaſions, however, round the boundaries of an abſceſs, is perfectly natural.

I have ſometimes, Dr. Baillie continues, ſeen a number of ſmall abſceſſes interſperſed through the lungs, each of which was not larger than a pea. The pus in theſe is rather thicker than what ariſes from common inflammation, and reſembles ſcrofulous pus. It is probable that theſe abſceſſes have been produced by a number of ſmall ſcattered tubercles taking on the proceſs of ſuppuration. The lungs immediately ſurrounding theſe abſceſſes are often of a perfectly healthy ſtructure, none of the cells being cloſed up by adheſions. See Baillie's Morbid Anatomy, p. 66, *et ſeq.*

This accurate delineation of the condition of the lungs in the laſt ſtage of conſumption, ſufficiently evinces the impoſſibility of a cure by medicine, and may contribute farther to enforce an attention to its earlieſt ſymptoms.

It muſt not be omitted, however, that although the ſlighteſt ſymptoms of catarrh often prove the commencement of a fatal phthiſis; on the other hand, catarrh does occaſionally put on the appearance of phthiſis, yet terminate well. Dr. Willan obſerves, in his "Reports on the Diſeaſes in London," "many perſons who had catarrhal coughs in March, were farther affected with ſpitting of blood, thick, viſcid expectoration, pains within the cheſt, hectic fever, and diarrhœa, interchanging with night-ſweats, but recovered notwithſtanding in the month of April." He concludes "that ulcerations in the lungs had not been produced, and that the expectorated fluid, ſo alarming in its appearance, was perhaps only compoſed of a puriform ſecretion, and an increaſed diſcharge of mucus, circumſtances uſual under other membranous inflammation." Reports, p. 4 and 147. But it muſt be added, that diſſection has ſhewn, that even this condition of lungs has proved fatal, with the uſual ſymptoms of phthiſis.

To aid in diſtinguiſhing whether the matter expectorated be pus, or mucus only, ſeveral teſts have been propoſed; which, taken together, may afford us the means of an accurate concluſion. 1. The colour; mucus being naturally tranſparent, and pus always opake. When mucus becomes opake, as it ſometimes does, it becomes white, yellow, or greeniſh; but the laſt mentioned colour is hardly ever ſo remarkable in mucus as in pus. 2. The conſiſtence; mucus is more viſcid and coherent, ſo as not readily to be diffuſed in water; pus is more readily friable, being broken into ragged fragments by a little agitation in water. 3. The ſmell; no odour is in general perceived in mucus, but frequently in pus. 4. The ſpecific gravity; it being uſual for the mucus of the lungs to ſwim on the ſurface of water, and for pus to ſink in it; but in this we may be deceived, as pus which has entangled a great deal of air may ſwim, and mucus that is free from air may ſink. 5. The mixture which is diſcernible in the matter brought up; for if a yellow or greeniſh matter appears ſurrounded with a quantity of tranſparent or leſs opake and leſs coloured matter, the more ſtrongly coloured may be generally conſidered as pus. 6. Chemical teſts. Mr. Charles Darwin's experiments ſhewed that the vitriolic acid diſſolves both mucus and pus, but moſt readily the former; that if water be added to ſuch a ſolution of mucus, this is ſeparated, and either ſwims on the ſurface, or, divided into flocculi, is ſuſpended in the liquor; whereas, when water is added to a like ſolution of pus, this falls to the bottom, or by agitation is diffuſed ſo as to exhibit an uniformly turbid liquor. Again he ſhewed, that a ſolution of cauſtic potaſs, after ſome time, diſſolves mucus, and generally pus; and if water be added to ſuch ſolutions, the pus is precipitated, but the mucus not.

With reſpect to the *prognoſis* in conſumption, its tendency in general muſt be conſidered as extremely bad. In conſtitutions, where all the delicacy of the temperaments before deſcribed is obſerved, and more eſpecially if an hereditary prediſpoſition can be traced, the moſt trivial ſymptoms are alarming. The particular degree of danger muſt be eſtimated from theſe circumſtances, from the mode in which the diſeaſe commenced, from its duration, and the ſlowneſs or rapidity of its progreſs, the number and degree of the ſymptoms preſent, and the effects which medicine has already produced. The following aphoriſms, the reſult of Dr. Cullen's obſervation, are worthy of attention.

“ A phthiſis pulmonalis, from hæmoptyſis, is more frequently recovered from, than one from tubercles.

“ A phthiſis from a ſuppuration, in conſequence of pneumonic inflammation, is that which moſt rarely occurs in this climate; and a phthiſis does not always follow ſuch ſuppuration, when the abſceſs formed ſoon breaks, and diſcharges a laudable pus: but, if the abſceſs continue long ſhut up, and, till after a conſiderable degree of hectic has been formed, a phthiſis is then produced, equally dangerous as that from other cauſes.

“ A phthiſis from tubercles has, I think, been recovered: but it is, of all others, the moſt dangerous; and, when ariſing from a hereditary taint, is almoſt certainly fatal.

“ The danger of a phthiſis, from whatever cauſe it may have ariſen, is moſt certainly to be judged of by the degree to which the hectic and its conſequences have arrived. From a certain degree of emaciation, debility, profuſe ſweating, and diarrhœa, no perſon recovers.

“ A mania coming on, has been found to remove all the ſymptoms, and ſometimes has entirely cured the diſeaſe; but, in other caſes, upon the going off of the mania, the phthiſis has recurred, and proved fatal.

“ The pregnancy of women has often retarded the progreſs of a phthiſis, but commonly it is only till after delivery, when the ſymptoms of phthiſis return with violence, and ſoon prove fatal.” Firſt Lines, parag. 898.

Treatment. It will readily appear, from what has been ſaid above, that the cure of pulmonary conſumption muſt be exceedingly difficult; in the latter ſtages, perhaps impoſſible. Many inſtances, however, have occurred, where the attention of the patient to the incipient ſymptoms, and his early adoption and ſteady purſuit of proper meaſures, have averted the fatality of the diſeaſe. When it is deeply rooted, alleviation of the ſufferings is all that can be hoped for.

The treatment of a beginning conſumption will depend much upon the peculiar conſtitution of the patient, as well as on the nature of its origin, and of the ſymptoms which it exhibits; but moſt particularly upon the prevalence of an inflammatory diſpoſition, or of a general debility of the habit; theſe oppoſite ſtates being both accompanied by great irritability; and the principal indications will be to diminiſh the inflammatory action and irritability; and in the latter ſtate, juſt mentioned, to avoid debilitating meaſures, and to ſupport the ſtrength as much as is conſiſtent with the inflammatory irritation that may exiſt.

Where there is conſiderable ſtrength, and a complexion ſtill florid, if there is much pain in the cheſt, or if the pulſe be quick and ſharp, perhaps ſmall bleedings from the arm may be reſorted to, and occaſionally repeated; or blood may be drawn from the cheſt, near the ſeat of the pain, by means of leeches or cupping. But this diſcharge ſhould be always effected after a cautious examination of the circumſtances; for the debility which is apt but too ſpeedily to enſue, may be thus accelerated, and, with it, the worſt ſymptoms of the diſeaſe. It is now well underſtood, that the appearance of the buffy coat on the blood drawn, is by no means alone an evidence of the neceſſity of drawing more; for it will appear in phthiſis, nearly as long as the arteries have power to propel it. The old doctrines reſpecting the buffy coat, have doubtleſs led to much practical error; but no one now conſiders pregnancy a diſeaſe which requires conſtant blood-letting; or uſes the lancet in the hot ſtage of an intermittent fever, although under both theſe circumſtances, the buffy coat is conſtantly found. In conſumption occurring, as it moſt commonly does, in delicate habits, the practice of repeated veneſection decidedly accelerates the fatal courſe of the diſeaſe. Bliſters, on different parts of the cheſt, will better anſwer the purpoſe of relieving a local inflammatory diſpoſition. Iſſues and ſetons have a ſimilar effect, but the conſtant diſcharge tends to debilitate, and the irritation to counteract, in ſome meaſure, the good effects of the evacuation.

During the uſe of bliſters, or other local diſcharge, the internal uſe of medicines, which have been denominated refrigerant, may be alſo reſorted to with ſome advantage; ſuch are acids, eſpecially the vegetable, and certain neutral ſalts, as cryſtals of tartar, nitre, &c. The laſt named ſalt has been ſtrongly recommended by Dr. Dickſon, (ſee Med. Obſ. and Inquiries, vol. iv. p. 208.) eſpecially where there is hæmoptyſis, adminiſtered in ſmall doſes frequently; “ when given early in an hæmoptöe,” he ſays, “ I can almoſt equally depend upon it, as upon the cortex peruvianus in a genuine intermittent.” But general experience does not warrant this encomium to its extent. We believe the digitalis to be the moſt efficacious medicine, in repreſſing that inflammatory action of the arterial ſyſtem at large, and of the pulmonary arteries in particular, which commonly goes on at the commencement of phthiſis, whether accompanied by ſpitting of blood or not. The latter it commonly ſuppreſſes, and we have frequently ſeen a febrile irritation, bordering on hectic, attended with a ſharp and quick pulſe, a dry ringing cough, and commencing emaciation, ſpeedily ſubſide under its adminiſtration. The digitalis may be given in combination with the acids, or with nitre, in a mucilaginous liquid. The ceruſſa acetata, or acetite of lead, was formerly employed in conſiderable doſes, eſpecially by the continental phyſicians, with the view of counteracting inflammatory action, and of ſuppreſſing hæmoptyſis. The medicine, it would appear, is poſſeſſed of ſome efficacy; but the danger of inducing paralyſis, and colica pictonum, and other effects, which reſult from the poiſon of lead, is ſufficient to deter us from its uſe. Where the inflammatory action is high, we ſhould be cautious in employing opiates, with a view to allay the cough; as, in ſuch caſes, opium in any form proves too ſtimulating; but where there is languor and debility, and leſs of the ſanguine temperament, and the cough extremely haraſſing, opiates may be employed with benefit; they will ſave the ſtrength of the patient, by appeaſing the inceſſant irritation of coughing, which tends to wear him down, and deprive him of ſleep.

Medicine, however, will not alone ſecure the patient from the deleterious progreſs of the diſeaſe. He will be required to pay ſtrict attention to his diet, and to every external circumſtance that can influence the functions of the body. His meat and drink, his cloathing, his exerciſe, his ſleep, and even his amuſements, muſt be regulated with a rigid correctneſs, ſo that the whole may combine, with medicine, to accompliſh the ſame object, that of ridding the conſtitution of a diſeaſe of fatal tendency, and reſtoring it to its healthy condition. Diet, regimen, and medicine, muſt become, as it were, the buſineſs of the patient. He muſt regulate his life chiefly upon this principle; that every thing which can heat or irritate the body, or excite any increaſed or irregular action of the arterial ſyſtem, muſt be ſhunned; and every meaſure which can ſupport the conſtitution, without infringing on the laſt-mentioned precept, zealouſly adopted.

The diet of the conſumptive, in the early ſtage, of which we now ſpeak, ſhould be light and nouriſhing, and ſuch as is found to be adapted to his digeſtive powers. Animal food
ſhould

ſhould be avoided; and vegetable matters, in the various forms of preparation, with the ripe ſaccharine and ſub-acid fruits, and milk, be made the excluſive nouriſhment of the patient. Milk is particularly ſerviceable, as being very nutritious, and eaſily digeſtible, without ſtimulating the ſyſtem, and ſhould be conſidered as the baſis of the patient's diet. In ſome habits, however, where the digeſtive powers are feeble, or where there is a peculiar idioſyncraſy, cow's milk is not readily digeſted; a load at the ſtomach, or aceſcency, or head-ach, enſue after it is taken. In ſuch caſes, the whey which is produced by ſeparating the cheeſy part, or the butter-milk which is left after the ſeparation of the oily part, or butter, may be ſubſtituted with advantage. Or the patient may have recourſe to the lighter milk of the goat or the aſs, which contains a ſmaller proportion of thoſe heavy parts. The acidity which milk occaſions in the ſtomach of ſome people, may be occaſionally corrected by the admixture of lime-water. Some of the amylaceous preparations from vegetables, may be uſed in conformity with this plan, ſuch as the arrow-root, tapioca, &c.; and it is ſcarcely neceſſary to add, that with theſe, as with all other food, wine, ſpirits, and fermented liquors, muſt be moſt ſtudiouſly avoided. A mucilaginous vegetable has lately been introduced, which, in feeble habits, ſeems calculated to aſſiſt this plan; namely, the lichen iſlandicus, which may be taken boiled in milk, and which, with its nutritive qualities, combines a very mild tonic power, which ſomewhat aids the digeſtion.

While every thing is done, by means of medicine and diet, to repreſs inflammatory action, while we moderately ſupport the ſtrength, another meaſure, ſtill more efficacious, ſhould be adopted, by thoſe who have the power; they ſhould remove to meet the winter in a warm and more equable climate. Cold, but eſpecially ſudden viciſſitudes of cold and heat, appear to be the moſt inimical circumſtances to a beginning conſumption; and there are many living teſtimonies of the benefits which have been derived from an *early* viſit to a more genial atmoſphere. Portugal, the ſouth of France, and Italy, have been reſorted to, as well as the more regular and moderate climates of Madeira and St. Helena. Where theſe countries cannot be viſited, ſome parts of our own iſland may be tried, as being milder than the reſt; as Devonſhire, and the neighbourhood of Briſtol; which latter place poſſeſſes the additional advantage of a wholeſome tepid water. Inſtances of the inefficacy of all theſe places, are, indeed, but too numerous; but much of this is to be attributed to the patients themſelves. They perſiſt in waiting the reſult of time, or of the leſs efficacious means of relief, until relief is altogether beyond their reach. "It ſeems too often to be the fate of conſumptive patients," ſays Dr. Fothergill, "to do that laſt which they ought to have done firſt; and, by this prepoſterous conduct, ſhorten their own lives, and afflict all who have any regard for them." (Med. Obſ. and Inq. vol. v. p. 369.) The ſame intelligent phyſician affirms, that the Briſtol water is, in his opinion, an efficacious medicine, and that he has "often found it of ſignal benefit to conſumptive patients;" but "it is before the approaches to a confirmed phthiſis that patients ought to repair to Briſtol; otherwiſe, a journey thither will be, not only without benefit, but will be probably detrimental." Ibid. Thoſe who have viſited the pump-room at the hot-wells, muſt have ſeen, with pity, the hopeleſs condition of the poor creatures who are dragged thither, to their perſonal detriment, and the diſcredit of an uſeful medicine.

Exerciſe, by various modes of geſtation, has been frequently employed as a remedy for conſumption. Sydenham, indeed, aſſerted, that riding on horſeback is as effectual in the cure of phthiſis pulmonalis, as the bark in agues, or mercury in the venereal diſeaſe, provided the journeys be long enough. An example is related in Dr. Darwin's "Zoonomia," vol. ii. (the caſe of the late ingenious Dr. Currie of Liverpool) in which an hereditary phthiſis was removed, by perſevering in a daily journey; at firſt in an eaſy carriage, and ſubſequently, as the ſtrength increaſed, alternately in the carriage and on horſeback. Some phyſicians, however, are of opinion, that exerciſe on horſeback is rather pernicious, than otherwiſe, in phthiſis. (See Dr. Dickſon's paper, before quoted.) *Sailing* ſeems to be conſidered at preſent as the moſt efficacious mode of geſtation, eſpecially if a long voyage is taken, which is a double recommendation of the removal to a warmer climate. As a ſort of ſubſtitute for this kind of gentle motion, *ſwinging* has been recommended as a remedy for phthiſis, and Dr. Carmichael Smith has written a treatiſe in its favour. In the uſe of any, or all theſe modes of gentle exerciſe, however, the ſame precept muſt be purſued; they muſt be reſorted to *early* in the diſeaſe.

If the plan, now detailed, has not been adopted in ſuch time and mode, as to have checked the diſeaſe; if it has, therefore, advanced to the confirmed ſtate, with purulent expectoration, hectic fever, and profuſe night ſweats; the principal object of medicine becomes merely palliative, and confined to the alleviation of urgent ſymptoms. If the cough is exceedingly urgent, opiates may be adminiſtered more liberally than in the early ſtage. At this period, ſome of the more ſtimulating expectorants are employed by ſome practitioners, with a view to facilitate the diſcharge of the matter which loads the lungs; ſuch as the oxymel, or other preparation of ſquills, the various balſams, and ſome of the gum-reſins. But the experience of the moſt obſerving phyſicians has decided againſt the utility of theſe heating drugs. (See Dr. Fothergill, loc. cit. Dr. Cullen, loc. cit.) There may be occaſional circumſtances in particular conſtitutions, where the objections may not exiſt, as in a cold phlegmatic habit, or where there is conſiderable debility of circulation, with little inflammatory tendency; but theſe are not common. The colliquative ſweats and diarrhœa frequently alternate with each other, and medicines which relieve the one, are liable to increaſe the other. The diluted ſulphuric acid has a conſiderable influence over the night ſweats, and opium is an efficacious medicine againſt the colliquative diarrhœa. But the opium ſeems to favour the occurrence of the perſpirations, and the acid tends to excite the action of the bowels. Theſe medicines, therefore, muſt be combined, or uſed ſingly and alternately, according to the circumſtances of the caſe. Opium may be alſo given by way of enema, when the diarrhœa is obſtinate.

Some practitioners, preſuming that the hectic fever, and the whole ſeries of phthiſical ſymptoms, were dependent on debility alone, have recommended the uſe of tonic medicines, and a generous diet, in the ſtate of confirmed phthiſis; and ſeveral caſes are on record, in which this plan appears to have been attended with ſucceſs. (See Dr. May's Papers, Lond. Med. Journ. vol. ix. and xi.) But we have already obſerved, ſupported by the authority of Dr. Willan, that catarrhal affections occaſionally put on the ſymptoms of phthiſis, and recover under the ordinary means. There are alſo caſes of this ſort, in which there is, we believe, no ulceration, but only a purulent ſecretion from the membranes, which nevertheleſs terminate fatally, with the worſt ſymptoms of phthiſis; and perhaps it is in ſuch caſes, that a tonic treatment is actually ſucceſsful. But we have no means of diſtinguiſhing theſe caſes from the more general inſtances, in which abundant experience has taught us, that all ſtimulating or corroborant medicines and food tend to augment the cough and expectoration, to increaſe the hectic fever, and therefore to accelerate the deſtruction of the conſtitution, even in the laſt ſtages.

Emetics, repeated daily, have alſo been recommended, as a remedy for phthiſis. They afford, we believe, a temporary relief to the reſpiration and cough, but nothing more. On the contrary, the continued repetition of ſuch an irritation, and ſuch a derangement of the natural action of the ſtomach, neceſſarily tends to debilitate and impair the functions of this viſcus, and to weaken the conſtitution at large.

Before we conclude, we cannot omit mentioning an illuſion, which was foſtered in the minds of ſome enthuſiaſtic phyſicians, after the diſcovery of the compoſition of atmoſpheric air by the chemiſts. It was found that oxygen was the great ſtimulus of life, and the ſource of the ſalutary change of the blood, which is marked by its florid colour. From the general florid colour of the blood of the phthiſical, it was ſuppoſed that conſumption was occaſioned by a general hyper-oxygenation of the ſyſtem; and hence, by an eaſy inference, the breathing of an air, in which the proportion of oxygen was diminiſhed, by the addition of ſome azotic air, ſuch as carbonic acid gas, or carbonated hydrogen, was ſuggeſted as a probable remedy for conſumption. Caſes were even publiſhed, illuſtrative of the extraordinary efficacy of this new medicine. But the light of experience has opened the eyes of the viſionary, and the phantom has diſappeared. It has even been ſhewn by the experiments of the French chemiſts, that the abſorption of oxygen, or, at leaſt, its diſappearance in the lungs, is influenced principally by the ſtate of the body, and not by the proportion exiſting in the air which is inſpired.

Consumption, *meſenteric.* See Tabes *meſenterica.*

Consumption, in *Farriery,* is alſo a diſeaſe incident to horſes, conſiſting in waſte of muſcular fleſh, attended with a ſlow fever. In this diſorder bleeding in ſmall quantities is recommended: mercurial purges, and a powder of native cinnabar, gum guaiacum and nitre, of each one pound, in the quantity of an ounce twice a day; ſpring graſs, and ſalt marſhes, are alſo of great ſervice, when there is any proſpect of a recovery. See Condition.

CONSUS. See Consualia.

CONTA, in *Geography,* a river of Italy in Genoa, which runs into the ſea near Albenga.

CONTACT, (from the Latin *contactus,*) means the meeting, or mutual touching of two things. The word is univerſally uſed in the common affairs of life, as well as in ſcientific ſubjects.

In geometry a line is ſaid to touch another line, or a ſurface, or a ſolid; and a plane figure, or ſurface, is ſaid to touch another ſurface or a ſolid, when the former meets the latter; but, being produced, does not cut it. Thus amongſt the definitions of the third book of Euclid's "Elements of Geometry," a right line is ſaid to touch a circle, when meeting with the ſame, and being produced, it does not cut it. Alſo two circles are ſaid to be in mutual contact when they meet, but do not cut each other. Thus the mathematical meaning of the word contact is clear and definite, nor can any doubt ariſe in the ſpeculative mind concerning the nature of it; the abſtract ideas of a line, of a ſurface, or of a ſolid, being perfect and independent on any phyſical qualities of a doubtful or uncertain nature.

The contact of two ſpherical bodies is only in one point; and the ſame holds of a tangent and the circumference of a circle. See Tangent. Hence, becauſe very few ſurfaces are capable of touching in all points, and the coheſion of bodies is in proportion to their contacts; thoſe bodies will ſtick faſteſt together, which are capable of the greateſt contact. The contact of curve lines or ſurfaces, with either ſtraight or curved ones, is only in points; and yet theſe points have different proportions to one another, as Mr. Robartes has ſhewn in the Philoſ. Tranſ. vol. xxvii. p. 470, or Abr. vol. iv. p. 1.

In mechanics and in philoſophy the contact between two bodies is ſaid to take place, when one body, being brought near another body, cannot be approached nearer to it without, in ſome meaſure, affecting its ſtate, be it of motion or of reſt. Thus a ſtone, being gradually moved towards another ſtone, is ſaid to come in contact with it, when its progreſs is either abſolutely, or partially, obſtructed by that other ſtone. Or, if they be both at reſt, and contiguous to each other, they are ſaid to be in contact, when one ſtone cannot be moved towards the other, without either urging the other forward, or being ſtopped by it, or laſtly without making an impreſſion upon its ſurface. The ſame thing muſt be underſtood of the contact between any two other bodies. But the great queſtion in philoſophy is, to determine whether the bodies which thus hinder, or affect, each other's ſtate of reſt or motion, do actually come in contact with each other's ſurface in the ſtrict mathematical ſenſe, or they exert that hindrance, oppoſition, reſiſtance, &c. in virtue of a repulſive power, which acts at a certain indefinite ſmall diſtance from their ſurfaces. This queſtion ſeems, at firſt ſight, to be eaſily determined; but, when duly conſidered, it will be found to involve certain properties of matter in general, and certain effects, which, in the preſent ſtate of knowledge, are far from being thoroughly underſtood, or ſufficiently examined.—The reaſons which ſuggeſted the above-mentioned doubts, concerning the contact of bodies, and the anſwers which may be offered in elucidation of the ſubject, being fully deſerving of notice, we ſhall now endeavour to ſtate them in a regular and compendious manner.

Sir I. Newton, having placed a glaſs lens of a figure ſlightly convex, upon the flat ſurface of another glaſs, and having preſſed the one againſt the other, obſerved certain coloured rings formed between the two glaſſes, and concentric with the point of contact in the middle of the glaſſes, which point was marked by a colourleſs dark ſpot. He farther obſerved, that thoſe rings of priſmatic colours, and the dark central ſpot, became larger when the glaſſes were preſſed harder againſt each other, and became diminiſhed in ſize when the preſſure was diminiſhed.—From the known figure of the glaſſes employed in this experiment, it is evident that a certain ſpace or a film of air muſt remain between their contiguous ſurfaces; that this ſpace, or film of air, became thinner when the glaſſes were preſſed hard againſt each other, and *vice verſâ;* laſtly, that at the centre, where the glaſſes may be preſumed to have been in real contact, the want of ſpace, or of air, rendered that ſpot colourleſs. In this experiment it is ſuppoſed, that the colours are owing to the ſpace or film of air between the glaſſes; hence the central ſpot exhibits no ſuch colours; and therefore, that when any priſmatic colours appear between the contiguous ſurfaces of two glaſſes, their contact cannot be perfect. Nearly the ſame thing is obſerved when two flat pieces of glaſs are preſſed againſt each other; priſmatic colours being likewiſe ſeen between them, though not in rings, but in rows, which aſſume various directions, according as the preſſure may happen to alter the ſurfaces of the glaſſes. And theſe colours cannot be made to diſappear without the application of an enormous degree of preſſure; hence it is inferred, that, though of two bodies one may ſupport the other, or puſh it forward, yet their contact may not be perfect. Profeſſor Robiſon reckons the force with which two pieces of glaſs muſt be preſſed againſt each other, in order to produce a perfect contact, as equivalent to the preſſure of 1000 pounds for every ſquare inch of ſurface; ſo that if two pieces of glaſs ſtrike againſt each other, without exerting a preſſure equal to 1000 pounds per ſquare inch of ſurface, they may affect each other's motion, and yet not come actually in contact. In conſequence of the above facts and obſervations it is ſuppoſed, that a repulſive power exiſts on the ſurfaces of bodies, and that this power is extended to a very ſmall and inappreciable diſtance beyond the ſurface.

Another argument to prove the exiſtence of the above-mentioned reſiſting power on the ſurfaces of bodies, is derived from the phenomena exhibited in an electrical experiment.—When an electric jar is diſcharged through a metallic chain in a darkened room, ſparks of electric light are viſible between the contiguous ſurfaces of the links. Dr. Prieſtley, conſidering this effect as ariſing from the want of perfect contact between the links, endeavoured to render it perfect by ſtretching the chain, until on making the diſcharge no ſuch ſparks ſhould be ſeen. This he accompliſhed by making one end of the chain faſt on a firm body, and appending weights to the other end. Thus proceeding, he found that a very conſiderable weight was neceſſary to be applied, before the ſparks could be made to diſappear between the links, when the jar was diſcharged through the chain. This induced Dr. Prieſtley to conclude, that the links of the chain could not be brought into actual contact without the application of a great force; ſince the electric ſparks are viſible only when the electric fluid in paſſing through a body or a ſeries of contiguous bodies, meets with ſome obſtruction, or interruption of continuity.

Beſides the exiſtence of the above-mentioned reſiſting or repulſive power on the ſurfaces of ſuch groſs bodies as come under the cognizance of our ſenſes; it is farther ſuppoſed, that each component particle of ſuch bodies is indued with the ſame repulſive power; in conſequence of which they are not actually in contact with each other, though they form the ſame firm and impenetrable compound. And the exiſtence of this power has been inferred from the phenomena of contraction and expanſion. "Whatever opinion," ſays Dr. Young, "we may entertain, with reſpect to the ultimate impenetrability of matter in this ſenſe, it is probable that the particles of matter are abſolutely impenetrable to each other. This impenetrability is not however commonly called into effect, in caſes of apparent contact. If the particles of matter conſtituting water, and ſteam, or any other gas, are of the ſame nature, thoſe of the gas cannot be in perfect contact; and when water is contracted by the effect of cold, or when two fluids have their joint bulk diminiſhed by mixture, as in the caſe of alcohol, or ſulphuric acid, and water, the particles cannot have been in abſolute contact before, although they would have reſiſted with great force any attempt to compreſs them. Metals too, of all kinds, which have been melted, become permanently more denſe when they are hammered and laminated."

Whoever wiſhes to form a proper eſtimate of the merits of the above-mentioned arguments, and of the validity of the propoſition which they are intended to eſtabliſh, muſt neceſſarily take into the account all the other properties of matter, which have been diſcovered and confirmed by repeated and univerſal experience; for, ſhould it appear impracticable to reconcile the former with the latter, then ſuch other explanation of the phenomena ought to be ſubſtituted as may be attended with leſs contradiction and greater ſimplicity.—That there is a mutual and univerſal attraction amongſt all the particles of matter, is now no longer to be doubted; that this attraction is extended to all diſtances under certain determinate laws, has been ſufficiently eſtabliſhed by ſtrict mathematical reaſoning upon the grandeſt phenomena of the world; that the ſurfaces of ſeveral bodies, like thoſe of poliſhed glaſs or metallic bodies, when placed contiguous to each other, manifeſt a conſiderable degree of attraction, is well known; and, laſtly, that the component parts of ſolids cannot be ſeparated without a conſiderable force, is ſhewn by daily and common experience. Yet, notwithſtanding all theſe evidences of attraction between the bodies of the univerſe at all diſtances, we are told that a conſiderable repulſive power exiſts on the ſurfaces of bodies, and even that every individual particle of matter is endowed with a ſimilar power; ſo that in the hardeſt bodies, ſuch as a diamond, a flint, a piece of metal, &c. which cannot be divided without an immenſe force, the component particles are not actually in contact with each other. But let us endeavour to explain the phenomena, upon which the above theory is eſtabliſhed, in a ſimpler and more ſatisfactory manner.

In the experiments with the glaſſes, it is ſaid that their actual contact is prevented by a power of repulſion on their ſurfaces, which cannot be overcome without a very extraordinary preſſure. Would it not be more natural to ſuppoſe, that the contact cannot be eaſily effected on account of the inequalities of the ſurfaces, and of the hardneſs of glaſs? The ſurfaces of the glaſſes may be ſaid to be ſlightly convex or perfectly flat, and ſuch they may appear to be for common purpoſes. But if a perſon examines how thoſe ſurfaces are formed and poliſhed; if he conſiders the alterations of figure which are unavoidably occaſioned by the partial dilatations or contractions ariſing from heat and cold, alſo from the interpoſition of the leaſt particle of duſt, or even of the air itſelf; he will be eaſily perſuaded, that thoſe ſurfaces are by no means really flat or uniformly convex in the ſtrict meaning of thoſe words. It is true that the action of thoſe cauſes, *viz.* the inequalities that are produced by them, are exceedingly ſmall; but it is of ſmall effects that we are ſpeaking. Upon the whole, therefore, it ſeems, that when the flat and convex glaſſes in the Newtonian experiment, or the two flat glaſſes, are placed the one upon the other, they do actually touch each other, but in a few points only, *viz.* with their more prominent parts, and that the other more depreſſed parts of their ſurfaces cannot come into actual contact, unleſs the former are depreſſed to the level of the latter, by the application of an external force; ſo that the application of this force is not required by the exiſtence of a repulſive power, but by the neceſſity of depreſſing the more elevated parts, in order that the lower or hollow parts may come ſufficiently near to each other. This idea ſeems to derive additional confirmation from the degree of preſſure which muſt be applied, &c. being, at leaſt apparently, proportional to the hardneſs of the bodies employed. Thus, in glaſs, which has a great degree of hardneſs and rigidity, a conſiderable preſſure muſt be applied for the purpoſe. Bring two pieces of cold wax cloſe to each other, and the one will puſh the other forward without adhering to it, becauſe in that cold ſtate the contact can take place in a very few points only; but if thoſe pieces of wax be ſoftened by heat, it will be found, that one of them cannot be cauſed to puſh the other without adhering to it, becauſe in that ſoft ſtate their ſurfaces are eaſily adapted to each other, and inſtantly increaſe the number of points of contact.

The appearance of ſparks between the links of a metallic chain, when an electric jar is diſcharged through it, may be explained in a ſimilar manner, without having recourſe to a power of repulſion, &c. for, in conſequence of their figure, and of the inequalities of ſurface, the links cannot touch each other in more than a very few points, through which the electric fluid muſt paſs; and though in thoſe points the contact be perfect, yet the electric fluid either melts them or renders them red-hot, and of courſe affords the appearance of luminous ſparks, in the ſame manner, and for the ſame reaſon, which renders a very fine metallic wire red-hot, or fuſes it, when an electric jar is diſcharged through it; namely, becauſe it is not large enough to afford a free paſſage to the electric fluid. So that if in the ſlender wire, where there is no interruption of continuity, the paſſage of the electric power is rendered manifeſt to our eyes, it may be evidently preſumed that the ſparks may appear between the links of the chain, though thoſe links may be in actual contact. That the light diſappears when, by ſtretching the chain, the points of contact are multiplied, needs no farther explanation. But the circumſtance which contributes to the production of the ſparks, is the adheſion of dirt or duſt, or the partial oxydation of the ſurface of the links; conſidering that chains for electrical purpoſes are generally made of braſs or iron, which are very liable to a ſuperficial oxydation.

With reſpect to the laſt argument, derived from the contraction and dilatation of bodies, we may obſerve, with profeſſor Prevoſt, that the diminution of bulk does by no means prove that the component particles of bodies are not in immediate contact; for a perſon may eaſily conceive an infinite variety of arrangements or diſpoſitions of the elementary particles, which will admit of contraction and dilatation, without the leaſt interruption of contact. Thoſe particles, for inſtance, may be diſpoſed in the form of rings, which, by becoming more extended ovals, or more circular, will occaſion an enlargement, or a contraction of the aggregate. The particles may be ſuppoſed to be arranged in rows, and theſe rows may be diſpoſed at certain angles with each other; ſo that the bulk of the aggregate may become expanded or contracted according as thoſe angles are enlarged or diminiſhed; and ſo forth. That ſome ſuch arrangement is not only probable, but does actually take place in moſt bodies (whence it may be inferred to take place in all bodies) is clearly indicated by the cryſtallization of ſeveral bodies; *viz.* a regular arrangement of their particles; as in zinc, biſmuth, frozen water, ſalts, &c.

CONTACT, *angle of*, is the angle HLM (*Plate* III. *Geometry*, *fig.* 51.) formed by the arc of a circle ML, with the tangent HL, at the point of the contact.

Euclid demonſtrates, that the right line HL, ſtanding perpendicular on the radius CL, touches the circle only in one point: nor can there be any other right line drawn between the tangent and the circle.

Hence, the angle of contact is leſs than any rectilinear one; and the angle of the ſemicircle between the radius CL, and the arc ML, is greater than any rectilinear acute angle.

This ſeeming paradox of Euclid has exerciſed the wits of mathematicians: it was the ſubject of a long controverſy between Peletarius and Clavius; the firſt of whom maintained the angle of contact heterogeneous to a rectilinear one; as a line is heterogeneous to a ſurface: the latter maintained the contrary.

Dr. Wallis has a formal treatiſe on the angle of contact, and of the ſemicircle; where with other great mathematicians, he approves of the opinion of Peletarius. See ANGLE *of Contact*.

CONTAGION, frequently uſed as ſynonymous with *infection*, the matter or medium by which certain diſeaſes are communicated from one individual to another.

Some writers confine the term *contagion*, in conſequence of its derivation from *con* and *tango*, *I touch*, to the communication of thoſe diſeaſes, which can only be transferred by actual contact of the ſick, or of the palpable matter from their bodies; and apply the word *infection* to the communication of thoſe other diſeaſes, which ſpread by means of inviſible effluvia, conveyed through the air, or adhering to articles of clothes, &c., conſtituting what are called *fomites*. The diſtinction is not important, nor is it philoſophically accurate; ſince there is an actual contact of a morbid matter, in all caſes of infection, whether viſible or not; and ſome diſeaſes, as the ſmall pox, are communicated both by palpable matter, and by imperceptible effluvia. Other writers have confined the two terms to more arbitrary ſignifications. We are diſpoſed with Dr. Wilſon and others, to conſider the word contagion as expreſſing the morbid poiſon, or the means of transferring a diſeaſe; and infection, as expreſſing the operation of the poiſon, or the act of communication of the diſeaſe. Treatiſe on Febrile Diſeaſes, vol. i. p. 433.

No mention is made of contagion in the writings of Hippocrates, and it is hence maintained by ſome authors, that the ancients were altogether ignorant of its exiſtence. It cannot be doubted, indeed, that many of the moſt formidable diſeaſes, which are propagated by contagion, in modern times, were altogether unknown to the ancients: ſuch are the ſmall-pox, meaſles, and ſcarlet fever, among the acute; and the venereal diſeaſe, among the chronic contagions. Of the exiſtence of contagion, therefore, the evidence which they poſſeſſed was comparatively ſmall. From the number of the laws in the Moſaic code, however, forbidding all communication with perſons labouring under diſeaſes, which were deemed unclean, and from the caution with which intercourſe with foreign nations was precluded, it would appear that a general notion of that ſpecies of contagion, which infects by actual contact of bodies, prevailed among the Jewiſh people, at a very early period. (See Numbers, chap. xxxi.) And whatever might be the knowledge of profane writers on this point, they were certainly well acquainted with epidemic diſeaſes. But this does not imply a knowledge of the exiſtence of contagion, ſince even with the moſt confirmed proofs of the exiſtence of febrile contagions before them, phyſicians have generally diſputed, in the worſt modern epidemics, whether contagion actually exiſted or not. Livy, however, in deſcribing the progreſs of an endemic fever, expreſsly mentions that contact of the ſick excited the diſeaſe. "Et primo temporis ac loci vitio, et ægri erant, et moriebantur; poſtea curatio ipſa et contactus ægrorum vulgabat morbos." Lib. xxv. cap. 26. But, although it be admitted that the exiſtence of contagion was occaſionally noticed by ancient writers, and was by more modern authors yet more generally known, its nature and mode of propagation were very imperfectly underſtood, until the latter half of the eighteenth century; when the method of induction was applied to the inveſtigation by ſome medical philoſophers, and more particularly by Dr. Haygarth.

Of that ſpecies of contagion by which certain chronic diſeaſes are propagated by actual contact, little need be ſaid. Its exiſtence is obvious in a palpable ſecretion from the morbid part, and therefore the prevention of it, by avoiding contact with the diſeaſed, is clear and eaſy. The diſeaſes in which ſuch contagious matter is produced, are the venereal diſeaſe, the itch, the tinea capitis, or ſcald head, the yaws, ſivvens, &c. The hydrophobia would be incorrectly claſſed with theſe diſeaſes, although it agrees with them in being propagated by contact of a poiſonous ſecretion.

In ſome acute diſeaſes, which may be conſidered as an intermediate claſs, being propagated both by contact and effluvia, there is not leſs evidence of the exiſtence of contagion, as in the ſmall-pox, chicken-pox, and meaſles; becauſe by the conveyance of a portion of the fluid contained in the puſtules of the former, and in the miliary veſicles of the laſt, (See Willan on Cutaneous Diſ. p. 219.) the ſame train of ſymptoms has been excited in the perſons receiving it, as occurred in the perſons by whom the contagious matter was produced. But theſe diſeaſes have been ſtill more frequently obſerved to attack perſons, who have approached within a ſhort diſtance of the ſick, where no contact took place; implying that the contagious matter, in an imperceptible form, was conveyed through the air, from the one body to the other.

The origin of the contagions, which produce theſe two claſſes of diſeaſe, is a ſubject of conſiderable difficulty; and inquiries in regard to it have generally proved fruitleſs, or led the inquirer into abſurdities. By what concurrence of circumſtances, or by what particular idioſyncraſy in any individual, a new animal poiſon can be generated, which ſhall excite a new and formidable diſeaſe, and propagate itſelf, and ſpread fatality for centuries through the world, we are altogether unable to diſcover. Yet in the hiſtory of medicine we find new and unknown contagious diſeaſes ſpringing up, and old ones, which had long prevailed, ſuddenly diſappearing. The ſmall-pox, and the meaſles, were firſt deſcribed by the Arabian phyſicians, and the ſcarlet fever firſt ſhewed itſelf in Italy in the fifth century. (See Willan on Cutaneous Diſ. Order iii. p. 289.) The venereal diſeaſe was alike unknown to the ancients. The Plica Polonica ſeems to have made its appearence only in the laſt century. And on the other hand the leproſy of the Jews, and other ſpecies of leproſy, which raged in Europe in the 12th and 13th centuries, are ſcarcely now to be met with: and we have a remarkable inſtance both of the production and diſappearence of a contagious diſeaſe in the Ephemera Britannica, Sudor Anglicus, or ſweating ſickneſs, as it was termed, deſcribed by Caius and others. In ſuch inſtances, if it ſhould happen at any time that no perſon labours under the diſeaſe, the contagion might be loſt, and the diſeaſe for ever diſappear, unleſs the cauſes, which firſt gave riſe to it, ſhould again concur to reproduce it.

The caſe is altogether different in reſpect to moſt of the fevers of that claſs, which are propagated by effluvia only, and in which no palpable poiſon is generated. Such is the typhus, or fever with debility, which prevails, under different denominations, in the temperate climates. According to the circumſtances of its origin, it has been termed jail-fever, camp, hoſpital, and ſhip-fever: and from the variety of its appearances, putrid, malignant, petechial fever, &c. and it is occaſionally combined with other diſeaſes, along with which it is propagated, as with inflammation of the lungs, conſtituting the peripneumonia typhodes of authors, and with a dyſenteric affection of the bowels, as in the camp-dyſentery. In theſe inſtances the origin of the contagion has been obviouſly traced to circumſtances of common occurrence; hence peſtilential fevers of this claſs frequently ariſe ſpontaneouſly, that is, independently of the propagation of an exiſting poiſon, which has been perpetuated either by fomites or infected perſons from its firſt origin. It is probable that the plague itſelf belongs to this claſs, and is the common fever, rendered peculiarly malignant by climate, ſeaſon, or other circumſtances.

The contagion, by which theſe fevers are propagated, is generated in three ways;—by the confinement of the healthy animal exhalations or effluvia in a crowded, and ill ventilated place;—ſtill more readily by the confinement of morbid effluvia, although the diſeaſe be not originally contagious; and 3dly, by the exhalations from putrifying dead animal matter.

1. Many facts have been recorded, which ſhew that the natural effluvia of the living body, become the ſource of contagious fevers, when accumulated and concentrated in cloſe apartments. Mr. Howel and others, who eſcaped from the black hole of Calcutta, were ſeized with typhus fever. Dr. Lind informs us, that in a frigate, which ſailed from North America, with a healthy crew, a malignant fever broke out before her arrival in England, during very bad weather, which affected a conſiderable number of the men, and of which the ſurgeon's mate, boatſwain, and ſome others died. "Thus," he remarks, "a ſeaſoned ſound crew became infected, as it would appear, from the cloſeneſs or damp below, occaſioned by the hatchway being kept ſhut." (On Fevers and Infections, chap. i. § 2.) Sir John Pringle has obſerved that the hoſpitals of an army, not only when crowded with ſick, but at any time when the air is confined, and eſpecially in hot weather, produce a fever of a particular kind, and often mortal. "I have obſerved the ſame ſort to ariſe," he adds, "in full and crowded barracks, and in tranſport-ſhips when filled beyond a due number, and detained long by contrary winds; or when the men have been long kept at ſea under cloſe hatches in ſtormy weather. Hoſpital-ſhips, for diſtant expeditions, have for this reaſon been generally deſtructive both to the ſick and their attendants. (Obſ. on the Diſ. of the Army, part iii. chap. 7.) But contagious fevers are much more readily produced, under circumſtances of confinement, where uncleanlineſs alſo conſpired: hence ſuch fevers originate moſt frequently among the poor, and even the moſt ſevere peſtilence, when not imported, is generally to be traced to ſome quarter chiefly inhabited by the poor.

2. Where people, labouring under any diſeaſes, are crowded together, more eſpecially if the apartments are imperfectly ventilated, contagion is readily generated. Sir John Pringle remarks, that contagious fever "is incidental to every place, ill aired and kept dirty, that is filled with animal ſteams from foul and diſeaſed bodies; and on this account, jails and military hoſpitals are moſt expoſed to this kind of peſtilential infection; as the firſt are in a conſtant ſtate of impurity, and the latter are ſo much filled with the poiſonous effluvia of ſores, mortifications, dyſenteric and other putrid excrements: nay, there is reaſon to apprehend that when a ſingle perſon is taken ill of any putrid diſeaſe, ſuch as the ſmall-pox, dyſentery, or the like, and lies in a ſmall cloſe apartment, he may fall into this malignant fever." Loc. Citat. It is very common, indeed, to obſerve mild febrile attacks among the poor, which, though originating from cold or other cauſes, become contagious in their courſe, in conſequence of the confined and dirty ſituations in which the patients lie.

3. Contagion occaſionally originates from the putrifying effluvia of animal and vegetable matters. Thus it often happens that typhus fever ſpreads itſelf over the adjacent country, when the dead are left unburied on the field of battle. Foreſtus mentions a contagious fever, which raged at Egmont, in North Holland, occaſioned by the putrefaction of a whale, which had been left on the ſhore. And Senac gives an account of a malignant fever, excited by the offal of a city being accumulated without the walls. It was

received into a ditch filled with water, and, while it was covered with the water, was not attended with any bad conſequence; but when the quantity increaſed, ſo that it roſe above the ſurface, a dreadful fever ſpread through the city, and its neighbourhood; ſo that, where four hundred uſed to die yearly, the deaths were increaſed to two thouſand. Wilſon on Febrile Diſeaſes, loc. cit.

The moſt important part of our inquiry reſpecting contagion, relates to the mode and circumſtances of its communication from individual to individual, and of its general ſpreading, with a view to diſcover the means of ſuppreſſing it, or preventing its extenſion. This inquiry is, of courſe, limited to the contagions which are ſoluble or diffuſible in atmoſpheric air; ſince it is obvious that the indiffuſible contagions may be avoided, by ſhunning the contact of the diſeaſed. And it muſt be premiſed, that all the febrile contagions, whether of a ſpecific origin, as that of ſmall-pox, meaſles, ſcarlet fever, or malignant ſore throat, or ariſing from the caſual change of the animal effluvia, as that of typhus, jail and hoſpital fever, and perhaps the plague, have been found, by experiments, to be propagated according to the ſame laws, and to be ſuppreſſed by ſimilar means.

Whenever a contagious epidemic diſeaſe prevails, a great general alarm is excited, in conſequence of a notion, that the ſeeds of an evil ſo generally deſtructive muſt be diffuſed through the atmoſphere at large; and that, if we ſtir abroad, we breathe contagion at every ſtep. This opinion has been promulgated by phyſicians of high rank and authority; but recent obſervations have ſhewn that it is erroneous: thus at once removing all grounds for this unneceſſary alarm, and directing our attention to thoſe means of precaution and prevention, which can alone effectually contribute to our ſecurity. Dr. Lind long ago affirmed, after an extenſive experience in the great naval hoſpital at Haſlar, that the infection of malignant fever, in common with that of the plague, "extends to no great diſtance from its ſource."—"In the open free air, this infection does not appear to diffuſe itſelf above fifty or ſixty feet from its *nidus.*" Chap. iv. ſect. 2. With reſpect to the plague, it has been well aſcertained by phyſicians, that its contagion does not contaminate the atmoſphere in general, nor indeed to any great diſtance from the ſource of the poiſon. Dr. Patrick Ruſſell, who was in extenſive practice at Aleppo for many years, particularly during the plague of 1760, 1761, and 1762, uſed to adminiſter medicines to great numbers ill of the plague, every day, out of a ſtreet window, about 15 feet above the ground, even in June and July; and, being ſhort-ſighted, he examined the ſores within four feet: yet neither his family, nor any inhabitant of the ſquare where he lived, were infected by the contagion of ſuch a number of peſtilential patients: and he affirms that it never ſpread in a large houſe, if communication were prevented. A numerous body of Franks live in Conſtantinople, and are uniformly preſerved from the plague, by obſerving a few rules of cleanlineſs and *ſeparation,* while the Turks die of it in multitudes around them. De Mærtens, author of a hiſtory of the plague at Moſcow, anno 1771, has ſhewn that the contagion was diſſeminated to a very ſhort diſtance through the air: a fact, which was demonſtrated by the ſucceſsful conduct of the committee of phyſicians, appointed by the empreſs to attend the ſick on that occaſion. The juſt inference from theſe obſervations is, that the plague is principally propagated by actual contact or cloſe communication with the diſeaſed, or their clothes, furniture, &c. "Solo ægrorum et rerum infectarum, contactu communicabatur," ſays Dr. De Mærtens, "atque atmoſphæra contagium non ſpargebat; ſed ſaniſſima ſemper fuit. Viſitando tam prope adſtabamus illis, ut ſola pedis diſtantia inter nos et eos ſæpe vix remaneret, et abſque alia quacunque cautela, quàm quod nec corpus neque veſtes aut lectum tangeremus, a peſte immunes permanſerimus. Linguam propius obſervando ſolebam linteum aceto communi imbutum naribus et ori admovere." Hiſt. Peſt. Moſcueus.

In addition to ſuch facts, which are ſtated by phyſicians of high reſpectability, we have the ſupport of direct experiments, made reſpecting a contagion not leſs virulent and fatal than the plague itſelf, *viz.* that of the ſmall-pox; by which the ſhort diſtance, to which the poiſon is communicated through the air, is demonſtrably proved.

Dr. O'Ryan, profeſſor of phyſic in the college at Lyons, inſtituted the following experiments, which we ſhall relate in the words of Dr. Haygarth's tranſlation: "I placed a large doſſil of cotton, ſoaked in variolous matter, on the middle of an oval table, whoſe leaſt diameter was three feet. I ſeated ſix children around it, three on each ſide of the table, in ſuch a manner that all were ſituated within half a yard of the infectious cotton. This experiment was ſometimes made in the open air, ſometimes in the houſe. I took care to renew, every ſecond day, both the variolous matter, and the ſubſtance which contained it. I alternately uſed the poiſon taken from the inoculated and from the caſual ſmall-pox; and I copiouſly impregnated with it balls of cotton, wool, and ſilk. This operation, repeated during a whole week, morning, noon, and night, for an hour at each ſitting, produced no effect.

"I then ſent away the children, deſiring the parents to acquaint me, in caſe any indiſpoſition appeared, and to bring them to me a fortnight afterwards, although no alteration ſhould have taken place in their health. I declare that not only for that term, but for many ſucceeding months, during which I took care frequently to viſit them, they all enjoyed perfect health. It was not till nine months after this time, that four of theſe children had a mild kind of ſmall-pox.

"Having concluded from theſe experiments, that the children could not have eſcaped infection; but becauſe the variolous matter might have loſt that ſpring and that degree of energy, which perhaps it may poſſeſs on ariſing immediately from the human body, I placed a perſon, in the eruptive fever of the ſmall-pox by inoculation, at the diſtance of about half a yard from four children properly prepared: each expoſure continued one hour, and was repeated daily for a fortnight, reckoning from the commencement of the fever till the puſtules were become perfectly dry. Not one of the four received the infection. Two months afterwards, I inoculated three of theſe children: they had the diſtemper in a very mild manner, and recovered without difficulty." Diſſ. ſur les Fievres Infectieuſes et Contagieuſes. See Dr. Haygarth's Sketch of a Plan to exterminate Small Pox, vol. i. p. 79.

Again, proofs that the ſphere of activity of febrile contagion is extremely limited in the air, have been greatly multiplied ſince the inſtitution of fever-wards and houſes of recovery, which were ſuggeſted by Dr. Haygarth, from the contemplation of ſuch facts as we have juſt detailed. The fever-wards, in the Cheſter Infirmary, are ſituated within thirteen yards of ſome other wards of the building; yet, during a ſpace of above twelve years, the contagion of fever was never known to extend itſelf from thence. And Dr. Currie relates, in a letter to Dr. Clark of Newcaſtle, that contagious fever had not, during ten years, extended itſelf, in any one inſtance, from the fever-wards, either in the Liverpool Infirmary or in the workhouſe, although the latter of theſe buildings has ſometimes contained 1,400 perſons.

In like manner, the houſe of recovery, in Gray's Inn Lane, London, which ſtands in a row, in contact with dwelling houſes on both ſides, and which has had a conſtant ſucceſſion of contagious fevers in its wards, has now (Dec. 1807) been open nearly ſix years, and no fever has occurred in its neighbourhood during the whole period. Nay, it has been farther aſcertained, in theſe wards and houſes, as well as in the habitations of the rich, that, in a clean well-aired room of a moderate ſize, the contagious poiſon is ſo completely diſarmed of its virulence, by dilution with freſh air, as rarely to excite the diſtemper, even in nurſes, expoſed to all the putrid miaſms of the breath, perſpiration, and other diſcharges. See Dr. Haygarth's Letter to Dr. Percival, on the Prevention of Infectious Fevers, 1801. Dr. Clark's Collection of Papers reſpecting Fever-wards, Newcaſtle, 1802. Reports of the Inſtitutions for the Suppreſſion of Contagious Fever, in Dublin, London, Mancheſter, &c.

A ſufficient number of facts, we truſt, has been cited, to ſhew that the popular opinion and apprehenſion are groundleſs, and that the moſt malignant contagions are never conveyed to any great diſtance through the atmoſphere; but that they are, in fact, rendered inert and harmleſs, by diffuſion in the open air, and even in the air of a well ventilated apartment. The neceſſary inference is, that all peſtilence is propagated by *near approach* to, or *actual contact* of, the diſeaſed, or by the *conveyance of the contagious poiſon in articles impregnated with it*.

Dr. Lind remarks, in the eſſay before quoted, "by a fixed attention to this ſubject for ſome years paſt, I am convinced, that the *body* of the diſeaſed, kept exactly neat and clean, is not ſo liable to impreſs the *taint*, as his late wearing apparel, dirty linen, and uncleanlineſs of any ſort about him, long retained in that impure ſtate:—I ſay, theſe laſt contain a more certain, a more concentrated, and contagious poiſon, than the newly emitted *effluvia* or excretions from the ſick." There is no doubt that ſuch *fomites* ſpread and perpetuate many contagious diſeaſes among us. It is aſcertained that cotton, hair, and wool, are the ſubſtances moſt readily imbued with contagion, which becomes more virulent, when the air is prevented from having free acceſs to them. If infected clothing, made of theſe materials, remain for ſome weeks in a full cloſe room, or locked up in cheſts, and be then ſold out during an unhealthy ſeaſon, not only the wearers of it, but all who have intercourſe with them, are preſently affected, and contribute to ſpread the diſeaſe. Thus the Europeans, ſays Dr. Lind, have carried the ſmall-pox to almoſt all parts of the world, where their ſhips have opened a trade; though the ſeamen in thoſe ſhips might not have been afflicted with it in their voyage. This poiſon has been conveyed, in an old blanket, to nations of Indians, ſome of whom it has almoſt extirpated. In the year 1746, while the French ſquadron, under the command of the duc D'Anville, paſſed the ſummer at Chebucto, now Halifax, an infectious fever prevailed among them, and cut off a great number of their men. On the return of the ſquadron to Europe, ſeveral blankets and old clothes, which had been uſed in their tents and hoſpitals, were unfortunately left behind. Theſe fatal receptacles of diſeaſe were ſoon after eagerly picked up by a party of Mimack Indians, who accidentally came to viſit the place, and who clothed themſelves with ſome of them; others they carried home, and diſtributed among their tribe. The unhappy conſequence of which was the almoſt total extinction of the Mimack nation; ſcarce any of them ſurvived. The Engliſh, upon traverſing the country next ſummer from Annapolis Royal, were ſurpriſed with finding the dead bodies and ſkeletons of whole families lying unburied in their huts, until the neutrals, who alſo inhabited that country, and the neighbouring Indians informed them, that the Mimacks had been cut off by the French blankets. In ſeveral of their huts, theſe blankets were found, where not one of the family remained. (Lind. chap. iv. ſect. 2.)

Dr. Willan remarks, on the ſubject of fomites, that the houſes of the poor in London are often ſo little taken care of, that in the apartments where contagious fevers have exiſted, enough of the contagion remains, to infect all the inmates who ſucceſſively occupy the ſame premiſes; and he mentions ſome particular houſes, in which the fomites of fever were thus preſerved for a ſeries of years. (Reports on Diſ. of London, p. 256.) The ſame accurate obſerver ſtates, that the ſcarlet fever, which, when epidemic, has often commenced in the eaſtern extremity of London, and ſpread weſtward, though it may have been ſometimes imported with infected goods brought from abroad, will be more frequently found to have originated from the large repoſitories of old clothes, near the Tower, Eaſt Smithfield, and Ratcliffe Highway. "During the laſt year of my attendance at the Public Diſpenſary," Dr. Willan adds, "I had reaſon to think that a family in Wild-ſtreet, Lincoln's-inn-fields, was infected with ſcarlatina maligna by clothes bought in Monmouth-ſtreet. More than fifty perſons in the adjoining houſes were ſoon affected with the diſeaſe, which afterwards traverſed Drury-lane, and ſpread by Long Acre, and the ſtreets connected with it, through ſeveral pariſhes in Weſtminſter." (On Cutan. Diſeaſes, p. 391.) Thus alſo, and not by the impregnation of the atmoſphere, the ſmall-pox, meaſles, typhus, whooping-cough, itch, tinea capitis, &c. are perpetuated among us; and the febrile contagions are from time to time widely diffuſed.

A great number of facts are on record, which ſerve to ſhew the extreme virulency of contagious poiſons, which have been pent up and accumulated in cloſe places, and have contaminated articles of clothing under ſuch circumſtances. In thoſe periods of our hiſtory, when a leſs enlightened humanity was careleſs of the health of criminals, and priſoners in general, the occurrence of what were called *black aſſizes* was frequent in different parts of the country. The criminals, brought out of filthy and infected cells, with their clothes fully imbued with *fomites*, often ſpread a mortal contagion through the court, aſſembled for the purpoſes of juſtice. "The moſt pernicious infection next to the plague," ſays lord Bacon, "is the ſmell of the jail, where the priſoners have been long, and cloſe, and naſtily kept, whereof we had in our time experience, twice or thrice, when both the judges, who ſat upon the jail, and numbers of thoſe who attended the buſineſs, ſickened upon it and died." One of the inſtances, to which lord Bacon alludes, was doubtleſs at the fatal aſſizes, held at Oxford, in the year 1577; of which Stow gives the following account in his Chronicle. "On the 4th, 5th, and 6th days of July, were the aſſizes held at Oxon, where was arrainged and condemned Rowland Jenkins for a ſeditious tongue; at which time, there aroſe amidſt the people ſuch a damp," (an expreſſion in the language of thoſe days, ſignifying bad air) "that almoſt all were ſmothered, very few eſcaped that were not taken, here died in Oxon 300 perſons, and ſickened there, but died in other places, 200 and odd." Similar infections took place at the black aſſizes at Taunton, and alſo at thoſe of Exeter, in 1586; at which laſt ſome Portugueſe ſailors ſpread the contagion, having been confined, without change of clothes, "in a deep pit and ſtinking dungeon." The laſt black aſſizes at the Old Bailey were held ſo late as the year 1750. On the 11th of May the priſoners, who were brought into court, ſome of them labouring under jail-fever, had been kept nearly a whole day in ſmall, cloſe, and crowded apartments. All the individuals, who were ſeated in the courſe of a draught of air, paſſing from the priſoners to an open window, were ſeized with the diſtemper: the reſt eſcaped. The lord mayor and thoſe of the bench who ſat on his left hand were infected; while the lord chief juſtice, and the recorder, who ſat on his right, eſcaped. Many of the Middleſex jury, on the left ſide of the court, died of it, while the London jury, who ſat oppoſite to them, received no injury. On the 13th of May died alderman Lambert; on the 14th R. Cox, under-ſheriff; on the 17th baron Clark; on the 19th ſir T. Abney, juſtice of Common Pleas; T. Otway, barriſter; W. Baird, ditto; W. Sharplop, and four others; on the 20th, the mayor and eight of the Middleſex jury. See Gentleman's Magazine.

Theſe facts, while they evince the active virulence of contagion, accumulated in fomites in unventilated and crowded rooms, afford, at the ſame time, evidence, that, except where it is carried at once by a direct draught of air, its tendency to diffuſe itſelf, and its power when diffuſed, through the atmoſphere in general, is very limited. It is only under ſuch circumſtances of concentration, that the virulence of contagion is ever ſo great, as to be infectious at more than a few feet diſtance. It has already been ſhewn, that when ariſing from the *body* of the ſick, either in the open air, or in well ventilated rooms, its influence is confined to a very ſmall diſtance.

Before we point out the means of prevention from contagious diſeaſes, which theſe facts and obſervations ſuggeſt, it will be neceſſary to attend more particularly to the circumſtances of individual infection.

All individuals are not equally liable to be infected by contagion; and ſome, though the number is extremely ſmall, eſcape altogether. Thus, there are perſons who have gone through a long life without taking the ſmall-pox. The conſtitution, however, appears occaſionally to undergo ſuch a change, in the courſe of life, that thoſe who, in earlier years, had reſiſted the action of this contagion, have received it on ſome future expoſure to its influence. There is a conſiderable difference, too, in the infectious degree of different contagions: thus, that of the whooping-cough affects a much ſmaller proportion of mankind, than that of the meaſles, or ſmall-pox; and that of the ſcarlet fever excites the diſeaſe in children much more frequently than in adult perſons. Again, the contagion, in ſome inſtances of peſtilence, and, we believe, in the plague in general, is more fatal to the vigorous and middle-aged, than to the old on the one hand, or to children on the other. We were informed by a gentleman, who reſided at Malaga, during the late peſtilence at that place, that the appearance of the town, after the ceſſation of the fever, was remarkable, in conſequence of the ſmall number of ſtrong, active, and well-looking people, who were to be ſeen; old people and children conſtituting almoſt the whole of the remaining population. In the typhus, or contagious malignant fever of this country, Dr. Haygarth infers, from accurate deduction, that about eight in 188 eſcape infection, though fully expoſed to the contagion; which is leſs than *one* in *twenty-three*. (See Letter to Dr. Percival, p. 31.) It has been calculated that nearly the ſame number, or one in 20, is naturally exempted from the contagion of the ſmall-pox. Upon this datum it was alſo calculated, that if two perſons together have eſcaped the diſeaſe, the probability, that they were never both expoſed to an *infectious quantity* of the poiſon, is above 400 to one; if three in a family have eſcaped, above 8000 to one. (Haygarth's Inquiry how to prevent the Small-pox, p. 24.) This mode of reaſoning is equally applicable to typhous infection.

Now, as great numbers of people, viſitors, nurſes, &c. breathe the air of the chambers of patients, ill of contagious fever, and yet eſcape infection, it is obvious that in almoſt all theſe caſes, (at leaſt in 22 out of 23) a ſufficient *doſe* of the poiſon had not been received. This leads us to an important inquiry, into the doſe of typhous contagion requiſite to produce infection. The quantity will vary, no doubt, according to different circumſtances, but the obſervations of Dr. Haygarth, and of the phyſicians of fever-wards, and houſes of recovery, have enabled us to judge with ſome accuracy of the limits of this variation. There appears to be a ſtrict analogy between contagious miaſms and other poiſons. The larger the doſe of a poiſon or drug, the greater in general is the effect which it produces. Many of the moſt powerful and ſalutary medicines, when taken in too large a quantity, are poiſons, as opium, antimony, mercury, foxglove, hemlock, &c. And, on the other hand, even arſenic itſelf, the moſt virulent and unmanageable of all poiſons, has, by the ſkill and attention of phyſicians, been reclaimed from the claſs of miſchievous ſubſtances, and by a diminution of the doſe is juſtly held to be a ſafe and uſeful remedy. Farther, in different conſtitutions, and in different maladies, there is a certain degree of variety in the operation of any drug. Thus four or ſix times the doſe, *e. g.* of antimony or mercury, may be required for one patient more than for another, or for the ſame perſon in different diſeaſes. In the ſame way the miſchievous quantity of infectious miaſms admits of ſome variation.

It is clear, from the collected obſervations of Dr. Haygarth, and of thoſe active and experienced phyſicians whoſe correſpondence he has publiſhed, not to mention the experience which fever-wards have lately afforded, that in a large, airy, and clean apartment, few or none even of the moſt intimate attendants catch the diſeaſe, where the patient labours under infectious fever. The nurſes themſelves, expoſed to the effluvia of the excrements, and perpetually near, and often in contact with the ſick, nevertheleſs hardly ever receive infection. The atmoſphere of a room where contagion is generated, if cleanlineſs and ventilation are employed, may therefore be breathed for a long time with impunity. And it is not leſs clear, that an atmoſphere ſtrongly impregnated with contagion, may be breathed, for a ſhort time, with the ſame impunity. If we compare the numbers who eſcape infection after being expoſed to breathe a contagious atmoſphere, with the ſmall number who are naturally not ſubject to receive contagion, this propoſition muſt be obvious. But to ſtate facts. "During four years attendance in the hoſpitals of Edinburgh and London, and afterwards during thirty-one years in private practice in Cheſter, and fourteen years and a half in the Cheſter Infirmary, and three years at Bath, I have been," ſays Dr. Haygarth, "in the habit of breathing air ſtrongly impregnated with the infectious miaſms of fever. In many, very many, inſtances, I have viſited patients ill of infectious fevers, in ſmall, cloſe, and dirty rooms: yet never but once, above thirty years ago, had a fever. The phyſicians of the Mancheſter Infirmary for many years, and particularly during the late widely-ſpreading epidemics in that large and populous town, have, with great fortitude and humanity, conſtantly viſited the home patients; that is, they have, in innumerable inſtances, breathed the moſt peſtilential air, in the moſt concentrated ſtate. Their and my ſafety manifeſtly proceeded from this circumſtance; we remained but a ſhort time in the patients' room. We did not reſpire an infectious doſe of the poiſon." (Let. to Dr. Percival, p. 40.) We could multiply evidence upon this point to an indefinite extent, but the general ſafety of medical men under ſuch circumſtances is ſufficient to prove, that air ſtrongly impregnated with infectious miaſms may be breathed for a ſhort time, and air weakly impregnated for a long time, without any injury. We might hence be almoſt led to believe, that the poiſonous miaſms do not generate a fever, till they have been reſpired without interruption, for ſeveral days together: and it is not improbable that, in ſome perſons, ſuch an accumulated quantity of the poiſon may be required.

There are, however, other facts which prove that this is by no means always the caſe. Infection is occaſioned ſuddenly, in ſome inſtances, and from a very ſhort expoſure to a peſtilential air. Whether this is owing to peculiar ſuſceptibility of the individual, or to the particular mode of receiving the contagious effluvia, is doubtful. The writer of this article, about ſix years ago, viſited a poor family, of four perſons, lying in the ſame bed, in an exceedingly cloſe and dirty apartment, ill of contagious fever. He always had the precaution to throw open the window on entering the room, to ſtation himſelf between the window and the bed, whilſt he examined the ſick, and to remain but a ſhort time with them. He had repeated his daily viſits during a week, and with impunity, when he was at length accompanied by another phyſician, who deſigned to admit the patients into the Houſe of Recovery, juſt then opened in Gray's-inn-lane. The latter took no precaution, but examined the ſkin of the ſick minutely and cloſely, ſtanding on that ſide of the bed towards which the air from the window impelled the contagious effluvia, and ſo near as to receive theſe effluvia and the breath in the moſt concentrated ſtate. He took the infection, and his fever proved fatal. Here the infection of this excellent phyſician was attributable only to the full doſe of the poiſon, which his incautious zeal induced him to inhale. In moſt caſes, as in this, where a ſudden infection takes place, a diſagreeable ſenſation is excited at the moment of expoſure, which different perſons have deſcribed differently. Some have felt a ſharp taſte in the mouth, as if blue vitriol were diſſolving in it, but which no waſhing or gargling could remove. Others have compared the firſt impreſſion to that of an earthy exhalation from a newly-opened grave, the ſenſation extending down to the ſtomach, ſometimes exciting inſtantaneous ſickneſs and ſhivering. Dr. Haygarth mentions that two of his patients, who were phyſicians, were infected ſuddenly by a ſhort expoſure. One of them thought that he caught the fever by creeping behind, in order to aſſiſt, his patient; the other by inſpecting morbid fæces. In both theſe caſes, the expoſure was ſuch as might probably afford a full doſe of the contagion. Dr. Lind is of opinion, that, in theſe diſeaſes, the ſtools, eſpecially if very fœtid, are moſt communicative of contagion; next to theſe the breath; and laſtly the effluvia from the body.

The activity of contagion is not always proportionate to the appearances of malignancy in the diſeaſed. Sometimes only one man in a ſhip may be ſeized with the *petechial* or with the *yellow* fever, ſays Dr. Lind, while all the reſt continue unaffected. And the moſt malignant caſe of fever, that we ever witneſſed, did not infect any of the family, though in a cloſe and ſmall houſe. And on the contrary, we have ſeen fevers, of the mildeſt deſcription, which ſpread extenſively: ſo that we fully coincide with Dr. Lind in his obſervation, that "fevers have often no peculiar characteriſtic ſymptom, by which they are known to be infectious:" and again, when he ſays, "in ſome this fever will be more ſevere, in others more mild, and often moſt of the ſick will be able to ſit up through great part of the day, which cannot be urged as an argument againſt the infection, but only as a proof of its mildneſs." (Loc. cit. § v.) It is obvious, therefore, that great caution ſhould be uſed in pronouncing fevers *not* infectious.

The period at which different fevers begin and ceaſe to generate contagious effluvia is not abſolutely aſcertained. It ſeems moſt probable that in eruptive fevers there is no contagion till the eruption appears; and that contagion remains ſo long as any ſcab remains on the ſkin. This is clearly the caſe in ſmall-pox.

The latent period of contagion, as Dr. Haygarth terms it, or the period which elapſes between the expoſure to contagion and the firſt appearance of the diſeaſe which enſues, is aſcertained with tolerable accuracy in reſpect to the ſmall-pox; but in typhous caſes it appears to be extremely irregular. The ſmall-pox from inoculation uſually commences on the eighth or ninth day after the operation. Thus, of 810 inoculated caſes, in 519 fever commenced before the ninth, and 291 on or after the ninth day. But from the teſtimony of Drs. Woodville, Clark, and Currie, the eruptive fever ſometimes commences ſo early as the fifth day after inoculation; and three caſes are related by Dr. Clark where it commenced ſo late as the 16th, 17th, and 23d day. The latent period in the caſual ſmall-pox is ſomewhat longer than in the inoculated; moſt commonly from 10 to 16 days. (See Haygarth, Sketch, &c. before quoted.) The latent period of the contagion of meaſles is from 10 to 14 days. (Willan on Cutan. Diſ.) But the latent period of typhous infection is much more irregular, and often much longer. Of a large number of caſes ſtated by Dr. Haygarth, more than half commenced between the 17th and 33d day after expoſure, a great proportion after the 27th, and almoſt all between the 20th and 60th. (See Letter to Dr. Percival, p. 20. *et ſeq.*) The fever occurred in only five inſtances before the 10th day. So that on the whole, it appears, that the latent period of typhous infection varies from a few days to two months. (Ibid. p. 68.)

This latent infection is probably often allowed to lie long dormant, or is excited into action at an earlier period, according to the occurrence or non-occurrence of circumſtances which may render the conſtitution leſs capable of reſiſting its action. Thus perſons who had ſome time previouſly been expoſed to the influence of contagion, have been immediately taken ill upon being wet with rain, or on expoſure to a cold and damp air, or after a debauch, or other ſuch debilitating cauſes. During the prevalence of a peſtilence, it has been obſerved that expoſure to the damps of evening, eſpecially in warm countries, is extremely dangerous. And Dr. Chiſholm remarks, that thoſe who were addicted to the abuſe of intoxicating liquors, were moſt ſubject to the fever of Grenada. From the great length of time, indeed, which the contagion of fever often lies dormant, we may infer, with Dr. Lind, that it is probable, that, without the influence of theſe caſual exciting cauſes, the contagion might never, in ſuch inſtances, have affected the conſtitution.

Prevention of infection. The circumſtances under which contagion is generated, and the modes in which it is conveyed and propagated, being underſtood, the means of preventing its production, and of avoiding its pernicious influence, when it exiſts, will readily ſuggeſt themſelves. Inſtead of omitting all attempts at avoiding the contagion of a peſtilence, as altogether fruitleſs, where the very pabulum of life, the common air, is charged with poiſon; or of adopting the dangerous expedient of cloſing up every avenue of ventilation in our houſes (Wilſon on Fevers, p. 458. vol. i.), or of employing uſeleſs and abſurd meaſures of precaution, we ſhall proceed upon rational grounds to the uſe of effectual preventives. All thoſe who contend that the ſpreading of contagion depends upon ſome peculiar ſtate of the atmoſphere, admit that it is ſome *occult* quality in the air; that it is neither the heat nor the cold, the moiſture nor the dryneſs, nor any other ſenſible condition of it, with which peſtilence is connected. The great Sydenham, after having noted attentively the ſtate of the atmoſphere and the weather, in different years, during which epidemics of different kinds prevailed, was obliged to confeſs that he could perceive no difference in ſeaſons in which different contagious diſeaſes occurred. He, therefore, had recourſe to a ſuppoſition equally gratuitous, that ſome unwholeſome exhalations from the earth were the ſource of peſtilential diſeaſes.

But when it is conſidered, that contagion *originates* in accumulated and confined animal effluvia, and is *communicated* either to thoſe who approach, or come in contact with the ſick, or by means of ſubſtances impregnated with contagious matter, and in theſe ways only, the means of prevention are obvious.

With reſpect to the caſual origin of contagion, it is ſcarcely neceſſary to ſay, that cleanlineſs and ventilation, as they preclude the confinement and accumulation of the animal effluvia and ſecretions, will infallibly prevent the generation of the poiſon.

Where contagion exiſts, its farther communication may be prevented by avoiding contact or approach to the ſick, and by confining the patient to a ſeparate room, in which, if it be kept clean, and well ventilated, it has already been ſhewn, that the contagion will be inert, at a ſhort diſtance from the ſick; and therefore that the neceſſary attendants, and medical viſitors, will receive no injury from reſpiring the air within it. In this way contagion has been prevented from ſpreading in large ſchools, and other places, where a number of people live together, as in work houſes and hoſpitals, of which ſome examples have been already given. Dr. Haygarth's rules for the prevention of infection, ſeem to compriſe all the requiſite means to be adopted in houſes where contagious fever exiſts; they are the following.

Rules to prevent infection.

"1. As ſafety from danger entirely depends on cleanlineſs and free air, the chamber-door of a patient, ill of an infectious fever, eſpecially in the habitations of the poor, ſhould never be ſhut; a window in it ought to be generally open during the day, and frequently in the night. Such regulations would be highly uſeful both to the patient and nurſes; but are particularly important previous to the arrival of any viſitor.

"2. The bed curtains ſhould never be drawn cloſe round the patient; but only on the ſide next the light, ſo as to ſhade the face.

"3. Dirty clothes, utenſils, &c. ſhould be frequently changed, immediately immerſed in cold water, and waſhed clean when taken out of it.

"4. All diſcharges from the patient ſhould be inſtantly removed. The floor near the patient's bed ſhould be rubbed clean every day with a wet mop or cloth.

"5. The air in a ſick room has, at the ſame time, a more infectious quality in ſome parts of it, than in others. Viſitors and attendants ſhould avoid the current of the patient's breath,—the air which aſcends from his body, eſpecially if the curtains be cloſe,—and the vapour ariſing from all evacuations. When medical or other duties require a viſitor or nurſe to be placed in theſe ſituations of danger, infection may be frequently prevented by a temporary ſuſpenſion of reſpiration.

"6. Viſitors ſhould not go into an infected chamber with an empty ſtomach; and, in doubtful circumſtances, on coming out, they ſhould blow from the noſe, and ſpit from the mouth, any infectious poiſon which may have been drawn in by the breath, and may adhere to thoſe paſſages." (See Letter to Dr. Percival, p. 73. *et ſeq.*)

By obſerving theſe rules, not only numerous viſitors, but the medical attendants, and the nurſes themſelves, who frequently move and otherwiſe aſſiſt the ſick, in fever-wards, and the wards of houſes of recovery, entirely eſcape infection. This is proved, with ſcarcely any exception, in all the inſtitutions of this ſort throughout England and Ireland. During the laſt four years (the writer ſpeaks from perſonal obſervation) only one inſtance of infection ſeizing a nurſe in the London Houſe of Recovery, occurred, and, in that caſe, ſhe imprudently ſlept in a bed, juſt quitted by a convaleſcent, who had left the houſe, without changing the linen. By the ſame rules, Dr. Haygarth arreſted the progreſs of a ſcarlet fever and ſore throat in a ſchool, containing 37 boarders, at a time when Wincheſter and other great ſchools were diſperſing their ſcholars on account of this moſt contagious diſtemper, which had ſpread alarmingly among them. Not one was infected after the plan of ſeparation in an unviſited room was adopted, although all the boys remained in the ſame houſe. (Let. to Dr. Percival, p. 81.)

Contagion may, however, be extenſively circulated by *fomites*, i. e. attached to clothing, furniture, and other articles, which mode of communication is, perhaps, the moſt to be apprehended, during the prevalence of an epidemic malady. Hence the ſevere laws of quarantine have been enacted, in order to preſerve this country from the contagion of foreign peſtilence, which might be imported with the articles of commerce. And it is not leſs neceſſary, during times of internal peſtilence, to be watchful in regard to this point. It is not, however, by a ſlight and brief expoſure to contagious miaſms, that ſubſtances are ſufficiently imbued with them, to communicate infection. Thus it is, on the whole, well aſcertained that the clothes of viſitors do not acquire a peſtilential quality, ſo as to infect others. Upon this point, the experience of ſeveral obſerving practitioners coincides. Dr. Clark of Newcaſtle affirms, that in eighteen years practice, he never communicated the contagion of ſmall-pox, nor of the ſcarlet fever, with ulcerated ſore throat, to any one, even to children in his own family, although he had frequently, on the ſame day, viſited many patients in thoſe diſeaſes, and in the moſt malignant ſtages of the latter, and afterwards had intercourſe with other children liable to receive them. Mr. Henry adduces his own experience, during nearly forty years, in Mancheſter, in teſtimony of the ſame fact, in regard to the contagion of ſmall-pox. And the teſtimony of ſeveral other practitioners is equally ſtrong, as to the non-conveyance of this contagion by their clothes. Now, whatever is true of the contagion of ſmall-pox, and of ſcarlet fever, is ſtill more deciſive as to typhous infection, which is leſs powerful than either. (See Haygarth, Sketch of a Plan, &c. pp. 369, 386, 404, &c.) Subſtances do not become ſufficiently impregnated with the poiſon, in clean and ventilated places, except by being a conſiderable time in contact with, or very near the ſick, as the bed in which the patient lies, or the linen he wears; theſe *fomites* are chiefly produced in cloſe and dirty places, where the contagion is concentrated by accumulation and confinement, as in the cells of jails, or in the apartments of the poor; in which caſes, the utmoſt virulence of the poiſon is brought forth.

Where contagion of this degree of activity is produced, and is combined with articles of clothing and furniture, &c. the mere act of ventilation, which effectually prevents its deleterious action, when ariſing from the body of the ſick, is altogether inadequate to deſtroy its power in theſe *fomites*. Hence various means have been deviſed, in all ages, for annihilating contagion. Among theſe, fire has been moſt generally employed, more eſpecially with a view of fumigating, or applying the ſmoke or vapours from different ſubſtances, to the ſource of the poiſonous miaſms. Hippocrates and Acron of Agrigentum, believing the air to be the medium of infection, are ſaid to have ordered large piles of wood to be burnt in the ſtreets and infected parts of Athens, by which means they ſtayed the plague in that city. (Aetii *Tetrab.* Plutarch, de Iſid. et Oſir.) But however uſeful the fumigation of *fomites* may be, it does not appear to be of any utility when employed in the atmoſphere in general. In the year 1721, the plague raged at Toulon with ſuch violence, that in the ſpace of ten months it deſtroyed about two-thirds of its inhabitants. Many having inſiſted upon fires being made in different parts of the city, the public records were conſulted, and it was there found that, on a ſimilar occaſion, the ſame means had been tried without ſucceſs. The experiment, however, was repeated. Wood was laid before every houſe, and at the ſound of a bell, all the fires were lighted, by which the city was involved in a thick ſmoke for nearly a whole day. The plague, however, ſuffered no abatement. The ſame meaſure was reſorted to both at Marſeilles and London, when the plague raged in theſe cities, with no better ſucceſs. Nay, after the fires had been kept burning for three days in London, on the night which ſucceeded, no leſs than 4000 died, although not more than 12,000 had been deſtroyed during the preceding three or four weeks. (Wilſon on Feb. Diſ. vol. i. p. 464.)

There is no doubt, however, that contagion, adhering to clothes and furniture, may be effectually deſtroyed by the vapours from various combuſtible and volatile ſubſtances. Dr. Lind recommends the fumes of tobacco to be diſperſed through the cells and infected apartments, in priſons and ſhips, as well as for the purification of infected articles; he alſo adviſes the expoſure of fomites, to the fumes of ſulphur, from a charcoal fire, as an efficacious mode of purification. But he is perfectly convinced, he ſays, from long experience, that even the ſimple heat of a *cloſe confined* fire, or the heat of an oven, is a deſtroying power which "no infection whatever can reſiſt." The efficacy of gun-powder was aſcertained by an accident, and Dr. Lind afterwards uſed it in wards where fevers were received, every morning. In a ſhip of war, a contagious fever prevailed, which had deſtroyed ſixty men; when, in an engagement with the French, twenty-five barrels of gun-powder were fired on board of her during the action; and, to the ſurpriſe of her officers, none of her men were afterwards attacked with fevers.

Some ſtrong ſmelling ſubſtances, as camphor, the vapours of juniper, and of Caſcarilla bark, &c. have been occaſionally reſorted to as preventatives from contagion; but the power of theſe ſubſtances is very queſtionable, and they may be, perhaps, negatively prejudicial, as their aromatic odour may conceal the ſmell of bad air in the room of the ſick, and thus prevent effectual meaſures of ſafety from being employed.

The moſt efficacious of the means which we poſſeſs of deſtroying contagion in fomites, ſeem to be the fumes of the mineral acids. The vapours of vinegar, and thoſe of the ſulphureous acid, have been long uſed with ſome degree of ſucceſs; but thoſe of the muriatic, and ſtill more, perhaps, thoſe of the nitrous acid, appear to be complete antidotes to accumulated contagion. The evidence of the efficacy of the nitrous acid fume, in purifying infected places and ſubſtances, which was a few years ago laid before the Houſe of Commons by Dr. Carmichael Smyth, was ſuch as to induce that houſe to vote a national donation of five thouſand pounds to him for the diſcovery. This vapour is eaſily obtained, by mixing with powdered nitre a little of the ſtrong acid of vitriol or ſulphuric acid; the latter combines with the potaſs, the baſe of the nitre, expelling at the ſame time the nitrous acid in fumes. (See Dr. C. Smyth's treatiſe on the ſubject.) The vapour of the muriatic acid may be obtained in a ſimilar manner, by uſing common ſea or rock-ſalt, inſtead of nitre.

Where contagion has been long pent up in cloſe cells or rooms, it is apt even to adhere to the walls. In ſuch caſes, white-waſhing with hot or newly ſlaked lime, is an efficacious aid of the acid fumigations.

It is a curious fact, and perhaps wholly unaccountable upon any theory of the propagation of contagion, that peſtilential diſeaſes, after running an indefinite courſe, notwithſtanding all the meaſures adopted to reſtrain their progreſs, frequently ceaſe ſpontaneouſly, at a time when the walls of the houſes, furniture, &c. muſt ſtill be ſuppoſed to be highly impregnated with the contagion. The fact is authenticated by Dr. Ruſſell, Dr. Lind, and ſeveral other phyſicians of equal reſpectability. The ceſſation is not connected with any ſenſible changes in the atmoſphere. Warm weather is perhaps, on the whole, but not without many exceptions, more favourable to the production of contagious diſeaſes, than cold weather. But the worſt fevers have often raged in the coldeſt ſeaſons, as did the plague in London; and there have been inſtances of the plague ſuffering a check as the weather grew warmer. (Wilſon on Feb. Diſ. p. 448.)

During the prevalence of a contagious epidemic, temperance and regularity, and care in avoiding all cauſes of debility, (ſuch as cold damp air, &c.) the uſe of the cold bath, and the preſervation of an equal ſtate of mind, are great perſonal preſervatives. The general alarm which prevails during thoſe periods of public calamity, is not among the leaſt of the cauſes which contribute to extend the evil. It would be, therefore, injudicious to condemn the uſe of camphor, roſemary, and other aromatic ſubſtances, or carrying a quill filled with quickſilver, or other amulets, about the perſon, ſince whatever tends to inſpire confidence in the mind, contributes to the ſecurity of the body.

CONTARII, in *Antiquity*, a kind of horſemen, whoſe chief armour was the *contus*, a kind of long ſpear.

CONTARINI, Gaspard, in *Biography*, a cardinal of the church of Rome, was not more celebrated as a divine than as a politician. He flouriſhed in the Venetian territories, and was nominated from that republic as ambaſſador to the emperor Charles V., after which he was raiſed to a conſiderable ſtation in the government of his country. He was ambaſſador alſo to Rome; and when pope Clement VII. ſurrendered to the imperial army, a commiſſion was given to Contarini to negociate for the liberty of the pontiff. In 1535, he was created cardinal by pope Paul III.; and in 1541, he was appointed legate to Germany, and with the other legates was appointed to preſide at the general council, which was afterwards held at Trent; he was, however, ſent legate to Bologna, before that aſſembly met, where he died at the age of 59, in the year 1542. He was author of many works, and on various topics, in which he diſplays conſiderable talent, and a mind ſuperior to the times in which he lived. The principal pieces are "De Immortalitate Animæ," "De Septem Eccleſiæ Sacramentis," "De Poteſtate Papæ," "De Predeſtinatione," "De Libero Arbitrio," and "Confutatio Articulorum Lutheri."

Contarini, Vincent, a conſiderable ſcholar in claſſical literature and antiquities, was born at Venice, in 1577, and attained the profeſſorſhip of the Greek and Latin languages at Padua, which he held with great reputation till the year 1614, when he retired to Rome. From whence, taking a journey into Iſtria, he fell ill, and died at Venice in the prime of life, in 1617. The works by which he is chiefly known are "De Frumentaria Romanorum Largitione," and "De Militari Romanorum Stipendio." Moreri.

CONTARINO, Cav. Giovanni, an hiſtorical and portrait painter, who was born at Venice in the year 1549, and who ſtedfaſtly purſued the ſolid and pure ſtyle of Titian, notwithſtanding the pernicious example of almoſt all his rival compatriots, who, loſing the remembrance of thoſe glowing and rich tints which had ſo long been the boaſt of the Venetian ſchool, had adopted a manner in which the lights were ſo extravagantly contraſted by the moſt obſcure and cutting ſhadows, as to give to their pictures the appearance and gloom of midnight repreſentations. The principal works of Contarino are at Venice, and evince, independent of the beauties of colouring, a very competent knowledge of fore-ſhortening and the *ſotto in ſu*, with an excellent taſte of compoſition. One of his beſt and greateſt performances is the ceiling of the church of St. Franciſco di Paola, where, in the centre, he painted the Reſurrection of Chriſt, and on each ſide the Annunciation and Nativity, together with the Evangeliſts and the four Doctors of the Church. He executed ſeveral conſiderable works for the court of the emperor Ridolfus II., who conferred on him the honour of knighthood. His portraits bore ſo ſtrong a reſemblance to nature, that one of them, repreſenting Marco Dolce, is ſaid to have deceived his dogs and other domeſtic animals, who leaped up to the picture, ſuppoſing it their maſter himſelf. This artiſt died in the 56th year of his age, 1605. Lanzi, Storia Pittorica.

CONTAY, in *Geography*. See Conty.

CONTCHOUDSONG, a town of Aſia, in the country of Thibet; 380 miles E.N.E. of Laſſa. N. lat. 30° 20'. E. long. 97° 29'.

CONTE, del, Jacopino, in *Biography*, was born at Florence in 1510, and is ſaid in his youth to have received ſome inſtructions in painting, in the ſchool of Andrea del Sarto. Having completed his ſtudies, he ſoon gave proofs of ſuperior talents, both in hiſtorical and portrait painting. Rome, whither he was invited under pope Paul III., was the theatre of his labours, and he was employed to paint the portraits of that pontiff and of his ſucceſſor Clement VIII., as well as thoſe of the cardinals, the ambaſſadors, and other nobles of the court. In hiſtorical painting, he had no leſs ſucceſs; and the freſcoes, which he executed in the church of St. Giovanni Decollato, rank him amongſt the leaſt affected or extravagant of the imitators of Michelangelo. An altar-piece in the ſame church, repreſenting the taking down from the croſs, a compoſition of many figures, is conſidered his *chef d'ouvre*. He died at Rome in 1598. Baglione.

Conte, del, or Fassi, Guido, an artiſt who was born at Carpi, in the ſtate of Modena, in the year 1584, and was the firſt inventor of the *ſcagiiola*, a ſpecies of compoſition, or paſte, with which the fineſt marbles are with facility imitated, and which acquires ſufficient hardneſs to bear a poliſh. Some of the works of Guido, particularly two altars, are ſtill exiſting at Carpi, where he died in the year 1649.

This art has ſince been brought to ſuch a degree of perfection in ſeveral parts of Italy, that not only the fineſt marbles have been counterfeited, ſo as occaſionally to deceive the beſt judges; but likewiſe bas-relievos, vaſes, medals, and even pictures of great beauty, have been produced; inſomuch that it is become an article of commerce. (See Scagliola.) Lanzi, Storia Pittorica.

CONTEMPLATION, an act of the mind, whereby it applies itſelf to conſider, reflect on, and admire, the wonderful works of God, nature, &c.

Contemplation is the height of perfection of the myſtic divines. See Mystic.

CONTEMPORARY, or Cotemporary, a perſon, or thing, of the ſame time, or that exiſted in the ſame age, with another. Socrates, Plato, and Ariſtophanes, were contemporaries: the beſt hiſtories are thoſe of contemporary authors.

CONTEMPT, in the *Doctrine of the Paſſions*, is a ſpecies of hatred, expreſſing in its general ſenſe diſapprobation or averſion, which ariſes from the mere conſideration of a worthleſs object, eſpecially if it be propoſed to us under a pretence of its poſſeſſing excellence, or from miſconduct in things not of themſelves vicious; as, where a perſon either acts below his ſtation and character, or affects to do that for which he is not qualified. It is oppoſed to eſteem or to emulation. This is one of thoſe paſſions which in oratory belongs to demonſtrative diſcourſes. Thus Cicero (De Orat. lib. ii. c. 12.) endeavours to expoſe Cæcilius, and bring him into contempt of the court, for pretending to rival him in the accuſation of Verres, for which he was altogether unfit.

Contempt, in *Law*, is diſobedience to the rules, orders, or proceſs of a court, which hath power to puniſh ſuch offence; and a man may be impriſoned for a contempt done in court, but not for a contempt out of court, or for private abuſe. But for contempt out of court, an attachment may be granted. Cro. Eliz. 689.

Attachment alſo lies for contempt to the court, to bring in the offender to anſwer on interrogatories, &c. and if he cannot acquit himſelf, he ſhall be fined. 1 Lill. 305. If a ſheriff, being required to return a writ directed to him, doth not return the writ, it is a contempt: and this word is uſed for a kind of miſdemeſnor, by doing ſomething that is forbidden, or not doing what is commanded. 12 Rep. 36. As the degrees of this crime vary, the puniſhment is leſs or greater; ſometimes a mere fine, and ſometimes impriſonment.

If a defendant in chancery, on ſervice of a ſubpœna, does not appear within the time limited, by the rules of the court, and plead, demur, or anſwer to the bill againſt him, he is then ſaid to be in contempt; and the reſpective proceſſes of contempt are in ſucceſſive order awarded againſt him: theſe are attachment; attachment with proclamation; a commiſſion of rebellion; and, finally, a ſequeſtration. It is a contempt to inſtitute a ſuit fictitiouſly, though the demand is real, either to hurt any perſon, or to get the opinion of the court.

The moſt remarkable inſtances of contempts may be reduced to the following heads, *viz.* contempts of the king's writs; contempts in the face of a court; contemptuous words or writings concerning the court; contempts of the rules or awards of the court; abuſe of the proceſs of the courts; and forgeries of writs and other deceits tending to impoſe on the court. 2 Hawk. P. C. c. 22. § 3. For an account of the contempts that are puniſhed by attachment; ſee Attachment.

Contempts or miſpriſions (ſee Misprision) are offences againſt the king and government: ſuch is the mal-adminiſtration of high officers, in public truſt and employment, uſually puniſhable by the method of parliamentary impeachment, and ſubject to the penalties of baniſhment, impriſonment, fines, or perpetual diſability: ſuch is alſo the offence of embezzling the public money; and ſuch are thoſe contempts of the executive magiſtrate, which demonſtrate themſelves by ſome arrogant and undutiful behaviour towards the king and government. Contempts againſt the king's prerogative are a refuſal to aſſiſt him by advice in his councils, and by perſonal ſervice in his wars, againſt a rebellion or invaſion. To this claſs may be referred the neglect of joining the "poſſe comitatus," or power of the county, when required by the ſheriff or juſtices, according to the ſtatute 2 Hen. V. c. 8; which is a duty incumbent upon all that are 15 years of age, under the degree of nobility, and able to travel. Contempts againſt the prerogative are alſo a preference of the intereſts of a foreign potentate to thoſe of our own, and doing or receiving any thing that may create an undue influence in favour of ſuch extrinſic power; as by taking a penſion from any foreign prince, without the king's conſent; alſo, a diſobedience to the king's lawful commands, iſſuing by writs out of his courts of juſtice, or by ſummons to attend his privy council, or by letters from the king commanding a ſubject to return from beyond the ſeas: and likewiſe diſobedience to any act of parliament; all which contempts are puniſhable by fine and impriſonment, at the diſcretion of the king's courts of juſtice. Contempts and miſpriſions againſt the king's perſon and government may be by ſpeaking or writing againſt them, curſing or wiſhing him ill, giving out ſcandalous ſtories concerning him, or doing any thing that may tend to degrade him in the eſteem of his ſubjects, weaken his government, or excite jealouſies between him and his people. Contempts againſt the king's title, not amounting to treaſon or præmunire, are the denial of his right to the crown, in common and unadviſed diſcourſe; puniſhable by our law with fine and impriſonment. If any perſon affirm or maintain, that the common laws of this realm, not altered by parliament, ought not to direct the right of the crown of England; this is a miſdemeſnor, by ſtat. 13 Eliz. c. 1, and puniſhable with forfeiture of goods and chattels. A contempt may alſo ariſe from refuſing or neglecting to take the oaths, appointed by ſtatute for the better ſecuring of the government; and yet acting in a public office, place of truſt, or other capacity, requiring the ſaid oaths to be taken, *viz.* thoſe of allegiance, ſupremacy, and abjuration; which ſhould be taken within ſix calendar months after admiſſion. The penalties inflicted by ſtatute 1 Geo. I. ſtat. 2. c. 13, are little ſhort of thoſe of a præmunire; being an incapacity to hold the ſaid offices, or any other; to proſecute any ſuit; to be guardian or executor; to take any legacy or deed of gift; and to vote at any election for member of parliament: and after conviction the offender ſhall alſo forfeit 500*l.* to thoſe who will ſue for it. Contempts againſt the king's palaces or courts of juſtice have always been regarded as high miſpriſions; and by the ancient law, before the conqueſt, fighting in the king's palace, or before the king's judges, was puniſhed with death. And at preſent with us, by ſtat. 33 Hen. VIII. c. 12, malicious ſtriking in the king's palace, where he reſides, whereby blood is drawn, is puniſhable by perpetual impriſonment and fine at the king's pleaſure; and alſo with loſs of the offender's right hand. But ſtriking in the king's ſuperior courts of juſtice, in Weſtminſter-hall, or at the aſſiſes, is made ſtill more penal. By the ancient common law, before the conqueſt, it was a capital felony; and our modern law ſubſtitutes for the loſs of life that of the offending limb; the crime, and even drawing a weapon, being puniſhable with the loſs of the right hand, impriſonment for life, and forfeiture of goods and chattels, and of the profits of the offender's lands during life. (See Assault, &c.) A reſcue of a priſoner from any of the ſaid courts, without a blow, is puniſhed with perpetual impriſonment, and forfeiture of goods, and of the profits of lands during life. Even in the inferior courts of the king, an affray, or contemptuous behaviour, is puniſhable with a fine by the judges there ſitting; as by the ſteward in a court-leet, or the like. Thoſe alſo who are guilty of any injurious treatment to ſuch as are immediately under the protection of a court of juſtice, are puniſhable by fine and impriſonment. Laſtly, to endeavour to diſſuade a witneſs from giving evidence; to diſcloſe an examination before the privy-council; or to adviſe a priſoner to ſtand mute, are high miſpriſions and contempts of the king's courts, and puniſhable by fine and impriſonment. If one of the grand jury diſcloſes to any perſon indicted the evidence that appeared againſt him, he is guilty of a high miſpriſion, and liable to be fined and impriſoned. Blackſt. Comm. vol. iv.

CONTENEBRA, in *Ancient Geography*, a town of Italy, in Etruria, mentioned by Livy.

CONTENEMENT, a word, in our *Ancient Law-books*, about whoſe ſignification authors are not rightly agreed. According to ſome, it ſhould ſignify the countenance, credit, or reputation, a perſon has, from and by reaſon of his freehold. In which ſenſe it is uſed in the ſtat. 1 Edw. III. &c. where it ſtands as ſynonymous with *countenance.*

Others will have it ſignify what is neceſſary for the ſupport and maintenance of men, according to their ſeveral qualities, conditions, or ſtates of life. Thus, Spelman, *Contenementum eſt æſtimatio, & conditionis forma, qua quis in republica ſubſiſtit.* And in this ſenſe it occurs in Magna Charta, cap. 14.

CONTENSON, Vincent, in *Biography*, a French Dominican monk, was born at Condom, in 1640, and celebrated in his time for conſiderable pulpit talents. He left behind him a work of reputation, entitled, "Theologia mentis et cordis," which has paſſed through ſeveral editions in folio and in octavo.

CONTENT, in *Mathematics*, a term frequently uſed for the capacity of a veſſel, or the area of ſpace; or the quantity of any matter, or ſpace, included in certain bounds. The content of a tun of round timber is 43 ſolid feet. A load of hewn timber contains 50 cubic feet: in a foot of timber are contained 1728 cubic or ſquare inches, and as often as 1728 inches are contained in a piece of timber, be it round, or ſquare; ſo many feet of timber are contained in the piece.

In gauging, the gallon for beer and ale is allowed to contain 282 cubic inches, and the wine gallon 231; the gallon of dry meaſure 272.

Hence, as oft as 282 cubic inches are contained in any veſſel, round or ſquare; ſo many gallons of ale or beer it holds; and the like may be obſerved of the other meaſures.

Multiply, therefore, one ſide of a ſquare, or oblong, into the other; and divide by one of thoſe numbers, according to the quality of the liquor; the quotient gives the area in gallons, upon an inch deep.

Though the work may be conſiderably ſhortened by only multiplying the ſides of ſquares, or the diameters of rounds, into themſelves; the product is the number of gallons, and parts, the veſſel contains, upon an inch in depth: and when that receives an augmentation, by being two, three, or four inches deep, it then commences a ſolid body, and contains as many gallons, and parts, as it has inches and parts deep.

A cubic foot contains ſix gallons and almoſt a pint of ale and beer; and ſeven gallons two quarts of wine. A cubic foot of dry meaſure contains ſix gallons and a half, and ſomething more. A buſhel of ſalt contains 56 pounds avoirdupoiſe. See Gauging.

CONTENTIOUS Jurisdiction, in *Law*, denotes a court, or aſſembly, which has a power to judge and determine differences between contending parties.

The lords chief juſtices, judges, &c. have a *contentious juriſdiction;* but the lords of the treaſury, the commiſſioners of cuſtoms, &c. have none; being merely judges of accompts and tranſactions.

CONTENTMENT, in *Pathology* and *Ethics*, expreſſes the acquieſcence of the mind in the poſſeſſion of the good that is aſſigned to us. It implies a perception that our lot might have been better, or that it is inferior to what others enjoy, or that it does not fully anſwer the expectations we had formed. An effort of reaſon, or of prudence, or of religious principles, is neceſſary to produce it. We compare our preſent with our former ſituation, or with the inferior lot of others; and thus learn to acquieſce in the degree of advantage which we have obtained. A regard to the diſpoſals of Providence, wiſe, righteous, and benevolent, will very much contribute to the acquiſition and exerciſe of the virtue of contentment.

CONTESSA, in *Geography*, a ſmall town of European Turkey, in the province of Macedonia, ſituated in the bay of the ſame name, with a good harbour, on the coaſts of the Archipelago; 54 miles N.E. of Salonica. Long. 41° 35′. At the entrance of the gulf of Conteſſa is ſituated the iſland of *Taſſo*. The French navigators alſo call this bight "Golfe de Rhondine," from the corrupted name of the ancient town of *Rhedine;* but the Greeks deſignate it under the name of *Orfano*. It is the *Sinus Strymonicus* of the ancients.

CONTESTANI, in *Ancient Geography*, a people of Hiſpania Citerior, to the ſouth of the Edetani. Their territory extended ſouthwards as far as Betica, or at leaſt to the extremity of the Tarragonenſis, where are found ſome places dependent on the Baſtitani, who inhabited part of the eaſtern Betica.

CONTESTANIA, a country of Spain, in the Tarragonenſis, mentioned both by Pliny and Ptolemy. The former ſays, that this country was firſt called "Mavitania," afterwards "Deitania," and then *Conteſtania*. Here theſe authors place the river Tader, the colony of Illici, Lacentum, Dianium, the river Sacro, &c.

CONTESTATIO Litis, among *Civilians*, denotes a general aſſertion that the plaintiff hath no ground of action, which aſſertion is afterwards extended and maintained in his plea.

CONTEXT, among *Divines* and *Critics*, that part of Scripture, or other writing, which lies about the text, before or after it, or both. To take the full and genuine ſenſe of the text, the context ſhould be regarded.

CONTEXTURE, a word frequently uſed in ſpeaking both of the works of nature and art; and denoting the diſpoſition and union of the conſtituent parts with reſpect to one another.

CONTHIL, in *Geography*, a town of France, in the department of the Meurthe, and diſtrict of Chateau-Salins; 2 leagues N.N.W. of Dieuze.

CONTHILA, in *Ancient Geography*, a borough of Greece, in Attica; placed by ſome in the Ptolemaide tribe, and by others in the Pandionide.

CONTI, Giusto De, in *Biography*, an Italian poet and lawyer. His verſes are chiefly amatory; and they appeared under the title of "Bella Mano," on account of the beautiful hand of his miſtreſs, which is the ſubject of frequent adulation. He died in 1409, and his poems have been publiſhed at Venice, Paris, Verona, and Florence. He has been compared to Petrarch; but the beſt judges have regarded him as much inferior to that writer. Moreri.

Conti, Cesare and Vincenzio, two brothers, the former, a native of Ancona, was celebrated as an expeditious painter of groteſques; the latter, born at Rome, was a painter of hiſtory.

Baglione enumerates many conſiderable works, in which both theſe artiſts were employed at Rome, under the pontificate of Sixtus V. and Gregory XIII. Vincenzio ultimately ſettled in Turin, where he was taken into the ſervice of the duke of Savoy. They both died during the pontificate of Paul V. Baglione.

Conti, Domenico, of Florence, was the beloved diſciple of Andrea del Sarto, and heir to his deſigns and ſtudies. In gratitude and veneration to the memory of his great maſter, Conti, at his own expence, erected the monument ſtill remaining in the cloiſter of the Nunziata, where the buſt of Andrea is finely ſculptured by the hand of Raffaello di Monte Lupo. Of Domenico's works in painting little is now known. Orlandi.

Conti, Carlo, an engraver, native of Lorraine, in 1742. He eſtabliſhed himſelf at Vienna, where he was reputed a good artiſt. He was living in 1790. Heinecken.

Conti, Francesco, an hiſtorical painter, born at Florence, in the year 1681. He travelled to Rome, where he became the diſciple of Carlo Maratti. On his return, he acquired ſufficient reputation to merit a place in the celebrated collection of portraits in the Florentine gallery. He died in the year 1760. Lanzi, Storia Pitt.

Conti, Luca, an engraver and architect, who was born in 1749, and became the diſciple of Cleriſſeau. He eſtabliſhed himſelf at Paris, where he continued to follow his profeſſion in 1790. Heinecken.

Conti, Gioachino. See Gizziello.

CONTIGLIANO, in *Geography*, a town of Italy, in the duchy of Spoleto, near a lake to which it gives name; 3 leagues W. from Rieti.

CONTIGNE, a town of France, in the department of the Maine and Loire, and diſtrict of Segré; 3 miles N. of Chateauneuf.

CONTIGUITY, the relation of bodies touching one another. See Continuity.

CONTIGUOUS, a relative term, underſtood of things diſpoſed ſo near each other, that they join their ſurfaces, or touch.

The houſes in ancient Rome were not contiguous as ours are, but all inſulated.

Contiguous *angles*, in *Geometry*, are ſuch as have one leg common to each angle; otherwiſe called *adjoining angles*, in contradiſtinction to thoſe produced by continuing their legs through the point of contact, which are called *oppoſite* or *vertical angles*.

CONTINENCE, in *Ethics*, a moral virtue, by which we reſiſt concupiſcence. It ſhould ſeem that there is this diſtinction between *chaſtity* and *continence*, in that it requires no effort to be chaſte, which reſults from conſtitution; whereas *continence* appears to be the conſequence of victory gained over ourſelves. The verb *continere*, in Latin, ſignifies *to reſtrain*.

CONTINENT, in *Geography*, a terra firma, main land, or a large extent of country, not interrupted by ſeas: ſo called, in oppoſition to *iſland*, *peninſula*, &c. See Earth, Ocean, &c.

Sicily is ſaid to have been anciently torn from the continent of Italy; and it is an old tradition, which ſome of our antiquaries have ſtill a regard to, that Britain was formerly a part of the continent of France.

Mr. Kirwan ſuppoſes (ſee Iriſh Tranſ. vol. vi. p. 298.) that, when by the rupture of the Thracian Boſphorus, or iſthmus which connected the Caſpian, the lake of Aral, and the Black Sea, on the one ſide, and of the African iſthmus, which joined Ceuta with Gibraltar on the other, the waters of the Ocean and of the Euxine were forced in upon the Mediterranean, an immenſe preſſure took place upon its bed, under which it ſunk or fell into the interior cavity of the globe; during this tremendous tumult the iſlands of Sicily, Sardinia, Corſica, and thoſe of the Archipelago, were torn off from the Continent, and Italy was lengthened to its preſent ſhape. The ſeparation of Sicily from Italy is vouched by ancient traditions, as may be ſeen in Pliny, Ovid, and Claudian.

> "Zancle quoque juncta fuiſſe
> Dicitur Italiæ, donec confinia pontus
> Abſtulit, et mediá tellurem repulit unda."
> Ovid. Met. l. xv. v. 290.
>
> "Trinacria quondam
> Italiæ pars una fuit, ſed pontus et ceſtus
> Mutavere ſitum, rupit confinia Nereus,
> Victor, et abſciſſo interluit æquore montes."
> Claud. de Rep. Proſ. l. 1.

The entire ſeparation of Great Britain from the Continent muſt have happened long after the deluge, and that of Ireland from Great Britain at a ſtill later period; for wolves and bears were anciently found in both, and theſe muſt have paſſed from the Continent into Britain, and hence into Ireland, as it cannot reaſonably be ſuppoſed that they were imported thither. The divulſive force, ſays Kirwan (*ubi ſupra*), that ſeparated Britain from Germany, ſeems to have been directed from North to South, but gradually weakened in its progreſs. Hence that iſland is ſharpened northwards; but the impreſſion muſt have been conſiderably weakened by the oppoſition of the granitic mountains that form the Shetland and Orkney iſles. The rupture of the iſthmus that joined Calais and Dover was probably effected by an earthquake at a later period, and gradually widened by tides and currents. Ireland was protected by Scotland from the violence of the northern ſhock; and therefore its ſeparation from Scotland appears to have been late and gradual. That from England was probably diluvial, and effected by a ſouthern ſhock. All theſe changes happened 3600 years ago; and there is no reaſon for thinking that the general level of the ocean has been ſince altered; but that of the continents ſeems to have varied conſiderably, being in ſome places higher and in ſome lower than it was in ancient times.

The world is ordinarily divided into two grand continents; the Old and the New; the Old comprehends Europe, Aſia, and Africa; the New the two Americas, North and South.

The ſeparation of the two continents Kirwan (*ubi ſupra*) ſuppoſes to have probably been the effect of excavation by volcanos; at leaſt, he ſays, this cauſe is adequate to ſuch an effect, and it ſtill exiſts in the moſt northern parts; the ſuperior fertility of the weſtern coaſt of America may ariſe from the lavas ejected on that coaſt. But however this ſeparation was effected, we have no traditional account of it, and the period in which it happened is no leſs difficult to be aſcertained than the cauſes which produced it.

M. Buffon affirms, that they were not ſeparated when the elephants lived equally in the north of Europe, Aſia, and America, the bones of which have been found in Ruſſia, Siberia, and Canada. Hence he concludes, that the ſeparation of the two Continents muſt have happened after the abode of theſe animals in the northern regions. But it has been doubted whether the remains of elephants and of the rhinoceròs that have been lately found in Siberia, even allowing that the temperature of this country was ever ſo ſuited to the conſtitution of theſe animals as to admit of their living in it, belonged to animals which ever lived in it. As to the mode of their formation, we have different conjectures and theories, of which an account will be given under the articles DELUGE and EARTH.
